

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THERAPEUTICS:

ITS

PRINCIPLES AND PRACTICE.

BY
H. C. WOOD, M.D., LL.D.,
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, AND CLINICAL PROFESSOR OF DISEASES OF
THE NERVOUS SYSTEM, IN THE UNIVERSITY OF PENNSYLVANIA.

A WORK ON MEDICAL AGENCIES, DRUGS AND POISONS,
WITH ESPECIAL REFERENCE TO THE RELATIONS BETWEEN PHYSIOLOGY AND
CLINICAL MEDICINE.

THE NINTH EDITION OF
A TREATISE ON THERAPEUTICS,
THOROUGHLY REVISED.

PHILADELPHIA:
J. B. LIPPINCOTT COMPANY.
LONDON: 10 HENRIETTA STREET.
1894.

1

Entered, according to Act of Congress, in the year 1875, by

J. B. LIPPINCOTT & CO.,

In the Office of the Librarian of Congress, at Washington.

Copyright, 1879, 1882, and 1883, by J. B. LIPPINCOTT & Co.

TO
DR. GEORGE B. WOOD, LL.D.,
THIS BOOK
IS DEDICATED BY THE AUTHOR, HIS NEPHEW,
AS A
TOKEN OF RESPECT AND AFFECTION.

PREFACE TO THE NINTH EDITION.

IN offering the ninth edition of the present treatise to the kind consideration of his medical brethren and of those who wish to become medical brethren, the author desires to express his high appreciation of the continuous favor with which his work has been viewed by his co-laborers, and to state that every effort has been made on his part to maintain whatever of excellence may have been in previous editions. As a matter of course, the book has been thoroughly adapted to the new Pharmacopœia of the United States, and such new official remedies as *Aspidosperma*, *Naphtol*, *Hydrastinine*, and the *Strontium Salts* have been very carefully and elaborately discussed. Careful consideration has also been given to various new non-official candidates for professional use; among these may be mentioned *Gold Bromide*, *Pental*, *Chloralose*, *Chloralamid*, *Piperazine*, *Trional*, *Tetronal*, *Tropacocaine*, *Cresol* and its preparations. Throughout there has been a constant endeavor to eliminate effete material and to incorporate all the numerous discoveries of the last three years. In a treatise like the present it is important to keep the volume as small as is consistent with clearness and thoroughness of study, but the growth of the science of Therapeutics in the three years has necessitated the addition of nearly one hundred pages.

▲

PREFACE TO THE FIRST EDITION.

At the present time, when the shelves of private and public libraries are groaning beneath their ever-increasing loads, when a thousand presses in every city send forth day and night their printed messages until the earth is filled with them, it seems almost presumptuous for any one to offer new volumes to the world. Indeed, art is so long, life is so short, that every student has the right to demand of an author by what authority he doth these things, and to challenge every memoir for its *raison d'être*. This being so, it assuredly will not appear egotistical for the author to state that his voluntary task was first suggested by his own wants, and that to its performance he has brought the training, labor, and experience of years spent in the laboratory, the study, the class-room, and the hospital ward.

There are a number of excellent treatises upon materia medica and therapeutics; yet in various attempts at original research, as well as in the ward and the lecture-room of the hospital, I have keenly felt the want of something more. There are many points of view from which a subject can be looked at; there are many paths by which it may be approached; and to me, other points of view, other modes of approach, have been far more enticing than those adopted in our standard treatises.

The old and tried method in therapeutics is that of empiricism, or, if the term sounds harsh, of clinical experience. As stated by one of its most ardent supporters, the best possible development of this plan of investigation is to be found in a close and careful analysis of cases before and after the administration of a remedy, and, if the results be favorable, the continued use of the drug in similar cases. It is evident that this is not a new path, but a highway already worn with the eager but weary feet of the profession for two thousand years.

That very much has been thus accomplished it were folly to deny. Leaving out of sight the growth of the last two decades, almost all of the current therapeutic knowledge has been gained in this way.

Therapeutics developed in this manner cannot, however, rest upon a secure foundation. What to-day is believed is to-morrow to be cast aside, certainly has been the law of advancement, and seemingly must continue to be so. What has clinical therapeutics established permanently and indisputably? Scarcely anything beyond the primary facts

that quinia will arrest an intermittent, that salts will purge, and that opium will quiet pain and lull to sleep.

To established therapeutic facts the profession clings as with the heart and hand of one man,—clings with a desperation and unanimity whose intensity is the measure of the unsatisfied desire for something fixed. Yet with what a Babel of discordant voices does it celebrate its two thousand years of experience!

This is so well known that it seems superfluous to cite examples of the therapeutic discord; and one only shall be mentioned, namely, rheumatism. In this disease, bleeding, nitrate of potassium, quinine, mercurials, flying blisters, purgation, opium, the bromides, veratria, and a host of other remedies, all have their advocates clamorous for a hearing; and above all the tumult are to be heard the trumpet-tones of a Chambers, "Wrap your patients in blankets and let them alone."

Experience is said to be the mother of wisdom. Verily she has been in medicine rather a blind leader of the blind; and the history of medical progress is a history of men groping in the darkness, finding seeming gems of truth one after another, only in a few minutes to cast each back to the vast heap of forgotten baubles that in their day had also been mistaken for verities. In the past, there is scarcely a conceivable absurdity that men have not tested by experience and for a time found to be the thing desired; in the present, homœopathy and other similar delusions are eagerly embraced and honestly believed in by men who rest their faith upon experience.

Narrowing our gaze to the regular profession and to a few decades, what do we see? Experience teaching that not to bleed a man suffering from pneumonia is to consign him to an unopened grave, and experience teaching that to bleed a man suffering from pneumonia is to consign him to a grave never opened by nature. Looking at the revolutions and contradictions of the past,—listening to the therapeutic Babel of the present,—is it a wonder that men should take refuge in nihilism, and, like the lotos-eaters, dream that all alike is folly,—that rest and quiet and calm are the only human fruition?

Since the profession has toiled so long and found so little, if further progress is to be made we must question the old methods and search out new ones, which haply may lead to more fruitful fields. In the ordinary affairs and business of life, when anything is to be accomplished, the effort always is to discover what is to be done, and then what are the means at command. A primary knowledge of the end to be accomplished, and a secondary acquaintance with the instruments, are a necessity for successful human effort; and until the sway of this law is acknowledged by physicians, medicine can never rise from the position of an empirical art to the dignity of applied science. Until within a comparatively recent period, it has been impossible to comply with this law. But, through the advances made by the pathologists

and by the students of the natural history of disease, we are fast learning the methods in which nature brings the body back to health. When this is done,—when disease is thoroughly understood,—we shall have wrought out the first element of the problem, shall have complied with the first requirement of the law.

It is scarcely within the province of the therapist, and certainly is not possible within the scope and limits of this work, to discuss at length the natural history of disease; but it is allowable to point out evident indications for relief; and this I have done to a greater or less extent throughout the book.

The work of the therapist is chiefly with the second portion of the law. Evidently, it is his especial province to find out what are the means at command, what the individual drugs in use do when put into a human system. It is seemingly self-evident that the physiological action of a remedy can never be made out by a study of its use in disease. Under all circumstances, the problem is one of the most complex with which the human mind has to grapple; and to introduce into this problem the new and ever-varying factors of the effect of disease and its natural vibrations on the system is to put the matter beyond human prescience.

In spite, then, of Dr. Niemeyer's assertion that experiments made with medicaments upon the lower animals or upon healthy human beings have, as yet, been of no direct service to our means of treating disease, and that a continuation of such experiments gives no prospect of such service, it is certain that in these experiments is the only rational scientific groundwork for the treatment of disease. We must discover what influence a drug exerts when put into the body of a patient before we can use it rationally; and we can gain this coveted knowledge only in the method indicated.

It has been strenuously objected, especially to experiments upon animals, that drugs do not act upon the lower creatures in the same manner as they do upon man. When I first commenced the studies whose outcome is the present volume, I was profoundly impressed with the truth of this oft-repeated assertion and with the difficulties which it put in the way. To-day I do not believe that, stated in its broad sense, it is true. Indeed, more strongly, I assert that it is not true; that, in the vast majority of cases, the actions of drugs upon man and upon the lower animals are, though seemingly different, in reality similar; that the more knowledge we acquire, the fewer exceptions remain unexplained; and that the whole matter is in all probability subject to laws whose development will greatly aid in our explanation of various obscure clinical phenomena.

The general proofs of these assertions are sufficiently obvious, I think, in the following pages to render it unnecessary for me to dwell upon them at length here: moreover, if they be not so obvious to others as to myself, space is here wanting for a full discussion of the

subject. I can only make a few general remarks, and point out some of what I believe to be the governing laws.

In the first place, degree and quality are distinct things, and should not be confounded. Yet they frequently are; and because it requires as much morphia to kill a pigeon of a pound weight as to destroy a man, we are told that medicines act differently upon man and the lower animals. Evidently the conclusion is a non-sequitur, and difference of susceptibility is no proof of difference in the mode of impression. A teaspoonful of Epsom salt may purge one man, while it may require ounces to affect another. Evidently there is a difference of susceptibility; but when the impression is once made it is of the same character in each case. As with man and man, so with man and the pigeon,—susceptibility is no measure or gauge of the character of the impression.

A large number of drugs—indeed, it may be said, the larger number of important drugs—exert in the system antagonistic actions. Thus, atropia stimulates the spinal cord, but destroys the conducting power of the nerve-trunks. It is evident that as one or the other of these influences predominates, will there be convulsions or paralysis. Now, if for any reason one animal be exceedingly sensitive to the spinal action of atropia, that animal will in belladonna-poisoning suffer from convulsions, while its fellow, which is affected chiefly by the nerve-action of the drug, will, under like circumstances, have paralysis. Here the mere clinician, with his superficial knowledge, seeing the paralyzed and the convulsed lying side by side, says, What a hopeless muddle! Poor fools, these vivisectors! they will never come to any good! In truth, the differences in symptoms in these and in many other cases simply depend upon differences in susceptibility; and the only lesson that the circumstance teaches is the importance of discovering the laws which govern these susceptibilities.

A law which governs the susceptibility to the action of drugs is, that the more highly specialized any system is, the more readily affected is it by a medicine. Thus, the cerebrum of a man is far more highly organized than that of any other animal, and consequently he is far more sensitive to the action of drugs which affect the cerebrum than are the lower forms. Again, in the frog the spinal system is especially developed,—probably, in proportion to the cerebrum, more so than in any other of the animals commonly experimented with: consequently the batrachian is excessively sensitive to remedies which, like strychnia, affect the spinal cord. In obedience to this law, we have resulting the action of opium,—an action which has been considered the strongest proof of the hopelessness of any attempt to explain the effects of drugs upon a man by experiments upon the lower animals. In man, opium causes deep stupor and general relaxation; in the frog, it causes tetanic convulsions. The explanation of these seeming inconsistencies is, however, very evident when the whole subject is looked at. Opium in all animals has a double action, one upon the cerebrum and one upon

the spinal centres. In the frog, the latter being the more highly organized, the spinal action overcomes the cerebral; in man, the cerebrum being the more sensitive, stupor replaces the convulsions: yet in man convulsions sometimes occur in opium-poisoning, and in the frog the dose can be so managed as to cause stupor.

A second law which seems to hold away over the action of drugs upon different animals is that great differences of function in a system affect its relation to drugs: thus, in a herbivorous animal the alimentary canal is very different from what it is in the carnivora, whose digestive organs in turn differ from those of man,—the omnivore. Medicines which act upon the alimentary canal are apt to vary in their effects upon different orders of animals.

Converse to the above law is that which renders systems which are little specialized similarly acted upon by drugs in different classes of animals.

Thus, the general structure and the functions of the circulatory system are very uniform among vertebrates, as is also the action of those drugs which affect chiefly the circulation: thus, aconite, or digitalis, or potash, influences in the one way the heart of the frog, of the rabbit, and of man.

There are a very few apparent exceptions to the uniformity of the action of drugs upon all animals, which seemingly contravene the laws that have been mentioned. These exceptions are so few, however, that without doubt advancing knowledge will by and by explain them all and show what are the laws which for the time being hold in abeyance or overcome those already stated.

An asserted fact which has recently been brought forward as revealing the worthlessness of animal experimentation is that some monkeys are not susceptible to the action of strychnia, while others are. Granting the truth of the asserted fact, it certainly is explainable. It is at least conceivable that a given species of animal may, by the gradually-acquired habit of feeding upon a substance containing a narcotic poison, acquire an insusceptibility to the influence of that poison which shall as it were belong to its specific type, or, in other words, be an acquired specific character. The nervous system of the opium-eater becomes accustomed to the stimulant, and it is not impossible that a measure of the habit should be transmitted. If the Darwinian law of the gradual evolution by the survival of the fittest have any force, these curious apparent freaks of medicines in regard to their physiological action may be the result of this law, especially since it is species which are affected. It is not all monkeys that are proof against strychnia, but, as we are distinctly told, only one species of monkey; and, so far as I know, it is not all deer that are said to thrive when fed upon tobacco, but only the Virginia deer. Whether this conception be or be not a mere fancy, this much is to my mind very clear, that the few scattered exceptions ought not to outweigh the immense mass of

evidence upon the other side, and that it is inconceivable that drugs, in their relations to animal organisms, differ from all other created things in not being subject to law.

In the early portion of this preface I stated that the work had grown out of a need felt by myself: that need was for a book into which should be gathered the many scattered facts in regard to the physiological action of medicine,—a book in which an attempt should be made to sift the true from the false, to reconcile seeming differences, to point out what we know and what we do not know, and to give a platform from which investigators might start forward without the necessity of being, as is so often the case, ignorant of what was already achieved, or of spending a great deal of time in a wild hunt through the almost boundless, but often scattered and inaccessible, ranges of Continental literature.

The plan of the present work has been to make the physiological action of remedies the principal point in discussion. A thoroughly scientific treatise would in each article simply show what the drug does when put into a healthy man, and afterwards point out to what diseases or morbid processes such action is able to afford relief. Unfortunately, in the great majority of cases our knowledge is not complete enough for this, and the clinical method has to be used to supplement the scientific plan.

I have added to the book a consideration of toxicology, so far as it is of interest to the physician. This has been done for several reasons. First, it was necessary to study the action of poisonous drugs upon man, in order to make out their physiological action; secondly, physicians are constantly required to diagnose and to treat cases of poisoning; thirdly, it is often of the greatest importance for a medical man in a court of law to be able to state what are the symptoms and post-mortem appearances produced by a given poison, what diseases they simulate, and how far and in what they differ from the phenomena of these diseases. That part of the science of toxicology which treats of the recognition of poisons in the cadaver, or in food and drink, belongs to the domain of the chemist, and I have avoided it altogether. For a similar reason, in the sections on *materia medica*, the chemical relations of mineral substances have not been discussed at all.

TABLE OF CONTENTS.

INTRODUCTION.

PART I.

REMEDIES, REMEDIAL MEASURES, AND REMEDIAL METHODS WHICH ARE NOT DRUGS.

Preliminary Considerations.

CHAPTER I.—General Considerations; Massage; Feeding of the Sick, including General Considerations, Liquid Meat Foods, Milk Foods, Artificially-Digested Foods; Metallo-Therapy.

CHAPTER II.—The Treatment of Systemic States, including Exhaustion and Neurasthenic Conditions, Corpulence, and Lithiasis.

CHAPTER III.—CALORIC: Use of Cold; Local Employment of Cold; Cold as a Tonic and Stimulant; Cold in Pyrexia.

CHAPTER IV.—ELECTRICITY: General Considerations, including Electrical Physics and Physiology as applied to Human Medicine; Employment of Electricity for the Diagnosis, Prognosis, and Therapeutics of Motor and Sensory Affections; Application of Electricity to the Nerve-Centres, and Use as a Tonic; Magnetism.

PART II.

DRUGS.

Preliminary Considerations; Pharmacy; Therapeutics; Pharmacology; Preparations; Indications for the Use of Medicine; General Methods of Therapeutics, including Homœopathy; Modes of Administration; Doses, and the Circumstances that modify them; the Art of Prescribing and Combining Medicines.

DIVISION I.—SYSTEMIC REMEDIES.

CLASS I.—GENERAL REMEDIES.

ORDER I.—NERVINES.

FAMILY I.—ANTISPASMODICS: Musk; Castor; Valerian; Asafetida; Camphor; Oil of Camphor; Monobromated Camphor; Carbolated Camphor; Amber and its Oil; Hoffman's Anodyne; Hops; Lactucarium; Cimicifuga.

FAMILY II.—ANÆSTHETICS: Nitrous Oxide; Ether; Chloroform; Ethyl Bromide; Pental; Practical Anæsthesia; Methylene Bichloride; Bromoform.

TABLE OF CONTENTS.

FAMILY III.—SOMNIFACIENTS: Opium; Morphine; Narceine; Codeine; Narcotine; Thebaine; Papaverine; Laudanine; Porphyroxine; Cryptopine; Meconine; Hydrocotarnine; Hyoscine; Scopolamine; Chloral; Metachloral; Chloralamid; Chloralose; Chloral Camphor; Butyl-Chloral Hydrate; Sulphonal; Trional; Tetronal; Paraldehyde; Amylene Hydrate; Urethan; Hypnone; Methylal.

FAMILY IV.—DELIRIFACIENTS: Cannabis Indica; Cannabene; Belladonna Leaf and Belladonna Root; Atropine; Homatropine; Stramonium; Hyoscyamus; Coca; Cocaine; Tropacocaine.

FAMILY V.—EXCITO-MOTORS: Nux Vomica; Strychnine; Brucine; Ignatia.

FAMILY VI.—DEPRESSO-MOTORS: Calabar Bean; Potassium Bromide; Ammonium Bromide; Sodium Bromide; Lithium Bromide; Hydrobromic Acid; Bromal Hydrate; Gold Bromide; Amyl Nitrite; Potassium Nitrite; Sodium Nitrite; Nitroglycerin; Amyl Valerianate; Lobelia; Gelsemium; Tobacco Conium.

FAMILY VII.—RESPIRATORY STIMULANTS AND DEPRESSANTS: Aspidospermamine; Aspidospermatine; Aspidosamine; Quebrachine; Hypoquebrachine; Quebrachamine.

ORDER II.—CARDIANTS.

FAMILY I.—CARDIAC STIMULANTS: Ammonium and its Salts; Alcohol; Digitalis; Caffeine; Convallaria Majalis; Strophanthus; Sparteine; Adonidin.

FAMILY II.—CARDIAC DEPRESSANTS: Antimony and its Salts; Veratrum Viride; Veratroidine and Jervine; Veratrum Album; Veratrine; Arnica Flowers and Arnica Root; Cytisine; Aconite; Aconitine; Hydrocyanic Acid; Silver Cyanide; Cyanogen; Tartaric Acid; Citric Acid; Lemon-Juice; Acetic Acid; Vinegar; Oxalic Acid.

ORDER III.—NUTRIANTS.

FAMILY I.—ASTRINGENTS: Tannic Acid; Gallic Acid; Galls; Catechu; Kino; Hamatoxylon; Rhatany; Oak Bark; Red and Pale Rose; Geranium; Glabra; Agaric; Alum; Aluminum Sulphate; Lead, its Salts and Preparations; Bismuth, its Salts and Preparations; Cerium Oxalate; Zinc, its Salts and Preparations; Cadmium; Copper, its Salts and Preparations; Silver, its Salts and Preparations.

FAMILY II.—TONICS: Iron, its Salts and Preparations; Manganese, its Salts and Preparations; Sulphuric Acid; Hydrochloric Acid; Nitric Acid; Nitro-Hydrochloric Acid; Lactic Acid; Phosphorus; Zinc Phosphide.

FAMILY III.—ALTERATIVES: Arsenic and its Preparations; Mercury, its Salts and Preparations; Iodine, its Salts and Preparations; Iodoform; Iodol; Cod-Liver Oil; Phosphoric Acid; Colchicum Seed and Colchicum Root; Sarsaparilla; Guaiac Wood and Guaiac Resin; Mezereum; Sassafra; Taraxacum; Ichthyol.

FAMILY IV.—ANTI-EPHODICS: Cinchona and its Alkaloids; Warburg's Tincture; Eucalyptus; Picric Acid.

FAMILY V.—ANTI-PYRETICS: Carbolic Acid; Creosote; Menthol; Thymol; Resorcin; Salicylic Acid; Oil of Gaultheria; Salicin; Salol; Bethol; Benzoic and Benzoic Acid; Antipyrin; Antifebrin; Phenacetin, or Acetphenetidin; Thallin; Kairin.

CLASS II.—LOCAL REMEDIES.

FAMILY I.—STOMACHICS: Quassia; Gentian; Nectandra; Columbo; Thoroughwort; Chirata; Wild-Cherry Bark; Cinnamon; Cloves; Nutmeg; Allspice; Cardamoms; Ginger; Black Pepper; Red Pepper; Oil of Cajuput; Oil of Sassafras; Orange Peel and Orange Flowers; Umbelliferous Aromatics; Chamomile; Serpentaria; Cascarella.

FAMILY II.—EMETICS: Ipecacuanha; Bloodroot; Apomorphine; Mustard; Mineral Emetics.

FAMILY III.—CATHARTICS: Tamarinds; Manna; Cassia Fistula; Cascara Sagrada; Wahoo; Magnesia; Sulphur; Sulphurated Potassa; Sulphurated Lime; Castor Oil; Mercurials; Rhubarb; Butternut; Aloes; Senna; Magnesium Sulphate; Solution of Magnesium Citrate; Granulated Magnesium Citrate; Sodium Sulphate; Sodium Phosphate; Rochelle Salt; Seidlitz Powder; Potassium Sulphate; Sodium Sulphovinate; Jalap; Colocynth; Scammony; Compound Cathartic Pills; May-Apple; Elaterium; Gamboge; Croton Oil.

FAMILY IV.—DIURETICS: Squill; Broom; Blatta; Sweet Spirit of Nitro; Caffeine; Potassium and its Salts; Lithium and its Salts; Piperazine; Strontium and its Salts; Buchu; Pareira; Uva Ura; Chimaphila; Juniper; Oil of Erigeron; Oil of Sandal-Wood; Stigmata of Zea Mays; Canada Turpentine; White Turpentine; Oil of Turpentine; Ohian Turpentine; Copaiba; Cubebs; Matico; Kawa; Cantharides.

FAMILY V.—DIAPHORETICS: Turkish Baths and Russian Baths; Dover's Powder; Jaborandi; Spirit of Mindererus; Sweet Spirit of Nitro; Alcohol.

FAMILY VI.—EXPECTORANTS: Atomization; Lobelia; Ipecacuanha; Tartar Emetic; Grindella; Ammonium Chloride; Senega; Ammoniac; Hydrogen Sulphide; Oil of Sandal-Wood; Balsam of Peru; Balsam of Tolu; Garlic; Squill; Tar; Eucalyptus; Terebene.

FAMILY VII.—EMMENAGOGUES: Myrrh; Aloes; Black Hellebore; Savine; Rue; Parsley; Apiol; Potassium Permanganate; Cantharides; Gusiak; Tanacetum; Pennyroyal.

FAMILY VIII.—OXYTOCICS: Ergot; Hydrastis; Hydrastine; Hydrastinine; Cotton-Root; Ustilago.

FAMILY IX.—SIALAGOGUES: Pellitory.

FAMILY X.—ERRHINES: Cubebs.

FAMILY XI.—EPISPASTICS: Cantharides.

FAMILY XII.—RUEFACIENTS: Mustard; Capsicum; Spices; Oil of Turpentine; Ammonia; Burgundy Pitch; Canada Pitch Plaster.

FAMILY XIII.—ESCHAROTICS: Caustic Potash; Vienna Paste; Arsenous Acid; Chloride of Zinc; Canquoin's Paste; Corrosive Sublimate; Solution of Mercuric Nitrate; Sulphuric Acid; Nitric Acid; Chromic Acid; Bromine; Zinc Sulphate; Copper Sulphate; Burnt Alum.

FAMILY XIV.—DEMULCENTS: Gum Arabic; Tragacanth; Slippery Elm; Iceland Moss; Carrageen; Liquorice Root; Flaxseed; Sassafras; Althaea; Tapioca; Arrow Root; Sage; Barley.

FAMILY XV.—EMOLLIENTS: Lard; Cacao Butter; Spermaceti; Lanolin; Glycerin; Saccharin; Cosmoline; Poultices.

FAMILY XVI.—DILUENTS: Water.

FAMILY XVII.—PROTECTIVES: Soap Plaster; Collodion; Solution of Gutta-Percha.

DIVISION II.—EXTRANEOUS REMEDIES.

FAMILY I.—ANTACIDS: Liquor Potasse; Sodium and its Salts; Lime, its Salts and Preparations; Chalk, or Calcium Carbonate.

FAMILY II.—ANTHELMINTICS: Pinkroot; Asedarach; Wormseed; Cusso; Santonica; Santonin; Male Fern; Pumpkin Seed; Turpentine; Pomegranate Root and its Alkaloids; Thymol; Cowhage; Kamala.

FAMILY III.—DIGESTANTS: Pepsin; Pancreatin; Extract of Malt; Papain.

FAMILY IV.—ABSORBENTS: Charcoal, Wood and Animal.

FAMILY V.—DISINFECTANTS: General Discussion: Use of Heat, Means of Disinfecting Apartments, etc.; Lead and Iron; Copperas; Lime; Corrosive Sublimates; Carbolic Acid; Cresol; Creolin; Lysol; Cresol Iodide; Cresol Salicylate; Potassium Permanganate; Chlorine; Chlorinated Lime; Labarraque's Solution; Boric Acid; Borax; Sulphurous Acid; Naphtalin; Naphtol; Hydrogen Dioxide.

APPENDIX.

Apothecaries' Measure; Metrical Weights and Measures; Relations of Apothecaries' and Metrical Weights and Measures—first, to each other, secondly, to Cubic Measure; Table of the Alcoholic Strength of Distilled Liquors, of Wines, and of Malt Liquors; Diagrams of Motor Points.

INDEX OF DISEASES.

- Abrasions :**
 solution of gutta-serena,
 933.
 collodion, 933.
- Abcesses :**
 boric acid, 974.
 hydrogen dioxide, 980.
 hydrogen peroxide, 980.
 tannic acid, 680.
 alcohol, 376.
 iodoforn, 595.
 menthol, 669.
 potassium permanganate, 969.
- Acidromatoposis :**
 metallo-therapy, 37.
- Acidity of stomach :**
 ammonia, 359.
 magnesia, 757.
- Acne :**
 arsenic, 557.
 ichthyol, 819.
 iodine, 586.
 phosphorus, 538.
 rosemary water, 724.
 solution of mercuric nitrate, 913.
- Acne rosacea :**
 oil of cajuput, 722.
- Acute poisoning :**
 alcohol, 376.

 Griffith's mixture, 532.
 iron, 521.
 saccharated ferrous carbonate, 522.
- Anæsthesia of skin :**
 electricity, 93.
 metallo-therapy, 37.
- Anæsthesia duodenale :**
 thymol, 931.
- Anæsthesia :**
 digitalis, 394.
 ergot, 879.
 potassium iodide, 588.
- Angina :**
 gum arabic, 916.
 carbolic acid, 660.
 potassium chlorate, 808.
- Angina pectoris :**
 amyl nitrite, 329.
 nitroglycerin, 333.
 potassium nitrite, 332.
 pyridin, 847.
 vapor of muriate of ammonia, (note) 849.
- Anorexia :**
 calumba, 716.
 quassia, 714.
 gentian, 714.
 chamomile, 724.
- Aortic disease :**
 digitalis, 392.
- Aphthous sore mouth :**
 potassium chlorate, 808.
 boric acid, 975.
 carbolic acid, 659.
- Apoplexy :**
 ergot, 880.
 emetics, 727.
- Arsenical poisoning :**
 antidote for, 522, 524.
 treatment of, 560.
- Arterial excitement :**
 aconite, 455.
 antimony, 428.
 veratrum viride, 424.
- Ascariæ :**
 anthelmintics, 942.
 oil of cajuput, 722.
 santonin, 947.
- Ascites :**
 elaterium, 780.
 cathartics, 753.
 jalap, 775.
- Asthenopia :**
 strychnine, 287.
- Asthma :**
 amyl nitrite, 329.
 antipyrin, 703.
 belladonna, 240.
 chloralamid, 204.
 emetics, 727.
 gelsemium, 338.
 hyosine hydrobromate, 190.

Asthma :

grindelia, 852.
 sparteine, 420.
 stramonium, 253.
 anaesthetics, 182.
 ether, 142.
 chloral, 199.
 lobelia, 335.
 nitroglycerin, 833.
 tobacco, 344.
 arsenic, 558.
 quebracho, 354.
 potassium iodide, 588.
 valerianate of amy, 333.
 vapor of muriate of ammonia, (note) 849.
 pyridin, 847.
 sulphuretted hydrogen, 857.

Ataxic pneumonia :

musk, 115.

Atheroma :

digitalis, 394.

Bed-sores :

chloral, 200.
 protectives, 932.

Belladonna-poisoning :

treatment of, 249.

Biliary calculi :

belladonna, 240.
 emetics, 727.
 valerianate of amy, 333.
 olive oil, 922.

Bilious fever :

blue mass, 763.
 quinine, 641.
 calomel, 763.
 jaborandi, 841.

Biliousness :

ammonium chloride, 747.
 blue mass, 763.
 ipecacuanha, 732.
 nitro-hydrochloric acid, 531.
 calomel, 763.
 emetics, 727.
 podophyllum, 778.
 potassium salts, 801.
 taraxacum, 618.

Bladder, irritable :

buchu, 813.
 hops, 126.
 pareira, 813.
 indian corn, 817.

Blennorrhagia :

iodol, 597.

Boils :

calcium sulphide, 759.
 cocaine, 269.
 phosphorus, 536.
 menthol, 669.
 sulphurated lime, 759.

Brain-softening :

phosphorus, 536.

Bright's disease :

antipyrin, 703.
 caffeine, 410.
 calomel, 792.
 cream of tartar, 802.
 diluents, 931.
 jaborandi, 841.

Bright's disease :

gallic acid, 481.
 potassium bitartrate, 802.
 potassium iodide, 589.
 sodium and theobromine salicylate, 793.
 strontium lactate, 812.
 strophanthus, 416.
 tincture of ferric chloride, 523.
 diuretics, 784.
 diaphoretics, 833.
 water, 784.

Bronchial secretion :

astringents, 849.

Bronchitis :

alum, 849.
 ammonium chloride, 864.
 opium, 172.
 alteratives, 850.
 antimony, 423.
 apomorphine hydrochlorate, 740.
 asafoetida, 118.
 astringents, 849.

Brown mixture, 918.

balsam of Tolu, 858.

benzoic acid, 692.

Calabar bean, 304.

cocaine, 269.

compound tincture of

benzoin, 693.

emetics, 728.

oil of amber, 124.

lobelia, 335.

oil of eucalyptus, 650.

oil of turpentine, 820.

naphtalin, 977.

tartar emetic, 428, 851.

ethyl nitrite, 331.

cimicifuga, 128.

sanguinaria, 735.

copaiba, 824.

cubeba, 826.

grindelia, 852.

inhalations, 849.

ipecacuanha, 851.

chloral, 191.

senega, 855.

alkalies, 846.

quebracho, 354.

ammoniac, 856.

garlic, 858.

squill, 859.

oil of sandal-wood, 816.

W&M.

strychnine, 286.

sulphuretted hydrogen,

857.

tar, 860.

terebene, 860.

Burgundy pitch, 908.

demulcents, 915.

liquorice, 918.

vapor of muriate of am-

monia, (note) 849.

Bronchorrhagia :

gallic acid, 481, 846.

alum, 485.

astringents, 849.

Bruises :

arnica, 446.
 camphor, 122.

Bruises :

ichthyol, 618.
 solution of lead subacetate, 498.

Buboes :

iodoform, 595.
 chloral, 200.
 carbolic acid injections, 500.

Burns :

boric acid, 974.
 Carron oil, 940.
 carbolic acid, 659.
 creosote, 667.
 ichthyol, 619.
 iodoform, 593.
 Kentish ointment, 908.
 lead carbonate, 499.
 resin cerate, 818.
 treatment of, (note) 598.
 chalk, 941.

Burns, inflamed :

carbolic acid injections, 660.

C.**Cachexia :**

glycerin, 926.

Calculi :

anaesthetics, 132.
 belladonna, 240.
 benzoic acid, 692.
 diluents, 931.
 piperazine, 810.
 water, 931.

Cancer :

arsenic, 911.
 Chian turpentine, 822.
 chloral, 199.
 cocaine, 269.
 conium, 350.
 escharotics, 909.
 iodoform, 593.
 solution of mercuric nitrate, 913.

Cancer of stomach :

extract of malt, 955.

Cancerum oris :

nitric acid, 529.

Carbuncle :

cocaine, 269.
 menthol, 669.

Carcinoma of stomach :

bismuth, 499.

Cardiac disease, chronic :

See HEART-DISEASE.

Cardiac dropsy :

caffeine, 394.
 calomel, 792.
 convallaria, 412.
 squill, 788.
 digitalis, 393, 789.
 adonidia, 420.
 ammonia, 358.
 sodium and theobromine salicylate, 793.
 sugar, 794.

Cardialgia :

antacids, 934.
 charcoal, 958.

Caries :

cod-liver oil, 602.
 cloves, 719.

Cataract :

phosphorus, 536.
atropine, 244.

Cataract :

ammonium chloride, 880.
camphoric acid, 123.
hydrastin, 889.
flaxseed, 918.
lead acetate, 649.
sulphuretted hydrogen,
857.

Cataract, chronic :

ammonium chloride, 884.
asafoetida, 118.
balsam of Peru, 858.
balsam of Tolu, 858.
benzoic acid, 692.

Cataract of bladder :

benzoic acid, 692.
juniper, 816.
grindelia, 852.
thymol, 669.
bethol, 691.
salol, 690.
naphthalol, 691.

Cataract, suffusion :

allium, R.V.
apomorphine, 739.
expectorants, 846.
garlic, 859.
emetics, 846.

Catarrhal jaundice :

blue mass, 763.
nitric acid, 473.
expectorants, 846.
surreal emenata, 759.
ipocacuanha, 733.
emetics, 727.
calomel, 763.
lemon juice, 473.
nitro-hydrochloric acid,
531.

sodium salts, 937.
potassium salts, 801.

Catarrhal pneumonia :

cod-liver oil, 601.
alteratives, 859.
iodine, 846.
sulphuretted hydrogen,
857.

Cerebral congestion :

cathartics, 753.
elaterium, 778.
ergot, 880.

Cerebral excitement :

cathartics, 742.
potassium bromide, 815.

Cerebral softening :

phosphorus, 536.
potassium bromide, 815.

Cerebritis :

electricity, 94.

Chancre :

iodoform, 593.
ascharotic, 909.
Canquoin's paste, 912.
hydrogen dioxide, 980.
hydrogen peroxide, 980.
solution of mercuric ni-
trate, 913.
corrosive sublimate, 913.
black and yellow washes,
579.

Chancre :

red mercuric oxide, 878.
resorcin, 673.
iodol, 597.
nitric acid, 529, 913.
yellow mercuric oxide,
578.

Chapped hands, lips, nipples :

benzoic acid, 692.
glycerin, 925.
solution of gutta-percha,
733.

Chloral poisoning :

treatment of, 202.

Chlorosis :

catarrh, 917.

Cholera :

ammonia, 338.
amyl nitrite, 330.
borax, (note) 976.
camphor, 127.
chloral, 199.
creolin, 956.
croscute, 647.
quinine, 640.
sulphuric acid, 526.
salol, 688.

Cholera infantum :

sulphuric acid, 526.
crocin, 947.
croscute, 667.
potassium chlorate, 866.
resorcin, 673.
saki, 69.

Cholera :

camphor, 132.
ipocacuanha, 733.

Chorde :

brominated camphor,
123.
hops, 126.
camphor, 122.
sulphonal, 209.

Chorea :

arsenic, 538.
Calabar bean, 304.
cimicifuga, 128.
chloral, 199.
coniun, 350.
antipyrin, 702.
bromide of iron, 525.
electricity, 97.
lobelia, 335.
sodium bromide, 319.
sulphonal, 209.
strychnine, 284.
zinc oxide, 503.

Chronic intestinal atony :

Calabar bean, 304.

Cirrhosis :

nitro-hydrochloric acid,
531.

Cold, a general :

Brown mixture, 916.
Dover's powder, 836.
hot baths, 830.
diaphoretics, 833.
alcohol, 845.
boneset, 716.
emetic, 728.
eupatorium, 716.

Cold, a general :

garlic, 858.
glycyrrhiza, 918.

Colic :

asafoetida, 118.
codeine, 183.
atropine, 240.
belladonna, 240.
cajuput, 722.
chloroform, 150.
ether, 142.
antacid, 934.
ginger, 720.
opium, 172.
amyl valerianate, 353.

Colica pictorum :

alum, 485.
atropine, 240.
sulphuric acid, 527.
belladonna, 240.
chloroform, 150.
Epsom salt, 771.

Colitis :

cold, 750.
chloral, 750.
forced emenata, 750.
magnesium sulphate,
771.
silver nitrate, 513.
sublimite of bismuth,
750.

Collapse :

ammonia, 358.
belladonna, 242.
caffeine, 410.
digitalis, 394.
epispastics, 895.
hont, 54.
mustard, 906.
strophanthus, 416.
Warburg's tincture, 647.

Colliquative sweats :

agaric, 484.
alum, 486.
camphoric acid, 123.
gallic acid, 481.
sulphuric acid, 526.
ergot, 879.
ipocacuanha, 733.
belladonna, 242.
sulphonal, 209.
tetronal, 210.
trional, 210.

Coma :

emetics, 727.

Condylomata :

nitric acid, 913.
chromic acid, 914.
carbolic acid, 659.

Congestion of brain :

elaterium, 778.
ergot, 880.

Congestion, hepatic :

nitro-hydrochloric acid,
531.

calomel, 763.
cathartics, 753.
emetics, 727.

nitric acid, 539.

Congestion of spinal cord :

ergot, 880.

Congestion, renal :

juniper, 816.

Conjunctivitis :

alum, 485.
citric ointment, 578.
copper sulphate, 505.
lithium carbonate, 809.
naphtol, 978.
silver nitrate, 511.
yellow mercuric oxide, 578.

Constipation :

aloes, 768.
alum, 485.
black draught, 770.
blue mass, 763.
calomel, 763.
compound cathartic pills, 777.
belladonna, 240.
diluents, 931.
Epsom salt, 771.
figs, 754.
fluid extract of rhamnus purshiana, 756.
strychnine, 286.
manna, 755.
general treatment, 749.
Calabar bean, 304.
cascara sagrada, 756.
castor oil, 760.
cathartics, 751.
podophyllum, 778.
magnesia, 757.
molasses, 754.
cracked wheat, 754.
bran, 754.
pills of aloes and asafetida, 769.
unbolted flour, 754.
Indian meal, 754.
forced enemata, 750.
rhubarb, 765.
solution of magnesium citrate, 772.
sulphur, 758.
tamarinds, 755.
gamboge, 782.
seidlitz powder, 773.
croton oil, 788.
wahoo, 756.

Contusions :

ichthyol, 619.

Convulsions :

anesthetics, 132.
amyl nitrite, 330.
asafetida, 118.
camphor, 122.
chloral, 199.
emetics, 727.
garlic, 859.
lobelia, 335.
musk, 115.
potassium bromide, 315.

Corpulence :

treatment of, 44.

Coryza :

amyl nitrite, 330.
bismuth, 499.
camphor menthol, (note) 669.
cocaine, 269.
oresol iodide, 868.
cubeb, 826, 895.
errhines, 895.

Coryza :

glycerin, 926.
ichthyol, 619.
iosophan, 968.
Cough, to quiet :
belladonna, 240.
prussic acid, 467.

Crampe :

sulphonal, 209.

Crampe of pregnancy :

chloral, 199.

Croup, membranous :

alum, 485, 741.
Coxe's hive syrup, 859.
emetics, 727.
glycerin, 926.
ipecacuanha, 732.
jaborandi, 842.
lime-water, 940.
mercury, 569.
yellow mercuric sub sulphate, 578.

Cuts :

solution of gutta-serena, 935.

Cystitis, ammoniacal :

benzoic acid, 692.
boric acid, 975.
crocin, 967.
hippurate of lime and lithia, (note) 690.

Cystitis, chronic :

arbutin, 815.
bethol, 689.
boric acid, 975.
buchu, 813.
camphoric acid, 122.
flaxseed, 918.
iodine, 586.
naphtol, 977.
pareira brava, 813.
uva ursi, 815.
turpentine, 821.
copaiba, 824.
cantharides, 828.
salicylic acid, 688.
resorcin, 673.
sea may, 817.

Cystorrhoea :

ergot, 681.

D.

Debility :

electricity, 97.
prunus Virginiana, 717.
cod-liver oil, 601.

Delirium of low fevers :

musk, 115.
valerian, 116.
opium, 172.
chloral, 197.
blisters, 899.

Delirium tremens :

digitalis, 394.
brominated camphor, 124.
veratrum viride, 436.
hops, 126.
hyosine hydrobromate, 190.
opium, 171.
chloral, 197.
croton oil, 783.

Delirium tremens :

potassium bromide, 315.
valerian, 116.

Dementia, senile :

potassium bromide, 315.

Depression :

treatment of, 40.

Dermal growths :

chromic acid, 914.
nitric acid, 913, 914.

Diabetes :

antipyrin, 703.
saccharin, 927.
opium, 172.
glycerin, 926.
jambul, 617.
lithium carbonate, 809.
piperasine, 810.
thymol, 670.
salol, 688.
ergot, 680.

Diabetes insipidus :

antipyrin, 703.
ergot, 680.
opium, 172.

Diarrhoea :

aromatics, 718.
tannic acid, 480.
calcium carbonate, 941.
Castillon's powder, 941.
catechu, 481.
coac, 279.
cold, 69.
croscote, 667.
antacids, 934.
haematoxylon, 481.
bismuth, 499.
bismuth and ammonium citrate, 502.
lead acetate, 496.
oil of caput, 722.
thymol, 671.
syrup of lime, 940.
ipecacuanha, 732.
jambul, 617.
sulphuric acid, 526.
magnesia, 757.
naphtol, 978.
nitrous acid, 530.
camphor, 122.
Hope's camphor mixture, 530.
opium, 172.
pepsin, 954.
resorcin, 678.
belladonna, 242.
sodium phosphate, 772.
strychnine, 286.
castor oil, 760.
rhubarb, 765.
rhatany, 482.
ergot, 879.
lime-water, 940.
carbolic acid, 669.
kino, 482.

Diarrhoea, chronic :

bismuth, 499.
bismuth and ammonium citrate, 502.
copper sulphate, 504.
ferrous sulphate, 522.
magnesia, 758.
copaiba, 824.

Diarrhoea, chronic :

- ergot, 879.
- nitro-hydrochloric acid, 51.
- sodium phosphate, 767.
- sine oxide, 503.
- sine sulphate, 503.

Digitalis-poisoning :

- treatment of, 396.

Dilatation of heart :

- digitalis, 391.
- convallaria, 412.

Dilatation of stomach :

- naphthol, 978.

Diphtheria :

- benzoic acid, 692.
- boric acid, 975.
- carbolic acid, 659.
- cold, 57.
- croscote, 667.
- hydrochloric acid, 528.
- hydrogen dioxide, 980.
- hydrogen peroxide, 980.
- resorcin, 673.
- jabonandi, 841.
- Monsel's solution, 623.
- papain, 956.
- potassium chlorate, 807.
- thymol, 671.
- tincture of ferric chloride, 523.
- lime water, 940.
- salicolic acid, 683.

Diphtheritic paralysis :

- electricity, 90.

Dilatation :

- anesthetics, 122.

Diuresis, excessive :

- turpentine, 821.

Dropsy :

- diaphoretics, 832.
- antihydropin, 793.
- lacta, 793.
- blatters, 899.
- caffeine, 394.
- camell, 791.
- cathartics, 753.
- convallaria, 412.
- copaiba, 424.
- digitalis, 393, 796.
- elaterium, 780.
- hot baths, 830.
- jabonandi, 841.
- jalap, 775.
- piperrazine, 816.
- potassium bitartrate, 802.
- scoparius, 791.
- senega, 555.
- sweet spirit of nitre, 793, 844.
- strophanthus, 416.
- squill, 758.
- veratrine, 444.

Drunkard's adynamia :

- capsicum, 721.

Dysentery :

- cathartics, 763.
- ochl, 70.
- creolin, 667.
- croscote, 667.
- lead acetate, 498.
- nitrous acid, 530.
- opium, 173, 177.

Dysentery :

- isoline, 586.
- ipomacumba, 732.
- calomel, 764.
- castor oil, 760.
- copaiba, 824.
- ergot, 879.
- naphthol, 978.
- potassium chlorate, 808.
- flaxseed, 918.
- glycerin, 926.
- forced enemas, 750.

Dysmenorrhoea :

- amyl nitrite, 336.
- aloes, 747.
- apiol, 864.
- antipyrin, 702.
- gossypii radicle cortex, 892.
- ginger, 720.
- hydrastinine hydrochlorate, 892.
- belladonna, 240.
- camphor, 121.
- guaiac, 865.
- cotton root, 825.
- solution of ammonium acetate, 843.

Dyspepsia :

- alcohol, 377.
- antacids, 934.
- charcoal, 958.
- calcium chloride, 941.
- ginger, 720.
- hydrastin, 889.
- hydrochloric acid, 528.
- malt, 954.
- pancreatin, 954.
- papain, 955.
- magnesia, 757.
- peppin, 954.
- pepper, 721.
- nitric acid, 530.
- naphthol, 978.
- assaftida, 118.
- silver nitrate, 512.
- sodium carbonate, 938.
- strychnine, 286.
- Calabar bean, 304.
- taraxacum, 618.
- terebene, 860.
- wahoo, 756.

Dyspepsia :

- Calabar bean, 304.
- quebracho, 354.
- strychnine, 286.

Dysuria :

- conium, 360.

E

Ecarache :

- brucine, 292.

Eczema :

- arsenic, 557.
- camphor menthol, (note) 669.
- menthol, 669.
- ichthyol, 619.
- glycerin, 925.
- naphthol, 978.
- sine oxide ointment, 503.
- papain, 950.
- resorcin, 673.

Effusion, pericardial :

- potassium iodide, 688.

Effusion, pleural :

- potassium iodide, 688.

Emphysema :

- quebracho, 354.
- strychnine, 286.

Empyema :

- oreocote, 667.
- iodine, 587.
- iodoforn, 695.

Endocarditis :

- mercury, 509.

Endometritis :

- hydrastinine hydrochlorate, 892.

Enteritis :

- alkali, 919.
- calomel, 764.
- magnesium sulphate, 771.
- opium, 172.
- silver nitrate, 512.
- chlorine, 969.
- castor oil, 760.
- flaxseed, 918.
- slippery elm, 916.

Enteritis, obstructive :

- calomel, 761.
- opium, 172.
- olnus fulva, 916.
- flaxseed, 918.

Ephemeral fever :

- aconite, 455.

Epididymitis :

- silver nitrate, 512.

Epilepsy :

- acetanilid, 708.
- ammonium bromide, 319.
- amyl nitrite, 329.
- antipyrin, 702.
- anesthetics, 122.
- boric acid, 975.
- bromide of gold, 321.
- bromide of camphor, 123.
- calcium bromide, 941.
- camphor, 122.
- emetica, 728.
- ergot, 880.
- Calabar bean, 304.
- hydrastinine hydrochlorate, 892.
- hydrobromic acid, 520.
- lithium bromide, 320.
- lobelia, 333.
- paraldehyde, 211.
- potassium bromide, 315.
- santonin, 947.
- silver nitrate, 512.
- sodium bromide, 319.
- strontium bromide, 512.
- sulphonal, 209.
- sine oxide, 503.

Epilepsia :

- tannic acid, 480.
- ergot, 678.

Epithelioma :

- resorcin, 673.
- papain, 946.

Erysipelas :

- benzole acid, 692.
- boric acid, 975.
- oreocote, 667.

Erysipelas :

ferrous sulphate, 522.
 ichthyol, 619.
 belladonna, 242.
 antipyrin, 702.
 pilocarpine, 841.
 quinine, 638.
 iodine, 586.
 carbolic acid injections,
 660.
 tincture of ferric chlo-
 ride, 523.
 silver nitrate, 511.

Exanthemata :

ammonia, 558.
 aconite, 455.

Exophthalmic goitre :

iodine, 586.
 ploric acid, 651.
 sparteine, 420.
 strophanthus, 416.

F.*Facial accumulation :*

black draught, 770.
 Epsom salt, 771.
 linseed oil, 922.

Failure of heart :

alcohol, 375.
 ammonia, 558.
 digitalis, 391.

Fatty heart :

amyl nitrite, 380.
 convallaria, 412.

Fauces, irritation of :

gum arabic, 916.

Fascitis :

silver nitrate, 511.

Favus :

naphtol, 978.

Feeble digestion :

feeding in, 20.

Fest, tender :

tannic acid, 480.

Felon :

carbolic acid, 660.
 cocaine, 269.
 silver nitrate, 512.

Fetid expectoration :

carbolic acid, 550.

Fever :

acetanilid, 708.
 antipyrin, 702.
 barley water, 920.
 kairin, 712.
 digitalis, 395.
 thallin, 711.
 aconite, 455.
 eold, 59.
 chloral, 199.
 gelsemium, 338.
 hydrochloric acid, 562.
 neutral mixture, 601.
 nitric acid, 530.
 phenacetin, 709.
 phenocoll, 711.
 ammonia, 558.
 salicylic acid, 682.
 tamarinde, 755.
 tartar emetic, 428.
 lemon-julea, 473.
 quinine, 638.

Fever :

diaphoretic, 833.
 jaborandi, 841.
 solution of potassium
 citrate, 801.

Fibroid tumors of uterus :

ergotin, 836.
 gossypil radicle cortex,
 892.

Fistula of anus :

belladonna, 241.
 benzoic acid, 692.
 cocaine, 268.

Fistula :

oreosote, 667.

Frost-bites :

ichthyol, 619.
 oreosote, 667.

Furuncles :

See BOILS.

G.*Galactorrhœa :*

ergot, 879.
 belladonna, 242.

Gall-stones :

sodium, 937.

Gangrene :

nitric acid, 529.
 carbolic acid, 659.

Gangrene, hospital :

bromine, 914.
 nitric acid, 529.

Gastralgia :

alum, 486.
 bismuth, 501.
 manganese, 526.
 prussic acid, 467.
 arsenic, 558.
 carbolic acid, 659.

Gastric catarrh :

ammonium chloride, 854.
 calcium chloride, 941.
 papain, 956.
 bismuth, 501.
 hydrastin, 838.

Gastric crisis :

antipyrin, 702.

Gastric ulcer :

oil of turpentine, 821.
 resorcin, 673.
 silver nitrate, 512.

Gastric uneasiness :

antacids, 934.

Gastritis :

silver nitrate, 512.
 veratrum viride, 435.

Gastro-enteritis :

chlorine water, 969.

Glands, enlarged :

ammoniac, 856.
 ammonium iodide, 590.
 carbolic acid injections,
 660.
 conium, 350.
 iodine, 587.
 iodoform, 595.
 mercury, 569.
 sulphurated lime, 750.
 cod-liver oil, 601.

Glaucoma :

atropine, 248.

Gleet :

thallin, 712.
 tincture of ferric chlo-
 ride, 523.
 turpentine, 821.
 cantharides, 828.

Goitre :

iodine, 586.

Gonorrhœa :

antimony, 428.
 arbutin, 815.
 diluents, 931.
 thallin, 712.
 benzoic acid, 692.
 bismuth, 499.
 creolin, 967.
 hydrogen dioxide, 980.
 hydrogen peroxide, 980.
 oil of sandal-wood, 817,
 858.
 oil of erigeron, 816.
 potassium bromide, 317.
 tartar emetic, 428.
 uva ursi, 814.
 pareira, 813.
 copaliba, 823.
 cubeba, 826.
 kava, 827.
 hydrastin, 838.
 smectic, 826.
 quinine, 642.
 resorcin, 673.
 silver nitrate, 511.
 sea mays, 817.
 zinc acetate, 504.

Gonorrhœal cystitis :

betbol, 689.

Gonorrhœal rheumatism :

salicylic acid, 688.

Gout :

arsenic, 558.
 cathartics, 753.
 salicylic acid, 688.
 ether, 142.
 ichthyol, 619.
 lithium carbonate, 809.
 magnesia, 757.
 cod-liver oil, 603.
 colchicum, 612.
 piperazine, 810.
 potassium iodide, 588.
 rubefacients, 905.
 strontium lactate, 812.
 sulphur, 758.
 sulphuretted hydrogen,
 657.

Gout, retrocedent :

ether, 142.

Granular conjunctivitis :

copper sulphate, 505.

Granulations, exuberant :

burnt alum, 914.
 copper sulphate, 914.
 zinc sulphate, 914.

Gravel :

diluents, 931.
 stigmata of Indian corn,
 817.
 water, 735.
 benzoic acid, 692.
 potassium salts, 801.

Graves's disease :

iodine, 586.

Gonorrœa's disease :
 sparteine, 420.
 strophanthus, 416.
Gumma's :
 calcium phosphate, 606.
Gums, retraction of :
 iodine, 587.

H. &

Hæmaturia :
 Monsel's solution, 523.
 tannic acid, 480.

Hæmaturia :
 gallic acid, 481.
 turpentine, 821.

Hæmoptysis :
 alum, 485.
 gallic acid, 481.
 ipæacuanha, 733.
 lead acetate, 498.
 Monsel's solution, 523.
 opium, 172.
 oil of turpentine, 821.
 astringent inhalations,
 810.
 ergot, 878.

Hands, disinfection of :
 creolin, 967.
 hydrogen dioxide, 980.
 hydrogen peroxide, 980.
 oxalic acid, 475.

Hay fever :
 cocaine, 269.
 quinine, 642.
 roscerin, 672.

Headache :
 ammonia, 358.
 antipyrin, 703.
 antacids, 935.
 caffeine, 409.
 ergot, 880.
 magnesia, 757.
 emetics, 727.
 nitroglycerin, 333.
 phenacetin, 708.
 valerianic acid, 117.

Heartburn :
 antacids, 934.

Heart-disease :
 acetonite, 435.
 adonidus, 421.
 amyl nitrite, 329.
 caffeine, 409.
 convallaria, 412.
 digitalis, 391.
 Hoffmann's anodyne,
 125.
 sparteine, 419.
 strophanthus, 416.
 veratrum viride, 435.

Heart-failure :
 alcohol, 375.
 ammonia, 358.
 amyl nitrite, 320.
 caffeine, 410.
 camphor, 122.
 digitalis, 391.
 nitroglycerin, 333.

Heart fever :
 antipyrin, 702.
 prunus Virginiana, 716.
 cold, 57.

Hemianæsthesia, 37.

Hemicrania :
 antipyrin, 703.

Hemiplegia :
 electricity, 90.
 strychnine, 285.
 massage, 25.

Hemorrhage from the bowels :
 cold, 68.
 ferrous sulphate, 522.
 tannic acid, 480.
 oil of turpentine, 821.

Hemorrhages :
 amyl nitrite, 330.
 astringents, 477.
 crocote, 667.
 hydrastinine hydrochlo-
 rate, 592.
 lead acetate, 498.
 Monsel's solution, 523.
 oil of ergeron, 816.
 oil of turpentine, 821.
 sulphuric acid, 527.
 malico, 826.
 ergot, 878.
 cocaine, 269.
 tannic acid, 480.

Hemorrhoids :
 cocaine, 269.
 enemata, 749.
 tannic acid, 480.
 stramonium, 253.
 glycerin, 926.
 iodoform, 595.
 potassium chlorate, 608.
 sulphur, 758.
 aloes, 768.
 cubeba, 826.
 tobacco, 344.
 ergotin, 881.

Hepatic abscess :
 ammonium chloride, 854.
 escharotics, 909.

Hepatic colic :
 amyl valerianate, 333.

Hepatic congestion :
 emetics, 727.
 nitric acid, 530.
 nitro-hydrochloric acid,
 531.

Hepatic torpor :
 ammonium chloride, 854.
 lemon juice, 472.
 chlorine, 969.
 sodium phosphate, 772.

Hepatic torpor :
 ammonium chloride, 854.
 lemon juice, 472.
 potash salts, 801.
 calomel, 761.
 escharotics, 753.
 diluents, 931.
 taraxacum, 618.
 sodium, 837.
 wahoo, 756.
 chirata, 716.

Hepatitis :
 ammonium chloride, 854.
 mercury, 569.
 nitro-hydrochloric acid,
 531.

Hernia :
 anæsthesia, 152.
 forced enemata, 760.

Herpes :
 naphthol, 978.

Hiccough :
 belladonna, 240.
 chloral, 199.
 ether, 142.
 musk, 115.
 oil of amber, 124.
 sulphonal, 209.

Hoarseness :
 cubeba, 694.

Hospital gangrene :
 bromine, 914.
 nitric acid, 529.

Hydrocele :
 iodine, 587.
 carbolic acid, 660.

Hydrocephalus :
 iodoform, 593.
 potassium iodide, 668.

Hydrophobia :
 escharotics, 909.
 caustic potash, 916.
 potassium chlorate, 807.

Hypæmia, pulmonary :
 ergot, 880.

Hypæsthesia :
 electricity in, 93.
 acouite, 456.

Hypæremia :
 treatment, 728.

Hypæpyrexia :
 quinine, 638.
 salicylic acid, 682.

Hypertrophy of heart :
 acouite, 455.
 digitalis, 391.
 veratrum viride, 435.

Hypertrophy of uterus :
 ergot, 880.

Hypochondriasis :
 alcohol, 376.
 codeine, 184.
 electricity, 97.

Hysteria :
 antipyrin, 702.
 antispasmodics, 112.
 brominated camphor,
 124.
 cocaine, 260.
 crocote, 667.
 gold and sodium chloride,
 579.
 sparteine, 419.
 musk, 115.
 potassium bromide, 316.
 valerian, 118.
 valerianic acid, 117.
 asafetida, 118.
 camphor, 122.
 conium, 350.
 electricity, 97.
 anæsthetics, 112.
 ether, 142.
 oil of wormseed, 944.
 oil of amber, 124.
 pills of aloes and asafet-
 ida, 760.
 sodium bromide, 319.
 valerianate of ammo-
 nium, 117.
 valerianate of amyl,
 335.

Hysterical convulsions :

anæsthesia, 132.
antipyrin, 702.
potassium bromide, 315.
camphor, 122.

Hysterical paralysis :

electricity, 90.

L.

Ichthyosis :

naphthol, 978.

Impotence :

turpentine, 321.

Incontinence of urine :

antipyrin, 703.
belladonna, 240.
bromide of iron, 325.
chloral, 199.
strychnine, 286.
turpentine, 321.

Indurated glands :

iodine, 587.
mercurial ointment, 574.
mercurial plaster, 574.

Infantile colic :

assafetida, 118.

Infantile convulsions :

anæsthetics, 132.
assafetida, 118.
brominated camphor, 124.

chloral, 199.
oil of amber, 124.
garlic, 859.
potassium bromide, 315.

Infantile diarrhoea :

antipyrin, 703.
sodium phosphate, 747.
thymol, 671.

Infantile paralysis :

electricity, 90.
massage, 25.
strychnine, 286.

Inflammations :

borax, 975.
cold, 56.
lead acetate, 498.
blisters, 899.
tartar emetic, 428.
mercury, 568.
carbolic acid, 660.
stramonium, 253.
copaiba, 823.
silver nitrate, 512.
solution of lead subacetate, 498.
terebene, 860.

Inflammatory fever :

tartar emetic, 428, 834.

Influenza :

naphthol, 979.

Insanity :

hyosine hydrobromate, 190.
hyoscyamus, 254.
potassium bromide, 315.

Intermittent fever :

amyl nitrite, 330.
ammonium chloride, 854.
arsenic, 555.
apiol, 854.
chloroform, 150.
diaphoretic, 833.

Intermittent fever :

eucalyptus, 649.
gelsemium, 338.
ipeacacanha, 733.
hot baths, 850.
piperin, 721.
quinine, 640.
salicylic acid, 682.

Intertrigo :

chalk, 941.
ichthylol, 619.

Intestinal atony :

Calabar bean, 304.

Intestinal catarrh :

ammonium chloride, 854.
hydrastis, 884.
eucalyptus, 649.
forced enemata, 750.
Calabar bean, 304.
naphthalin, 977.
thymol, 671.

Intestinal dyspepsia :

Calabar bean, 304.
hydrochloric acid, 528.

Intestines, inflammation of :

slippery elm, 918.
cathartics, 753.
naphthalin, 977.

Intussusception :

forced enemata, 750.

Iritis :

atropine, 247.
mercury, 569.

Irritable bladder :

hops, 126.
buchu, 813.
pareira brava, 812.

Irritable heart :

digitalis, 393.
sparteine, 419.

Irritative fevers :

aconite, 455.

Itch :

glycerin, 925.
sulphur, 758.

J.

Jaundice :

blue mass, 763.
citric acid, 473.
emetics, 727.
forced enemata, 750.
lemon-juice, 473.
nitro-hydrochloric acid, 531.
potassium salts, 801.
calomel, 763.
ipeacacanha, 733.

Joints, chronic inflammation of :

blisters, 899.
cod-liver oil, 602.
gold and sodium chloride, 650.
mercurial plaster, 574.

Joints, enlarged :

ammoniac plaster with mercury, 554.
sonium, 350.
iodine, 586.
cod-liver oil, 602.

Joints, tuberculosis of :

iodoform, 595.

K.

Keloid :

ichthylol, 619.

Keratitis :

atropine, 247.

Kidneys, congestion of :

gin, 816.
flaxseed, 918.

L.

Labor :

anæsthesia, 131.
antipyrin, 703.
creolin, 987.
ergot, 876.
quinine, 631.

Laryngismus stridulus :

antipyrin, 703.
belladonna, 240.
chloral, 199.

Laryngitis :

ammonium chloride, 850.
camphor-menthol, (note) 669.
cocaine, 269.
diluenta, 849.
gelsemium, 338.
glycerin, 925.
iodol, 598.
naphthol, 978.
narcotics, 850.
mercury, 569.
inhalations, 848.
silver nitrate, 511.

Lead paralysis :

strychnine, 285.
electricity, 90.

Lead-poisoning :

atropine, 240.
alum, 488.
sulphuric acid, 528.
treatment of, 494.
strychnine, 285.

Lepra :

ichthylol, 619.
ammonium iodide, 600.

Leucorrhœa :

bismuth, 499.
crocoate, 667.
tannic acid, 486.
ferrie ammonium sulphate, 525.
iodine, 586.
potassium permanganate, 968.
resorcin, 673.

Leukæmia :

ergot, 879.
cold, 55.
iodoform, 593.

Lichen :

arsenic, 557.

Lipoma :

ichthylol, 619.

Lithæmia :

sodium phosphate, 772.

Lober pneumonia :

quinine, 638.

Locomotor ataxia :

antipyrin, 703.
silver nitrate, 513.

Locomotor ataxia, pains of:
acetanilid, 708.
antipyrin, 703.
phenacetin, 709.
sodium phosphate, (note)
773.

Lumbago:
cod liver oil, 603.
ichthyol, 619.
potassium iodide, 588.
sulphur, 758.

Lumbrici:
See Rot su-worms.

Lepus:
arsenic, 911.
arsenic iodide, 563.
cantharidin, 902.
ichthyol, 619.
guaiacol, 663.
phosphorus, 536.
potassium cantharidin-
ate, (note) 903.
red mercuric iodide,
578.
aristol, 597.

Lymphadenitis:
ichthyol, 619.
sulphurated lime, 759.

Lymphoma:
arsenic, 556.

M.

Material neuralgia:
quinin, 641.
arsenic, 556.

Malarial poisoning:
ammonium chloride, 854.
betanaine, 715.
blue mass, 763.
chloroform, 150.
cinchonine, 645.
calomel, 763.
gelsemium, 338.
quinine, 640.
arsenic, 556.
emetics, 728.
equisetum, 896.
nectandra, 715.
potassium salts, 801.
apiol, 864.
ergot, 881.
eucalyptus, 649.
jaborandi, 841.
salicylic acid, 682.
picric acid, 681.
Warburg's tincture, 647.

Malignant pustule:
escharotics, 909.

Mania:
belladonna, 242.
cathartics, 753.
chloral, 197.
croton oil, 763.
gelsemium, 339.
opium, 350.
blisters, 899.
hyoscyne hydrobromate,
190.
potassium bromide, 315.

Mastitis:
belladonna, 245.

Melancholia:
alcohol, 376.
cocaine, 260.

Meningitis:
cold, 57.

Menopausal symptoms:
potassium bromide,
317.

Menorrhagia:
aloes, 760.
oil of erigeron, 816.
croton, 667.
hydrastinine hydrochlo-
rate, 892.
ruc, 863.
savin, 863.
ergot, 878.
phosphate of calcium,
896.
digitalis, 396.
solution of ammonium
acetate, 843.

*Menstruation, acute suppres-
sion of:*
Dover's powder, 834.
ginger, 720.
alcohol, 845.
diaphoretic, 832.
hot baths, 830.

Mercurial sore mouth:
tannic acid, 489.
opium, 172.
belladonna, 242.

Metallic poisoning:
potassium iodide, 588.

Metricia:
croton, 667.
ergot, 881.

Metrorrhagia:
hydrastinine hydrochlo-
rate, 892.
ergot, 878.

Migraine:
aconite, 456.
ammonium chloride,
854.
amyl nitrite, 329.
antipyrin, 703.
bromide of gold, 321.
cannabis indica, 219.
cocaine, 270.
caffeine, 409.

Mitral disease:
digitalis, 392.

Multiple sclerosis:
acetanilid, 708.

Muscarine poisoning:
digitalis, 395.

Mucular rheumatism:
opium, 172.
jaborandi, 841.
eupatorium, 716.
aconite, 455.
Dover's powder, 836.
sulphur, 758.
ichthyol, 619.
potassium iodide, 588.
diaphoretic, 832.
salicylic acid, 683.

Myelitis:
electricity, 89.
phosphorus, 536.
silver nitrate, 513.

N.

Narcotic poisoning:
oponophine hydrochlo-
rate, 739.
emetics, 726.
ipococoumba, 732.
mustard, 740.
zinc sulphate, 741.

Nasal catarrh:
hydrastin, 889.
eucalyptus, 650.

Necrosis:
carbolic acid, 659.

Nephritis:
belladonna, 241.
caffeine, 410.
calomel, 762.
jaborandi, 841.
potassium bitartrate, 802.
sodium and theobromine
salicylate, 793.
stroblum lactate, 612.

Nervous collapse:
mustard, 740.

Nervous cough:
belladonna, 240.
flaxseed, 918.
gelsemium, 338.

Nervous excitement:
camphor, 121.
potassium bromide, 315.

Nervous exhaustion:
electricity, 97.
phosphorus, 536.
Warburg's tincture, 647.

Nervous headache:
caffeine, 409.
camphor, 121.
ether, 142.
valerianate of ammo-
nium, 117.
valerianic acid, 117.

Nervous irritability:
assaftida, 118.
camphor, 121.
potassium bromide, 315.
prussic acid, 467.
valerian, 116.

Nervous vomiting:
hydrocyanic acid, 467.
carbolic acid, 659.

Neuralgia:
ammonium chloride, 855.
arsenic, 558.
antipyrin, 703.
blisters, 899.
electricity, 93.
gold and sodium chloride,
580.
phosphorus, 536.
potassium bromide, 315.
veratrine, 444.
aconite, 456.
alcohol, 376.
valerianic acid, 117.
gelsemium, 339.
cannabis indica, 219.
belladonna, 241.
ether, 142.
chloral camphor, 206.
chloroform, 150.
croton chloral, 206.

- Neuralgia :**
 nitroglycerin, 333.
 iodoform, 592.
 cod-liver oil, 603.
 conium, 350.
 potassium iodide, 588.
 valerianate of ammonium, 117.
 quinine, 641.
 epispastics, 899.
- Neuralgia, intermittent :**
 apiol, 664.
 aromatics, 719.
 arsenic, 538.
 ergot, 880.
 oil of peppermint, 718.
 phenacetin, 709.
 quinine, 641.
- Neuralgia, intestinal :**
 alum, 485.
- Neuralgia, rheumatic :**
 aconite, 455.
 electricity, 93.
 potassium iodide, 588.
 veratrine, 444.
- Neurasthenia :**
 cocaine, 260.
 gold and sodium chloride, 580.
 sodium phosphate, (note) 773.
 sparteine, 419.
- Neuritis :**
 blisters, 899.
- Night-pains, syphilitic :**
 iodoform, 592.
- Night-sweats :**
 agaric, 484.
 alum, 485.
 belladonna, 242.
 camphoric acid, 123.
 ergot, 879.
 gallic acid, 481.
 sulphonal, 209.
 sulphuric acid, 528.
 tetronal, 210.
 trional, 210.
 ipecacuanha, 733.
- Nipples, sore :**
 tannic acid, 430.
- Nocturnal cramps :**
 sulphonal, 209.
- Nodes :**
 ammoniac, 856.
- Nymphomania :**
 hyoscin hydrobromate, 190.
 potassium bromide, 317.
- O.
- Obesity :**
 saccharin, 927.
 treatment of, 44.
- Obstruction of the bowels :**
 belladonna, 241.
 opium, 172.
- Oedema of the lungs :**
 jaborandi, 841.
- Oesophagus, stricture of :**
 anaesthetics, 132.
- Onychia maligna :**
 corrosive sublimate, 913.
 lead nitrate, 499.
- Ophthalmia :**
 atropine, 247.
 iodine, 586.
- Opium habit :**
 cocaine, 260.
- Opium-poisoning :**
 caffeine, 409.
 atropine, 242.
 treatment of, 173.
- Osmidrosis :**
 tannic acid, 430.
- Osteomalacia :**
 phosphorus, 536.
 phosphate of calcium, 605.
- Otitis :**
 naphthol, 978.
 resorcin, 673.
- Otorrhoea :**
 creosote, 667.
 hydrastin, 889.
 potassiumpermanganate, 908.
- Ovarian neuralgia :**
 ammonium chloride, 854.
 gelsemium, 339.
 gold and sodium chloride, 580.
- Over-secretion :**
 astringents, 477.
- Oxalic acid diathesis :**
 nitric acid, 530.
 nitro-hydrochloric acid, 522.
- Oxyuris vermicularis :**
 forced enemata, 750.
- Oxuna :**
 iodine, 586.
 potassium permanganate, 908.
- P.
- Pain :**
 acetanilid, 708.
 anaesthetics, 131.
 antipyrin, 703.
 cannabis Indica, 219.
 chloral, 199.
 exalgine, (note) 704.
 oil of caput, 722.
 opium, 171.
 phenacetin, 709.
 phenocell, 711.
- Palpitation of heart :**
 belladonna, 245.
 convallaria, 412.
 sparteine, 419.
- Papilloma :**
 resorcin, 673.
- Paralysis :**
 electricity, 90.
 massage, 25.
 strychnine, 285.
- Paralysis agitans :**
 conium, 350.
 hyoscin hydrobromate, 190.
 sodium phosphate, (note) 773.
- Paraplegia, myelitic :**
 silver nitrate, 513.
 phosphorus, 536.
- Parasitic skin-diseases :**
 iodine, 586.
 oil of caput, 722.
- Parturition :**
 anaesthetics, 131.
 antipyrin, 702.
- Pemphigus :**
 arsenic, 537.
- Pericardial effusions :**
 iodoform, 593.
 blisters, 899.
 potassium iodide, 588.
 squill, 786.
- Pericarditis :**
 mercury, 569.
 iodoform, 593.
 potassium iodide, 588.
- Periostitis, syphilitic :**
 phosphate of calcium, 605.
- Peripheral palsies :**
 electricity, 92.
- Peritonitis :**
 cold, 57.
 veratrum viride, 435.
 aconite, 455.
 opium, 172.
 mercury, 569.
 blisters, 899.
 iodoform, 593.
 ipecacuanha, 634.
 poultices, 929.
- Pernicious fever :**
 ammonia, 358.
 epispastics, 899.
 mustard, 740.
 quinine, 640.
- Phagedenic chancres :**
 nitric acid, 529, 918.
- Phantom tumor :**
 Calabar bean, 304.
- Phlegmons :**
 carbolic acid injections, 560.
- Phosphatic gravel :**
 sea mays, 817.
 benzoic acid, 692.
- Phosphorus-poisoning :**
 treatment of, 643.
- Phthisis :**
 ammonium iodide, 590.
 codeine, 184.
 alcohol, 377.
 alteratives, 850.
 cannabis Indica, 219.
 cantharidin, 902.
 cod-liver oil, 601.
 conium, 350.
 cocaine, 269.
 creosote, 666.
 eucalyptus, 650.
 gallic acid, 481.
 guaiscol, 668.
 iodine, 586.
 morrhual, (note) 661.
 narcotics, 850.
 phosphate of calcium, 605.
 prunus Virginiana, 717.
 resorcin, 673.
 sulphuretted hydrogen, 657.
 strychnine, 286.

Pâthosis :
thymol, 671.

Ptyriasis :
oil of cajuput, 722.

Pleurisy :
cold, 57.
gelsemium, 338.
mercury, 569.
jaborandi, 841.
iodine, 587.
iodoform, 593.
blisters, 599.
belladonna, 242.
oil of turpentine, 820.
potassium iodide, 588.
poultices, 929.
salicylic acid, 683.

Pleuritic effusion :
antipyrin, 703.
blisters, 599.
equil, 788.
salicylic acid, 683.
sugar, 794.

Pneumonia :
aconite, 455.
alcohol, 376.
alteratives, 850.
antipyrin, 702.
ammonia, 358.
ammonium carbonate, 360.
belladonna, 241.
cold, 57.
ergot, 840.
expectorants, 846.
gelsemium, 338.
guaiacol, 668.
digitalis, 393.
naphthol, 978.
oil of turpentine, 821.
tartar emetic, 423.
musk, 115.
chloral, 199.
mercury, 569.
phosphorus, 536.
quabrincho, 354.
quinine, 638.
blisters, 599.
poultices, 929.
veratrum viride, 435.
strychnine, 286.

Poisoning :
digitalis, 393.
ammonia, 358.
alcohol, 376.
heat, 55.

Poisonous fungi :
atropine, 745.

Post-partum hemorrhage :
anesthesia, 132.
ergot, 878.
ippecacuanha, 733.
quinine, 632.

Pregnancy :
confection of senna, 770.
ippecacuanha, 732.
phosphate of calcium, 606.

Priapism :
bops, 128.

Prolapse of rectum :
strychnine, 286.

Prurigo :
hydrocyanic acid, 467.
naphthol, 978.

Pruritus :
brucina, 292.
chloral camphor, 205.
glycerin, 925.
tobacco, 344.
menthol, 669.

Pseudo-membranous croup :
alum, 455, 741.
ippecacuanha, 732.
mercury, 569.
lime-water, 940.

Psoriasis :
ammonium iodide, 590.
goa powder, (note) 765.
resorcin, 673.
oil of cajuput, 722.
phosphorus, 536.
chrysophanic acid, 765.
arsenic, 557.
iodine, 586.
glycerin, 925.
aristol, 597.

Psorophthalmia :
oil of turpentine, 821.

Ptyalism :
belladonna, 242.
opium, 173.

Puerperal convulsions :
amyl nitrite, 330.
anesthetics, 132.
camphor, 122.
chloral, 199.
nitroglycerin, 333.

Puerperal eclampsia :
anesthetics, 132.
urethan, 213.
nitroglycerin, 333.

Puerperal fever :
boric acid, 975.
oil of turpentine, 821.
digitalis, 396.

Puerperal peritonitis :
mercury, 569.

Pulmonary edema :
strophanthus, 416.
jaborandi, 841.

Purpura hemorrhagica :
oil of turpentine, 821.
ergot, 878.

Pyemia :
alcohol, 376.
quinine, 636.
tincture of ferri chloride, 523.

Pyelitis, chronic :
buchu, 813.
ura ursi, 814.
juniper, 816.
turpentine, 821.
arbutin, 814.
copaiba, 824.
cantharides, 828.
salicylic acid, 683.

Pyogenic membranes :
papain, 956.

Pyrexia :
acetanilid, 708.
cold, 58.
chloral, 199.
antipyrin, 702.

Pyrexia :
hairin, 712.
phenacetin, 709.
resorcin, 673.
thymol, 689.
salicylic acid, 683.
thallin, 711.

Pyrosis :
bismuth, 499.
manganese, 536.
silver nitrate, 512.
silver oxide, 515.

R.

Rachitis :
phosphorus, 536.
phosphate of calcium, 605.

Reaction of degeneration, 88.

Rectum :
feeding by, 35.

Relaxation :
tannic acid, 480.
atringenta, 477.
strychnine, 284.

Relaxation of uvula :
pellitory, 894.

Remittent fever :
diaphoretics, 833.
quinine, 641.
arsenic, 555.
ippecacuanha, 733.
Warburg's tincture, 647.

Renal calculi :
belladonna, 240.
piperazine, 810.

Renal colic :
valerianate of amyl, 333.

Rest-cure, 40.

Retention of urine :
strychnine, 286.

Retraction of gums :
iodine, 587.

Rheumatic hyperpyrexia :
quinine, 638.
salicylic acid, 683.

Rheumatic neuralgia :
electricity, 93.
aconite, 455.
potassium iodide, 588.

Rheumatism :
aconite, 455.
alcohol, 845.
ammonium bromide, 319.
ammonium iodide, 590.
antipyrin, 702.
arsenic, 558.
bethol, 689.
Burgundy pitch, 908.
diaphoretics, 832.
jaborandi, 841.
cathartics, 753.
conium, 350.
ichthyol, 619.
carbolic acid injections, 660.
chloroform, 150.
oil of amber, 124.
oil of cajuput, 722.
oil of gaultheria, 656.
oil of peppermint, 718.
veratrine, 444.

Rheumatism :

iodine, 586.
 iodoform, 592.
 cod-liver oil, 603.
 Donovan's solution, 589.
 Dover's powder, 834.
 colchicum, 612.
 gold and sodium chloride, 580.
 guaiac, 617.
 opium, 171.
 magnesia, 757.
 mercury, 569.
 pellitory, 894.
 phenocoll, 710.
 potassium iodide, 588.
 potassium acetate, 801.
 quinine, 638.
 salicin, 687.
 salicylic acid, 682.
 Soudamora's mixture, 613.
 strontium lactate, 812.
 sulphur, 758.
 sulphurated potassa, 758.
 vinegar, 473.

Rheumatism, inflammatory :

ammonium bromide, 319.
 quinine, 638.
 lemon-juice, 473.
 cimicifuga, 123.
 benzoic acid, 692.
 phenocoll, 710.
 potassium iodide, 588.
 potassium salts, 801.
 salol, 687.
 salicin, 686.
 salicylic acid, 683.
 oil of gaultheria, 686.
 Dover's powder, 835.
 potassium acetate, 801.
 potassium nitrate, 805.

Rheumatism, erythritic :

red mercury iodide, 578.

Rheumatoid arthritis :

arsenic, 558.
 ichthyol, 619.
 potassium iodide, 588.
 salicylic acid, 683.

Rhus toxicodendron poisoning :

lobelia, 335.

Rickets :

phosphorus, 536.
 cod-liver oil, 603.

Rigidity of os uteri :

belladonna, 240.

Round-worms :

anthelmintics, 942.
 cowhage, 951.
 oil of turpentine, 950.
 spigelia, 942.
 asedarach, 943.
 chenopodium, 944.
 santonin, 947.

Scabies :

crocoll, 967.
 glycerin, 925.
 sulphur, 758.

Scarlet fever :

aconite, 455.

Scarlet fever :

antipyrin, 702.
 belladonna, 242, 249.
 cold, 69.
 hydrogen dioxide, 969.
 hydrogen peroxide, 980.
 potassium chlorate, 897.
 quinine, 638.

Sciatica :

castum, 340.
 cod-liver oil, 603.
 sulphur, 758.
 electricity, 93.
 guaiac, 617.
 potassium iodide, 589.

Sclerosis :

acetasilid, 708.
 gold and sodium chloride, 580.

Scrofulous :

alcohol, 377.
 ammonium iodide, 590.
 sarsaparilla, 616.
 gold and sodium chloride, 580.
 pipalmewa, 616.
 iodide of gold, 580.
 iodine, 586.
 iodol, 597.
 cod-liver oil, 601.
 oxide of gold, 580.
 phosphate of calcium, 605.
 phosphoric acid, 604.
 syrup of ferrous iodide, 524.

Scrofulous tumors :

ammoniac plaster with mercury, 866.

Scrofulous ulcers :

sulphurated lime, 759.

Scurvy :

lemon-juice, 472.
 potassium chlorate, 807.

Seat-worms :

anthelmintics, 942.
 forced enemata, 750.
 naphthalin, 977.
 quassia, 714.
 oil of cajuput, 722.
 vinegar, 473.

Seborrhoea :

glycerin, 925.

Seminal emissions :

antipyrin, 703.
 hyosine hydrobromate, 190.

Septicæmia :

boric acid, 975.
 quinine, 636.

Serous diarrhoea :

cold, 69.
 sulphuric acid, 526.
 nitrous acid, 530.
 oil of cajuput, 722.

Sexual excitement :

camphor, 122.
 hops, 126.
 hyosine hydrobromate, 190.
 potassium bromide, 817.

Shock :

belladonna, 242.

Shock :

epispastica, 898.
 ergot, 889.
 hot baths, 56.

Sick headache :

antacids, 936.
 magnesia, 757.

Sick stomach :

ipeacasuanha, 732.
 effereasing draught, 801.
 potassium citrate, 801.

Sinking-opelle :

ether, 142.

Skin, affections of :

ammoniated mercury, 879.
 arsenic, 556.
 chalk, 941.
 citrine ointment, 578.
 cod-liver oil, 603.
 Donovan's solution, 589.
 goe powder, (note) 765.
 ichthyol, 619.
 iodide of gold, 580.
 magnesia, 757.
 nitro-hydrochloric acid, 532.
 oxide of gold, 580.
 tar, 860.
 oopalba, 824.
 sulphur, 758.
 sulphurated potassa, 758.
 sulphuretted hydrogen, 557.
 zinc oxide, 503.

Sleeplessness :

opium, 171.
 eannabis Indica, 219.
 chloral, 197.
 hyosine hydrobromate, 190.
 acetophenone, 213.
 potassium bromide, 315.
 amylene hydrate, 212.
 urethan, 212.
 hypona, 213.
 trional, 210.
 tetronal, 210.

Smallpox :

opium, 172.
 ichthyol, 619.

Snake-poisoning :

ammonia, 358.
 alcohol, 376.
 epispastica, 899.

Softening of brain :

phosphorus, 536.

Sore throat :

alum, 485.
 chlorine-water, 969.
 creosote, 667.
 belladonna, 241.
 potassium chlorate, 898.
 silver nitrate, 511.
 sumach berries, 484.
 gum arabic, 916.
 carbolic acid, 659.
 tannic acid, 480.
 tincture of ferrie chlor-
 ride, 523.
 vapor of muriste of am-
 monia, (note) 849.

- Spasms :**
 atropine, 240.
 tobacco, 344.
 opium, 171.
 asafetida, 118.
 emetics, 727.
 hyoscyne hydrobromate, 190.
 oil of cajuput, 723.
 aconite, 456.
 belladonna, 240.
 chloral, 197.
 anæsthetics, 131.
 lobelia, 335.
 opium, 171.
 sulphonal, 209.
- Spermatorrhœa :**
 brominated camphor, 123.
 digitalis, 394.
 chloral, 199.
 hyoscyne hydrobromate, 190.
 sulphonal, 209.
 turpentine, 321.
- Spirital accessory epæm :**
 hyoscyne hydrobromate, 190.
 paraldehyde, 211.
- Spirital anæmia or irritation :**
 electricity, 96.
- Spirital congestion :**
 electricity, 96.
 ergot, 840.
- Spirital constriction :**
 anæsthesia, 132.
- Spirital depression :**
 strychnine, 285.
- Spirital inflammation, 96.**
- Splices, enlargement of :**
 cold, 57.
 ergot, 879.
 potassium bromide, 317.
- Spongy juncs :**
 tannic acid, 430.
- Sprains :**
 arnica, 446.
 camphor, 122.
 dilute acetic acid, 473.
 Goulard's extract, 498.
 ichthyol, 619.
 massage, 35.
 vinegar, 473.
- Spasmodic epileptics :**
 amyli nitrite, 329.
- Stomatitis :**
 carbolic acid, 659.
 potassium chlorate, 808.
 sodium chlorate, (note) 808.
- Strangury :**
 opium, 177.
- Stricture, spasmodic :**
 anæsthetics, 132.
 belladonna, 240.
- Strychnine-poisoning :**
 treatment of, 289.
 amyli nitrite, 330.
 Calabar bean, 304.
 camphor, 122.
 chloral, 290.
 potassium bromide, 316.
 tobacco, 344.
- Subinvolution of uterus :**
 ergot, 881.
- Suffocative catarrh :**
 apomorphine hydrochlorate, 739.
 emetics, 846.
 garlic, 839.
 treatment of, 846.
- Sunburn :**
 dilute acetic acid, 473.
 vinegar, 473.
- Suppressed menstruation :**
 ginger, 720.
 diaphoretic, 832.
 Dover's powder, 824.
 alcohol, 845.
- Suppression of urine :**
 digitalis, 730.
- Sweating, excessive :**
 gallic acid, 480.
 chalk, 941.
 jaborandi, 841.
 sulphuric acid, 527.
 tannic acid, 480.
- Syncope :**
 alcohol, 375.
 ammonia, 358.
 amyli nitrite, 329.
 digitalis, 394.
 ether, 142.
- Synovitis, chronic :**
 carbolic acid injections, 660.
- Syphilis :**
 ammonium iodide, 590.
 aristol, 597.
 gold and sodium chloride, 580.
 iodide of gold, 580.
 nitro-hydrochloric acid, 532.
 iodol, 597.
 mercury, 570.
 nitric acid, 530.
 iodoform, 593.
 phosphate of calcium, 606.
 oxide of gold, 580.
 potassium iodide, 588.
 sulphur, 758.
 cod-liver oil, 603.
 red mercuric iodide, 578.
 sarsaparilla, 616.
 guaiac, 616.
 potassium chlorate, 607.
 yellow mercurous iodide, 578.
- Syphilitic nodes :**
 ammoniac plaster with mercury, 656.
- T.**
- Tubercle mesenterica :**
 cod-liver oil, 602.
- Tape-worm :**
 anthelmintics, 942.
 ether, 142.
 forced enemata, 760.
 chloroform, 150.
 kamala, 951.
 kousso, 944.
 pepo, 950.
- Tape-worm :**
 picric acid, 851.
 male fern, 949.
 oil of wormseed, 944.
 pomegranate, 950.
 turpentine, 950.
 thymol, 951.
- Tetanus :**
 amyli nitrite, 330.
 cannabis Indica, 210.
 Calabar bean, 303.
 chloral, 198.
 lobelia, 335.
 potassium bromide, 316.
 tobacco, 344.
 urethan, 215.
 antipyrin, 702.
- Tic-douloureux :**
 croton chloral, 205.
 gelsmium, 339.
- Tinea capitis :**
 lime-water, 940.
- Tonsillitis :**
 capsicum, 722.
 guaiac, 617.
- Toothache :**
 chloral camphor, 205.
 cubeba, 894.
 oil of cloves, 719.
 pellitory, 894.
- Trichiniasis :**
 picric acid, 651.
- Triemur nascentium :**
 Calabar bean, 304.
 chloral, 199.
- Tubercular laryngitis :**
 iodol, 595.
 potassium cantharidin-ate, (note) 902.
- Tubercularis :**
 arsenic, 562.
 arsenic iodide, 662.

A TREATISE ON THERAPEUTICS:

COMPRISING

MATERIA MEDICA AND TOXICOLOGY.

INTRODUCTION.

IN the treatment of acute disease it is essential that the doctor in charge superintend very carefully the nursing and hygiene of the sick-room, since the result of treatment may depend even more upon these so-called minor considerations than it does upon the administration of drugs. In the treatment of chronic disease the best results are to be achieved by the regulation of the habits and mode of life of the patient, and by the employment of certain remedial measures other than drugs. Of late years the importance of modes of relief other than medication has so grown in my estimation that I have concluded in this edition to consider them at some length, and have consequently divided the work into two parts. In the first of these are discussed those methods of therapeutics which are independent of medicinal substances, while the second part is devoted to the consideration of drugs.

PART I.

REMEDIES, REMEDIAL MEASURES, AND REMEDIAL METHODS WHICH ARE NOT DRUGS.

PRELIMINARY CONSIDERATIONS.

THE scope of the first part of this book might perhaps with advantage have been made wider than has been done, and certain procedures discussed which have been omitted. This, however, would have increased beyond proper limit the size of the treatise, and I believe the reader will find most therapeutic subjects which are purely medical and have any importance sufficiently considered. As the various subjects treated have no intrinsic relations with one another, I have found it impossible to make anything like a scientific classification; but for the sake of convenience the matter has been divided into four chapters, as follows:

Chapter I.—General Considerations and Various Miscellaneous Remedial Measures, including Massage, Metallo-Therapy, and Feeding of the Sick.

Chapter II.—Treatment of General Bodily Conditions, including Exhaustion, Obesity, and the Gouty Diathesis.

Chapter III.—Heat and Cold.

Chapter IV.—Electricity.

CHAPTER I.

GENERAL CONSIDERATIONS—MASSAGE—METALLO-THERAPY— FEEDING OF THE SICK.

GENERAL CONSIDERATIONS.

IN the treatment of chronic disease it is of the utmost importance that the physician inquire minutely into the personal habits of the patient and insist upon their regulation in accordance with the needs of the case. The importance of the alcoholic habit as a cause of local and constitutional disease is recognized by many who fail to perceive as clearly the effects of the excessive use of other stimulants. Insomnia, general nervousness, and various cardiac derangements are frequently the result of the tobacco habit, and will not yield to any treatment until the abuse is corrected. Headache, general unrest, nervousness, and many other symptoms may be the outcome of excessive tea- or coffee-drinking, and especially is this the case when these nerve-stimulants are employed to enable the victim to continue excessive labor. Among the lower classes, and pre-eminently among sewing-women the nervines just mentioned frequently replace substantial food, and the resulting headaches and nerve-failure are to be relieved only by a total alteration of the food-habits. The physician should also carefully study the clothing of his *clientèle*: especially is this necessary in regard to young children. Some mothers so overload the child as to keep the skin in a condition of habitual relaxation, to impede the natural, free movements, and to cause general overheating. More frequently, however, young children are clothed too little than too much. Bare legs and bare arms in cold climates are a fertile source of illness. There cannot be two opinions in regard to the superiority of wool over cotton as a material for underclothing. The well-known effect of wet clothing in causing colds is due to the rapidity with which it conducts heat away from the body. Wet cotton is almost as good a conductor of heat as water itself, whereas woollen garments when wet still resist the passage of heat. During exercise cotton underwear becomes damp with perspiration, and in the subsequent cooling of the body fails almost entirely as a protective, whereas a woollen shirt under similar circumstances maintains the temperature of the vital organs. Modern merino underclothing is essentially cotton, and is entirely unfit for wear by delicate persons in cold or changeable climates. Persons who suffer from frequent catarrhs or

are of a rheumatic or gouty diathesis, or whose nutrition is habitually feeble, should always wear next to the skin either wool or silk. When the question of expense is not vital, heavy silk undergarments are as serviceable as those made of wool, and, indeed, in rheumatic cases, in my experience, are superior to woollen underwear. In very many persons, and especially in those who suffer from frequent diarrhoeas and indigestions, or derangements of the abdominal viscera, the abdominal bandage should be habitually worn, in addition to the ordinary underclothing. It should be sufficiently wide to cover the whole abdomen, should be either of silk or of wool, and should be so made as to be readily put on and to fit closely to the body. A simple piece of flannel of sufficient size, secured in its place by means of ordinary safety-pins, makes, perhaps, as serviceable an abdominal bandage as can be obtained. Both abdominal bandage and underclothing should be worn at night, although, for purposes of cleanliness, it is preferable to change them upon going to bed.

The physician should always inquire into the bathing-habits of the patient. Cleanliness and the maintenance of the proper condition of the skin require the use of the bath at least twice a week. In some very delicate persons the general bath produces marked depression, but this can almost always be avoided by the use of very hot water. If the hot or warm bath be employed habitually, it should be preferably taken at night, and, unless under very exceptional circumstances, the hot bath should always be immediately followed by cold sponging or the cold shower-bath, or by a plunge into cold water.

MASSAGE.

The term *massage* is used as the generic name for external manipulations which are employed for the purpose of affecting the nervous and muscular systems and the general circulation. Such procedures have been used from time immemorial upon both man and the lower animals. The rubbing and grooming which the race-horse receives after the contest is a form of *massage* which is paralleled by the rubbings and manipulations employed by the early Greeks and Romans after the struggles in the arena. The power of *massage* was recognized by Hippocrates and Celsus; and it is affirmed that allusions to it can be found in the writings of the Chinese as far back as three thousand years before the Christian era. In Japan for many years the practice of *massage* has been by law entirely in the hands of the blind, who acquire, by virtue of the increase of the power of touch which follows the loss of sight, marvellous dexterity, and the natives of the Sandwich Islands formerly practised a form of *massage*, under the name of *lom-lomi*, to whose assiduous use has been attributed the physical superiority of the royal and noble classes over the laboring people. *Massage* is not rubbing of the skin, although it has in all probability grown out of the practice of such rubbing.

The employment of massage for the relief of disease has two distinct directions. In the one case it is used to affect the general condition of the body, and is known as General Massage. In the other case it is employed for the relief of local affections, and is known as Local Massage. Without entering into a detailed discussion of the physiological action of massage, it is sufficient to state that it seems to me established that in general conditions of lack of muscular tone, nervous exhaustion, and failure of the peripheral circulation it is of distinct value, while in some local diseases affecting chiefly muscular tissue its influence is most pronounced. The practice of massage requires a certain amount of native aptness associated with considerable training. It is not, however, necessary for the operator to be, as some writers affirm, either a lady or a gentleman or a highly-educated person. It is essential that the masseur have sufficient knowledge of anatomy to understand the general drift of the circulation and the positions and shapes of the muscles and of the muscle-masses, that he be cleanly and agreeable in person, and that he be possessed of a soft but firm hand and grasp, and of some natural manual dexterity. Even the most detailed descriptions of the methods of massage are scarcely of avail for the purpose of practically learning the art. It is almost essential that it be acquired in the first place by personal instruction, and finally perfected by practice. Any one who essays to learn it solely from books must blunder through a long series of attempts, and finally work out a method more or less peculiar to himself. I do not, therefore, propose to occupy space with a minute description of the methods of massage, but only to sketch the general features in as much detail as may be necessary for the instruction of the physician who is to direct the treatment and judge of the skill of the masseur or masseuse.

Massage is usually practised upon the bare skin, and I think this is preferable, although I have known very skilful and successful manipulators who preferred that the patient should have thin, tight-fitting underclothes. When a male masseur is used for a female patient, motives of delicacy require covering. Except when very firm masses of local exudation are to be overcome by local massage, or when the female patient is very sluggish and fat and requires exceedingly powerful massage to produce reaction, the female operator should always be chosen for the female patient. The question as to whether the skin should be anointed before massage is one concerning which practice differs. The object of massage is to affect not the skin, but the underlying tissue, and when there is special sensitiveness or irritability of the skin there can be little doubt as to the imperative necessity of some ointment. Vaseline may be employed. A very excellent material is pure and fresh cocoanut oil. Only so much of the grease should be used as is necessary to render the skin soft and pliable and to enable the fingers to glide easily over it.

The movements of general massage vary in detail in the practice of different manipulators. They may, however, all be arranged in three groups: first, effleurage, or stroking; second, pétrissage, or kneading; third, tapctement, or percussion. In properly-performed general massage all these movements are practised at a single séance in the order in which they have been named. It is indifferent whether the operator commence at the hands or at the feet, but the stroking movement should always precede the others, and be directed from the distal portions of the body towards the centre. In making the strokes both hands are employed. The limb is grasped with one hand just above the other in such a way that pressure is exerted to some extent by the whole palm, but especially by the ball of the thumb and the inner surface of the last two phalanges of the fingers. The strokes are delivered in the form of an ascending spiral, the two hands being moved simultaneously in opposite directions, the lower following closely upon the upper; or, in accordance with the practice of other manipulators, the hands are moved alternately, the second hand taking up the motion of the first hand where it has ceased, and while the movement is being executed by the second hand the first hand returning to its original position. The strokes must be made firmly and with great regularity.

In kneading, the endeavor of the operator is to pick up the individual muscle or muscle-groups between the fingers of the two hands, or in some cases between the thumb and finger of one hand, and then to roll or squeeze the muscle with a double movement. The primary, or pinching, motion is made at right angles to the long axis of the muscle, while the secondary movement—i. e., the series of pinchings—is carried from the insertion of the muscle towards its origin. If the muscle be long and small, so that one hand will suffice for the operation, the second hand should follow rapidly upon the first in duplicating the stroke.

Percussion is made either with the points of the fingers brought into a line with one another, or with the side of the hand and fingers,—in either case the fingers being so held as to have looseness and elasticity. The blows should be very rapidly delivered, each individual blow being at right angles to the fibres of the muscles, and the whole series of blows ascending from the insertion towards the origin of the muscle.

During prolonged muscular inaction, whether from indolence, disease, feebleness, or other cause, the muscular structure itself suffers some degradation, and the peripheral circulation becomes very feeble. Much of the albuminous liquid which escapes from the blood-vessels and diffuses itself through the tissues, after serving the purposes of nutrition, is taken up by the lymphatic system and returned to the great blood-vessels. If there be any *vis a tergo* driving this liquid from the periphery to the centre, it is so feeble that the return of the

juices depends chiefly upon the squeezing of the various juice-channels during muscular contractions. During habitual inactivity the movement of fluids in the juice-channels outside of the blood-vessels is excessively sluggish, and it is one great object of the stroking movements in massage to force these juices onward; it is for this reason that these movements are directed from the periphery towards the centre. It is not probable that the whole effect of the stroking is mechanical. The influence of peripheral nervous irritations upon internal organs and upon the general circulation is recognized by almost every one, and every invalid knows the power of soothing strokes and touches in relieving nervousness and even pain; while the phenomena of so-called animal magnetism indicate very strongly that in susceptible individuals apparently trivial peripheral irritations may produce profound alterations in the functional activity of the cerebrum. General stroking movements, if properly administered, are to most persons very quieting, and not rarely, when opportunity is afforded, general massage is followed by quiet sleep.

The kneading and percussion movements of massage act chiefly upon the local circulation. By an indirect or reflex action both of these processes are believed to have a very distinct effect upon the capillary circulation in the parts which receive them, an effect which is precisely parallel to the redness of the skin which follows a smart, stinging blow with the palm of the hand. Kneading performs, however, still another function. As the result of distinct pathological exudations, such as occur in rheumatic muscular affections and even as the result of simple inaction or of a general non-specific but bad condition of the system, the fibres of muscles within their sheaths or the neighboring individual muscles through their sheaths become agglutinated, and even the skin itself may get to be abnormally tense and attached to the subdermic tissue,—a condition which, when it occurs in the lower animals, is known as "hide-bound." Kneading especially has power to remove this condition by mechanically loosening the agglutinated fibres and by so stimulating the local circulation as to cause absorption of exudations. It is especially in the carrying out of kneading and percussion that a knowledge of general anatomy of the muscles is required.

General massage is employed advantageously in various neurasthenic conditions, and forms an important part of the system of treatment known as the Rest-Cure (see page 41). When there is marked feebleness or nervousness, massage should at first be practised very gently, but, except in rare cases, it will soon be found grateful to the patient. During the processes of the rest-cure, both massage and the faradic current will frequently reveal the existence of unsuspected spots of tenderness in various parts of the body. It is probable that such tenderness marks local congestions, and in practice I have found the best results follow from the gradual but per-

sistent application, day after day, of increasingly powerful massage and very rapidly interrupted faradic currents to the centres of tenderness, which almost invariably disappear sooner or later. Closely allied to these sore spots is the tenderness of the so-called spinal irritation, or spinal anæmia. When this spinal tenderness is pronounced, great care is necessary in the gradual application of massage and the faradic current to the affected region. If the operator be sufficiently careful at first to work only upon the borders of the tenderness, and gradually to approach the centre, excellent results can usually be obtained. Under these circumstances massage is useful not only as part of the general plan of treating the constitutional condition, but also by its local power in dispersing congestions and allaying nervous irritations. In some cases the spots of local tenderness are distinctly hard, or the hardness and the sensations of knots or solid places in the flesh imparted to the hand of the masseur may be even much more pronounced than the tenderness. In such instances the local congestion has gone so far as to produce exudation, and there is agglutination of tissues. Massage may be of great service in dispersing the exudations, and should be assiduously practised over the affected parts. There is reason to believe that even glandular enlargements and dilatations of lymphatic channels can be affected by external manipulations.

The first séance in general massage should not last longer than twenty minutes to half an hour, but in a little time a full hour will be required. When there is lack of digestive power, constipation, or any similar symptom,—the outcome of sluggishness of the abdominal circulation and nerve-supply,—local massage of the abdominal and pelvic region should be freely employed.

Abdominal massage for the purpose of affecting circulation in the intestines should be performed as follows. For one or two moments the abdominal muscles themselves should be kneaded, the individual movements being transversely directed across the muscle-fibres; next, in order to influence the small intestines, a series of circular sweeping strokes should be made around the umbilicus, one hand following the other rapidly so as to complete the circles, firm pressure being instituted with the outer portions of the palms; then kneading movement should be performed, beginning at the region of the ileo-cæcal valve, each movement being transverse to the course of the large intestine, the series of the movements following the large intestine upwards to the hypochondriac region, then transversely, and finally downwards along the whole course of the colon. In some cases, especially when there is enlargement of the liver with torpor, good is to be achieved by kneading movements directly over and upon the diseased organ. When along with the enlargement of an abdominal viscus there is a condition of softness, great care should be exercised not to injure the organ by too firm pressure. This applies especially to the pulpy condition of the spleen sometimes seen in malarial disease.

The treatment of *sprains* by local massage belongs to the province of surgery rather than to that of medicine, and I have had little experience with it. I have in a few cases found it very useful after the first stages of irritation and inflammation had passed. I do not think that massage ought to be practised within forty-eight hours after a severe sprain. In *muscular rheumatism* or chronic inflammation of the fibrous tissues about the joints local massage is of very great value, especially when combined with judicious passive movements. The good achieved is probably the result of the breaking up of adhesions between and within muscles, of the mechanical dispersion of exudations, and of increase of the local circulation, with its consequent absorption of exudation. The important movements are those of kneading and percussion. Whilst the individual movements of kneading or of striking are chiefly at right angles to the course of the muscle, the whole series of pinches or blows should always progress along the muscle, and usually from the point of insertion towards the origin. The attempt should be to knead not only individual muscles, but also muscle-groups, and the movements should be directed especially to the breaking up of adhesions.

In various forms of paralysis local massage is of great value as a means of maintaining the nutrition of the affected muscles. When the lesion which produces the loss of power affects the cerebrum, the muscles do not suffer in their nutrition except secondarily from inactivity, and massage is usually not required in the early weeks of the affection. After a stroke of *hemiplegia* it is rarely proper to begin massage for two or three weeks; but whenever the temperature of the arm decidedly and permanently falls, or serous exudation into the cellular tissue marks a loss of vascular tone, or when evidences of returning control over the muscles are manifest, local massage is often of service. At first the séance should not last more than five minutes, but after a time it may continue for ten or even fifteen minutes. In those forms of palsy, such as *infantile paralysis*, in which the trophic centres in the spinal cord are especially implicated, massage is of great importance. In acute cases it should be commenced as soon as the subsidence of fever and other symptoms of constitutional irritation marks the passage of the first stage of activity in the spinal lesion. When the infantile paralysis develops gradually, massage may be employed as soon as the paralysis is recognized. It does not directly influence, to any extent, the fundamental spinal lesion, but, by maintaining a healthy condition of the peripheral apparatus, is of the greatest service in those cases in which there is a tendency to more or less complete repair of the structure of the spinal cord. In various *local paralyses*, as from pressure, from rheumatic affections of the nerves, or from other temporary or removable conditions of nervous or muscular tissue, massage may do much good. When the loss of power in a muscle is due to direct violence, as occurs with especial frequency

in the deltoid muscle from falls on the shoulder, massage should be assiduously employed as soon as the primary inflammation produced by the injury has subsided. In such cases the treatment is of especial advantage in dispersing exudations and restoring the muscles and the muscle fibre bundles to their normal relations and their normal looseness.

FEEDING OF THE SICK.

The present article is not a treatise upon diet or dietetics; the books upon this subject are sufficiently numerous, but their scope is often too wide for the needs of the medical practitioner. In elaborate discussions upon the contained percentage of nitrogen and general food-qualities of various articles of diet, upon their cost and commercial history, upon the amount of food necessary to sustain life, and upon the most economical forms of military, prison, and hospital rations, etc., the consideration of the feeding of the sick in private practice is often so overwhelmed as to be lost entirely. I propose to give here a brief practical summary of the methods of feeding in sickness when pecuniary considerations are of secondary importance.

The proper feeding in acute diseases accompanied with high fever varies to some extent according to the individual affection, but is subject to general principles which are sufficient practical guides for most cases. All such acute diseases are for present purposes readily divided into those in which the acute febrile stage is very short and those in which it is prolonged. When the acute febrile stage is very severe and temporary, it is usually associated with a complete anorexia, which the practitioner may obey with safety. In the first day or two of the onset of an acute pneumonia, violent scarlet fever, or similar affections, there is no cause for alarm even if the patient take no food. The digestive power at this time may be in complete abeyance. After, however, the first day or two of such an attack, and whenever the febrile reaction is prolonged, a loss of appetite amounting even to a disgust with food is no excuse for abstinence. All such states, with their accompanying diseases, tend to fatal result through exhaustion, and much can be done by proper feeding to prevent complete failure of vital power. The older writers upon dietetics taught that a fever patient was not to be fed, and some modern authors reiterate the old dictum. Fever is not, however, any contra-indication to food. It is, indeed, usually associated with loss of digestive power, and if under such circumstances the stomach be overloaded with coarse food the symptoms will be aggravated by the resulting acute indigestion. The amount of nourishment received by a body is measured not by the amount of food put into the stomach, but by the amount which is assimilated; and in febrile complaints the effort of the physician must be directed not to the filling of the stomach, but to the obtaining of as large an assimilation of food as is possible with-

out disturbing the alimentary canal. Any symptoms of gastric or intestinal disturbance should be the signal for the immediate lessening of the food. Such gross manifestations as vomiting, sour or nauseous eructations, and gastric distress are perceived at once by the most careless; but in typhoid fever I have seen skilful practitioners overlook the real cause of an excessive tympany or an increased diarrhoea, and continue the overfeeding while attempting to relieve these symptoms by medicines. Such practice is exceedingly reprehensible. In febrile adynamic diseases the feeding should be at short intervals, with small amounts of liquid food of a nutritious, easily-digested character, and my own experience leads me more and more to the habitual use of foods which have been partially digested artificially.

The question of night-feeding in severe cases is an important one. My belief is that death occurs much more frequently in adynamic diseases between one and five o'clock in the morning than at any other time,—a circumstance largely attributable to the habitual withholding of food and stimulants during the night. Sleep is essential to the recuperation of vital force, but an exhausted patient usually goes to sleep readily after the partial awakening which is sufficient for the administration of a milk punch, or else sleeps in so broken a manner that the careful nurse can give the food at short intervals without awakening him. In no typhoid case of severe type should an interval of more than three hours be allowed to elapse at night without food and stimulants, and the amount given at a single time should be so increased that almost as much will be taken during the night as during the day.

In typhoid cases alcohol in some form should be given with the food, in not too large proportion. Alcoholic liquors in moderate amount stimulate the stomach and aid digestion and absorption, but in large amount interfere with these processes. It may be set down as a general rule with few exceptions that all foods given in protracted febrile states should be in liquid form.

Liquid foods may be divided into Liquid Meat Foods, Milk Foods, and Artificially Digested Foods.

LIQUID MEAT FOODS.—It must be remembered that all articles of the present class are stimulants rather than nutrients. Most of them do not contain more than one per cent. of albuminous substances. Under this heading I include all liquid preparations of meat made without artificial digestion.

At one time these liquid preparations of meat were supposed to represent the whole nutritive value of the meat, but recently all nutritive power has been denied to them. They contain kreatin, kreatinin, sarkosin, sarkin, xanthin, kreadin, inosite, fat, and inorganic salts, with a very small amount of albuminous principles. It is not probable that any of these substances, except the albumen and the fat, are capable of being assimilated and used as food. The experiments of Kemmerich also indicate very strongly that they are not nutrients, for

he found that animals fed exclusively upon these preparations died even more quickly than those left to starve. There can be no doubt that the death under these circumstances was largely due to the depressing effect of the inorganic salts contained in the extracts. Clinical experience, in a measure, conforms with this scientific reasoning. At a time when beef essence and beef tea were very largely relied upon as nutrients in Philadelphia, it was found that they acted better when milk was also given. In my earlier trips into the wilderness, involving much physical labor, I took with me the best artificial meat extracts to serve as condensed food, but, after a few trials, found that they were unable to sustain prolonged effort,—as the guides put it, “they do not stick to a man’s ribs,”—and, although at that time my theory was that they were concentrated nourishment, practical experience soon led to their abandonment. Although of little use as food, these substances are valuable stimulants, and may by reviving temporarily an exhausted patient prepare the way for the digestion of food. In a series of experiments made upon the frog’s heart by Dr. Thomas J. Mays (*Therap. Gaz.*, vol. ii. p. 152), it was found that the artificial beef extracts and concentrated beef preparations had a very decided influence in maintaining the activity of the systoles. Notwithstanding Dr. Mays’s arguments to the contrary, however, I believe that the effect of beef extracts upon the frog’s heart is entirely similar to that of the phosphate of calcium (see CALCIUM PHOSPHATE). In typhoid and other similar low fevers, it is an excellent plan to give beef essence or beef tea alternate hours with milk punch. During convalescence a hot bowl of beef tea or beef essence after exertion such as carriage-riding, going out, etc., may act very well as a stimulant. By the addition of various substances these liquid preparations of meat can be made nutritive: thus, an egg rapidly stirred into a bowl of beef essence forms a very useful stimulating food. There are in the market various extracts of beef, claiming to represent, in a solid form, beef essence. The better forms of these articles undoubtedly do represent in great part beef essence, but they are distinctly inferior to the freshly-made preparation in taste, and in containing no albumen: so that it is always better to employ the fresh beef essence if it can be procured.

Liquid meat foods are divisible into those that are raw and those that are cooked. Of the raw foods of the class, the best is *meat juice*. This is made, according to the directions of Pettenkofer and Voit, by selecting lean meat from the round of beef, cutting it into small pieces, and expressing the juice in a press of sufficient power,—such as now can be purchased at any of the larger drug-stores. This juice contains, in addition to the salts and extractives, the albumen that remains fluid after the rigor mortis,—chiefly serum-albumen and coloring-matters. The proportion of albumen is about six per cent.: by heating the albumen is precipitated, but it is not affected by salt or by more warming. *Liebig’s beef tea* is made by adding seven ounces of water and three or

four drops of hydrochloric acid to one and a half pounds of lean beef, allowing to stand one hour, passing through a hair sieve, and washing out the meat with three ounces of water. This infusion contains, on the average, not more than one per cent. of albumen. The hydrochloric acid added to the water is not sufficient to dissolve the myosin of the muscle: so that this preparation can be looked upon as nothing more than a dilution of meat juice, and is very inferior. To have any effect it must be given in enormous quantities.

Meat juice is a valuable preparation when a powerful stimulation is desired and the digestive forces are exceedingly weak, as in the feebleness or collapse that follows cholera infantum and other infantile diarrhoeas. Its taste is that of raw meat, and is so disagreeable to many persons as to prevent its use.

The cooked concentrated liquid forms of meat extracts are beef tea and beef essence. Neither of these can be considered to have distinct nutritive value. It is very rare for them to contain more than one per cent. of albuminous substances; but they are powerful stimulants, and for such purposes are as useful as the expressed meat juice.

In making *beef tea* the round of a good piece of beef should always be selected, and cut into small cubes not larger than half an inch in diameter. It should then be put to soak for two hours on the back of the range, in an earthen-ware pipkin, with one pint of cold water, and allowed to simmer for about fifteen minutes and finally to boil for three minutes. After adding half a teaspoonful of salt and a little pepper the tea is ready for use.

In making *beef essence* the meat should be prepared as for beef tea. It should be put into an earthen-ware bottle and loosely corked. This should be set in a pot of cold water and brought very gradually to the boiling-point. It then should be allowed to boil for from twenty minutes to half an hour.

Soups are liquid preparations which resemble beef tea and beef essence in containing the extractives of meat, but which differ from these preparations in having in them various nutritive substances. Soup is therefore both a stimulant and a nutrient, the amount of nutrient material varying greatly according to the preparation of the soup. The lighter forms of soups are commonly spoken of as broths. They may be used when the stomach rejects less readily digested forms of food.

To make *chicken broth*, take three pounds of chicken well cleaned, cover with cold water, boil from three to five hours (until the meat falls to pieces), strain, cool, and skim off the fat. To a pint of this add salt and pepper and two tablespoonfuls of soft rice which has been previously thoroughly boiled in salt water; bring the broth to a boil. In preparing the rice, half a cupful should be boiled for thirty minutes with a teaspoonful of salt in a pint of water. To make *mutton broth*, take one pound of lean, juicy mutton, chopped fine, and proceed as with chicken broth.

In the preparation of soups the first thing is the making of the so-called stock, or basis for the soup. There are two distinct stocks: one which may be known as the brown stock, the other as clear stock or *consommé*. For the preparation of *brown stock* take four pounds of shin of beef, four quarts of cold water, ten whole cloves, four peppercorns, a bouquet of herbs (sweet marjoram, summer savory, thyme, and sage), one tablespoonful of salt, three small onions, one turnip, one carrot, two stalks of celery, two sprigs of parsley. Cut the meat from the bones, after which place the bones and one-half of the meat in a soup-kettle and allow to stand for half an hour in the cold water. Heat gradually, and allow to simmer for six or seven hours. Brown the remainder of the meat in two tablespoonfuls of beef-drippings, and add with the other meat and with the vegetables chopped fine, when the kettle is put on the fire to simmer. After it has simmered the required time, the stock is strained and set aside to cool, the fat being removed from the top. The stock is then ready for use.

In making the soups the stocks must never be allowed to boil, or at most must be brought only for a moment to the boiling-point. For *St. Julien soup* put one pint of the brown stock on the fire to heat, after which a pint of finely-chopped vegetables (turnip, carrot, etc.), with half a teaspoonful of salt, should be put on with a little water to parboil. This being done, add the vegetables to the stock, and season with half a saltspoonful of pepper. *Vermicelli soup* is made by adding half a cup of vermicelli to a pint of the brown stock. Cook the vermicelli for ten minutes in salted boiling water, season with a half-teaspoonful of salt and a half-saltspoonful of pepper, and add to the warm stock.

Consommé or *clear stock* is to be made in exactly the same way as the brown stock, except that three pounds of the knuckle of veal are to be added to the meat, and all the meat is to be put in at once without browning. After the stock has been formed, in order to clear it add the white and the shell of one egg, and the juice and rind of one lemon, beating them all up together; then put on the fire, bring to the boiling-point, strain through a sieve, and again through a napkin, without pressure or squeezing, and serve.

A very elegant stimulating and nutritious soup can be made out of *consommé* by boiling ordinary pearl sago in salt water for from two to three hours, until the grains become swollen almost to bursting, and then stirring the sago into the *consommé* while still boiling.

MILK FOODS.—Of all liquid foods milk is the best and the most generally applicable to the treatment of disease. Cow's milk contains, in round numbers, 87.5 parts of water, 3 parts of caseine, 0.75 part of albumen, 3.6 parts of fat, 5 parts of sugar, and 0.07 part of inorganic salts. One pint of milk contains, in round numbers, 0.6 ounce of solid albuminous substance, 0.6 ounce of fat, and 0.8 ounce of sugar. When two quarts of milk are taken in the course of twenty-four hours, about

two and a half ounces of fat are ingested,—an amount too great for an inefficient alimentary canal to digest, so that it is often necessary to skim the milk. As milk contains practically no indigestible residue, it leaves behind it in the alimentary canal no fecal matter, and its use therefore frequently produces constipation. In cases of diarrhoea this tendency to a binding action can be increased by boiling the milk, a process which coagulates the albumen of the milk and slightly lessens, if the scum be removed, its nutritive value. When milk is used very freely and the digestion is feeble, there is always danger of the formation in the stomach of a coagulum so dense that the gastric juice will not be able freely to penetrate it. This difficulty can usually be overcome by a little care. The addition of half an ounce to an ounce of lime-water to every five or six ounces of milk has a distinct tendency to prevent too rapid and firm coagulation. Sipping milk instead of drinking it—in other words, putting the milk in the stomach in small quantities at a time—has a still greater power in repressing the formation of hard coagulum. When the digestive powers are feeble, milk should be taken slowly in small quantities at a time. In some cases it is very important that it be drunk hot, but without previous boiling.

There are various useful nutrient and stimulant foods prepared with alcohol in milk, as follows:

WINE WHEY.—Bring half a pint of milk to the boiling-point; add half a pint of sherry wine, and allow to stand in a warm place for five minutes; strain, and sweeten to taste. The whey which is left consists almost exclusively of wine and water, with milk sugar and milk salts. It contains very little nutriment, but is sometimes tolerated by the stomach which refuses other food.

MILK PUNCH.—Take half a pint of milk; pour into it from a dessertspoonful to a tablespoonful of brandy, rum, or whiskey, according to the needs of the patient; sweeten and spice with nutmeg to taste. This preparation represents all the nutritive value of milk and the stimulating effects of the liquor. If the stomach be at all delicate, a tablespoonful of lime-water should always be added to it before putting in the brandy.

Eggnog.—Eggnog is a heavy, rich, highly nutritive liquid, which must be employed in limited quantities, and very carefully when there is any delicacy of stomach. The yolk of one egg may be added to half a pint of milk, afterwards half an ounce to an ounce of brandy, and the white then beaten in.

Sometimes when the stomach rejects almost all forms of food, the addition of carbonic acid water to the milk meets with success. Equal quantities should be employed, and the caseine of milk should be coagulated in fine flakes. A light, powerfully stimulant beverage, somewhat similar to the one just mentioned, but to some palates more elegant, is made by the addition of champagne to milk.

There are certain forms of fermented milk which are valuable as

being easily digested by the stomach and very acceptable to the palate. They also render possible some variety of food to persons largely restricted to milk diet.

KOUMISS, or KUMYS, is a fermented liquid prepared by the Tartars from mares' milk. It may for ordinary purposes be sufficiently imitated by the following recipe. Take an ordinary beer-bottle with a patent shifting cork, put in it one tablespoonful of white sugar, one pint of milk, one-sixth of a cake of Fleischman's yeast or one drachm of strong liquid yeast, shake well, allow to stand from eight to ten hours in a temperature of from eighty-five to ninety-five degrees, shake well, and put upon the ice to cool. This ought to be used within twenty-four hours after being made. The longer the fermentation is allowed to continue, the more sour is the koumiss; and its condition should be regulated to suit the individual palate and stomach of the patient. If it be desired, it may be flavored by the addition of a small piece of vanilla bean to the milk before fermentation. This preparation is suited to the treatment of convalescence and chronic diseases rather than of acute febrile illness.

Milk may be used as the basis of a number of farinaceous or starchy liquids. It must be remembered that these starchy compounds are more or less difficult of digestion, and during the progress of an acute, severe febrile illness they must be employed with the greatest caution. In convalescence and in chronic invalidism, however, they are often very serviceable. In making these preparations it is essential that they be closely watched and stirred, to prevent burning, unless they be cooked over hot water.

OATMEAL PORRIDGE may be made by stirring two ounces (half a cupful) of crushed oatmeal into a pint of milk, previously warmed, and afterwards cooking twenty to thirty minutes, adding salt to the taste.

BAKED FLOUR PORRIDGE.—A very excellent porridge, of easy digestion, and especially valuable when there is a tendency to looseness of the bowels, can be made by the following recipe. Take one pint of flour and pack it tightly in a small muslin bag, throw it into boiling water and boil for five or six hours, cut off the outer sodden portion, grate the hard core fine, and stir into boiling milk to the desired thickness.

ARROW-ROOT PORRIDGE.—This may be prepared in the following manner. Stir two teaspoonfuls of arrow-root in half a teacupful of cold milk until a *perfectly smooth* mixture is made; have on the fire a pint of milk, and, while this is boiling, add the arrow-root little by little, stirring constantly until cooked,—i.e., from one to two minutes after the last is poured in; add sugar, nutmeg, and wine, according to taste or the exigencies of the case. When milk is not to be had, or a very low diet is required, water may be substituted.

The secret of properly-prepared arrow-root is in having the first mixture with milk absolutely smooth and free from lumps.

CHOCOLATE PORRIDGE.—A gruel which will be found very palatable to many persons, and may be substituted for simple arrow-root, can be made by the following recipe. Mix together one-quarter pound of best chocolate grated, one-half pound of rice flour, two ounces of arrow-root, and one-quarter pound of loaf-sugar grated. Add a tablespoonful of this mixture to a pint of hot milk, and let it boil five minutes. Then remove the preparation from the stove and serve it hot. It should have the consistency of gruel.

TOMATO PORRIDGE.—A very excellent porridge or *purée*, highly nutritious and useful during convalescence, can be made by the following recipe. Take one quart of canned tomatoes, bring to a boil, strain while hot through a hair sieve; bring a quart of milk to a boil, add sufficient flour to make a thick paste, stir in, and continue to boil until the flour is cooked (about twenty minutes). Stir the strained tomatoes gradually, a little at a time, into the boiling milk. Cook five or ten minutes; season to taste.

SAGO PORRIDGE is of the consistency of a jelly rather than of a porridge. In preparing it, wash the sago well in cold water, put a small teacupful of it to soak in half a pint of water over-night, and in the morning put this mixture into one pint of hot water; squeeze into it the juice out of a thinly-pared lemon, and allow to simmer slowly for twenty minutes; then sweeten, add wine according to taste or the exigencies of the case, and pour into moulds to cool.

TAPIOCA PORRIDGE is very elegant, but, like sago porridge, requires considerable time for preparation. It may be made in the following manner. Soak two tablespoonfuls of very clean tapioca in two teacupfuls of cold water over-night; in the morning add a little salt and one pint of milk, or water if milk is not allowed; simmer it until quite soft; stir well while cooling; when done, pour into a bowl, and add sugar, wine, and nutmeg, according to taste or the exigencies of the case.

ARTIFICIALLY DIGESTED FOODS.—In low fevers the powers of the alimentary canal are certainly much impaired, and foods which have undergone more or less complete artificial digestion outside of the body are very useful.

In all cases in which the typhoid symptoms are severe, milk should constitute the chief reliance, and should be partially digested before administration. When the disease is prolonged, and especially when the mental condition is clear, the patient frequently tires of milk. Under these circumstances various liquid foods prepared by the partial digestion of solids are of great importance. Artificially digested foods are also of value during convalescence, and their employment constitutes a very important part of the treatment of gastric and intestinal catarrhs. Most peptones have a distinctly bitter taste, which may be very objectionable in individual cases. This taste can be partially overcome by the addition of flavoring substances or ex-

tracts, and often may be altogether avoided by arresting the process of artificial digestion before completion.

At first thought pepsin would appear to be the most available ferment for the preparation of peptones; but practical experience has led to reliance upon pancreatin. Pancreatin, pancreatic extracts, and pancreatic liquors are now found abundantly in commerce. The superiority of the secretion of the pancreatic gland as a practical ferment is connected with the fact that it contains two distinct classes of digestive principles, namely, pancreatic diastase, which dissolves starch, and trypsin, which acts upon albuminous principles. It is of great importance to be able to determine readily the value of any preparation of pancreatin. The test devised by Dr. Wm. Roberts (*Digestive Ferments*, London, 1881) appears to be very practical. If pancreatin be added to fresh milk without an alkali, in the course of a few minutes the liquid acquires the property of curdling abundantly upon boiling; and Dr. Roberts estimates the value of a pancreatin by the number of cubic centimetres of milk which are transformed by one cubic centimetre of the sample at a temperature of 40° C. to the curdling-point in five minutes. The liquor pancreaticus used by Dr. Roberts had a power oscillating between fifty and seventy. A test which may be substituted for that of Dr. Roberts, and which is especially applicable to the ordinary pancreatic extracts or so-called pancreatin, is based upon the peptonizing power of the powder. Five grains of it added to twenty grains of the bicarbonate of sodium should so alter the caseine contained in one pint of milk in an hour at a temperature of 115° F. that no coagulation will occur upon the addition of nitric acid.

Peptonized milk is made by diluting a pint of milk with a quarter of a pint of water, heating to about 140° F., adding two teaspoonfuls of liquor pancreaticus (Roberts's) with twenty grains of bicarbonate of sodium, digesting in a warm place for an hour to an hour and a half, and raising momentarily to the boiling-point; at the temperature of the sick-room, 65° F., the digestion will usually require about three hours. Or milk may be peptonized by dissolving five grains of pancreatin with twenty grains of bicarbonate of sodium in an ounce of warm water, adding to a pint of milk, and keeping at a temperature of 110° for one hour. Very many persons object to the bitter taste of the thoroughly digested milk, so that in practice the best results are often obtained by allowing the peptonizing process to be only partially completed, and giving the milk after it has been acted upon by the ferment not longer than twenty to thirty minutes.

Peptonized milk gruel is made by first preparing a thick gruel with arrow-root, oatmeal, sago, or other similar farinaceous articles, adding, while still hot, an equal quantity of milk, and subsequently, when cooled to 100°, for each pint twenty grains of the bicarbonate of sodium and two teaspoonfuls of the liquor pancreaticus or five grains

of pancreatic extract, digesting in a warm place for two hours, boiling the mixture momentarily, and straining.

Peptonized beef tea is prepared by simmering half a pound of minced beef for two hours in a pint of water containing twenty grains of bicarbonate of sodium, allowing to cool to about 100° F., digesting at this temperature with a tablespoonful of liquor pancreaticus or ten grains of pancreatic extract for three hours, decanting, and momentarily boiling. This beef tea is said to be about equivalent to milk in nutritive value, containing 4.5 per cent. of organic solids, three-fourths of which is peptone.

Peptonized oysters, a very palatable and extremely nutritious dish, is made by mincing six large or twelve small oysters, and adding to them, in their own liquor, five grains of pancreatic extract with twenty grains of bicarbonate of sodium. The mixture is then to be brought to 100° F., and maintained, with occasional stirring, at that temperature for thirty minutes, when one pint of milk is to be added and the temperature steadily kept up for ten to twenty minutes. Finally the mass is to be brought to the boiling-point, strained, and served. Gelatin may be added, and the mixture served cold as a jelly. Cooked tomato, onion, celery, or other flavoring suited to the individual taste of the patient may be added at the beginning of the artificial digestion.

PANCREATIZED MILK TOAST.—Ordinary milk toast, in which there is an abundance of milk, when digested for thirty to fifty minutes with pancreatin and bicarbonate of sodium becomes an almost homogeneous pulpy mass, which, when the crusts have been removed, is usually readily retained by the irritable stomach. In extreme cases, however, it may advantageously be strained and the fluid portion alone used, in which the partially peptonized solution of casein of the milk is reinforced by the actually digested gluten and starch of the bread, together with a very little dextrin. Plain, light sponge-cake may be similarly digested, and occasionally forms a desirable change.

RECTAL ALIMENTATION.—In severe gastritis and in gastric ulcer it is sometimes necessary to enforce a temporary or even a somewhat prolonged abstinence from food. In diphtheritic paralysis of the throat, as well as in strictures of the œsophagus, it may be almost impossible to get food into the stomach, and in various cases the food is vomited whenever it is ingested. Under any of these circumstances feeding by the rectum becomes a matter of the utmost importance. There is no reason for believing that the rectal or even the colonic secretions have digestive power. Absorption goes on slowly from the rectum, but, according to Landois, very rapidly from the colon itself. For these reasons injections which are used for the purpose of nourishing the patient should always be composed of bland, thoroughly digested, concentrated food. Dr. W. O. Leube (*Deutsch. Archiv für Klin. Med.*, 1872) uses a food preparation which he has proved by experiments made upon dogs to be capable of yielding to the blood nutritive material, and by which

he has maintained life for four weeks in a patient poisoned by iodine, whose stomach rejected all food. The method is as follows. The pancreas of swine or cattle is carefully cleaned of fat, and 50 to 100 grammes thereof cut into very small pieces. In like manner 150 to 300 grammes of beef are prepared. Both substances are then put into a dish with about 50 to 150 cc. of lukewarm water, and stirred into a thick paste, and drawn in a clyster-pipe with wide opening. In many cases from 25 to 50 grammes of fat may be added to the mixture, also at times some starch. An hour before using this clyster, one of pure water should be administered, to clean out the intestines. In very warm weather there is some trouble in obtaining and keeping sweet the pancreas. This difficulty may be avoided by making a glycerin extract, which is said to be quite equal in digestive power to the fresh pancreas, and will remain good for several weeks. The following is the manner of its preparation: the pancreas of a bullock (which is sufficient for three enemata) is finely chopped, and rubbed with 250 grammes of glycerin; and to each third of this, when about to be used, are added from 120 to 150 grammes of finely-divided meat. It is important that this mass should be injected into the intestine as soon as it is made; for if it is allowed to stand, the meat swells, and the operation is thereby rendered difficult.

It is evident that the central idea of Dr. Leube's method is simply to offer to the intestine for absorption a well-formed peptone. Dr. L. S. Joynes (*Richmond and Louisville Med. Journ.*, 1869) has found that the stomach of the pig placed in water acidulated with hydrochloric acid will rapidly dissolve not only itself, but also small pieces of beef. Such a preparation might be substituted for that of Leube, but, as its reaction would be acid, it would probably not agree so well with the intestine. The solutions of Leube can very well be substituted by preparations made with commercial pancreatic extracts. As milk and eggs contain all the food necessary for the sustenance of life, and are more rapidly and readily digested than is meat, all that is necessary is to digest them thoroughly before injection. Half a pint to a pint of milk with two or three eggs may be employed at each injection. When stimulants are required, half an ounce to an ounce of brandy may be added to each injection: larger quantities of alcohol than these would be apt to irritate the mucous membrane. The alcohol should always be added after digestion has taken place, and just before administration. A practical difficulty in sustaining life by rectal injections is the frequent refusal of the intestine to retain them. In order to obtain the best possible results, certain precautions are necessary. The colon and rectum should always be free from feces before the administration of the injection. The injection should be given at the temperature of the body, thrown in very slowly, and as high up into the intestine as possible. The effort should be to have the fluid injected into the colon rather than into the rectum. Unless a narcotic is contra-indicated, from twenty to

forty drops of laudanum should be added to each injection. Very rarely is it wise to repeat the injections oftener than twice in the twenty-four hours; and once in six hours is the extreme limit.

METALLO-THERAPY.

In 1849, Dr. Burk discovered that in hysterical anæsthesia it was possible, by the application of metals to the surface of the body, to recall sensibility, and in 1851 he presented an inaugural thesis upon the subject to the Faculty of Paris. It was not, however, until 1876 that he succeeded in attracting the general professional attention of France to the matter. In that year, in answer to his importunities, the Société de Biologie of Paris appointed a commission to examine into the accuracy of his alleged facts. The report of this commission (Paris, 1879) confirmed the statements of Dr. Burk, and also extended our knowledge of the subject. It was found that different individuals have different relations with metallic substances, some cases being affected by zinc, others by iron, others by gold, copper, etc. In exceptional instances the hysterical person has relations with two or even more metals. When a small disk of the appropriate metal is bound over the anæsthetic surface of an hysterical subject, after from ten to twenty minutes a sensation of warmth is developed beneath the disk, and a distinct reddish color appears. At this time the prick of a needle is distinctly felt, even painfully so, not only at the spot over which the plate has been applied, but also in a more or less extended zone around it. In some cases the sensibility returns only in the immediate vicinity of the application; in others the whole arm or, more rarely, the whole side of the body becomes sensitive. With the return of sensitiveness there is a disappearance of the ischæmia, and if motor palsy has existed there is also an increase of the motor power as measured by the dynamometer. In most cases of hysterical anæsthesia there is a distinct coldness of the surface, or, indeed, of the whole arm, and with the disappearance of the palsy of sensation and of motion there is an increase in the temperature. Thus, in a case of right-sided hysterical anæsthesia and amyosthenia the thermometer held in the right hand stood at 36° C., in the left at 34.5° C. (Dr. Dumontpallier, *La Metalloscopie*, Paris, 1880), but after the application of the metal the temperature of the left hand was higher than that of the right. In many instances not only is the sensibility of the skin restored, but at the same time the special senses gradually become nearly normal; although in other cases it is necessary, in order to affect the special senses, that the metallic plates should be in the neighborhood of the orbit or in the temporal region. When achromatopsia is relieved, blue is usually the first color to return, or, more rarely, red. Some minutes after this, yellow is perceived, then green, and at last violet (Dr. Aigre, *La Metalloscopie*, Paris, 1879, p. 23). As seems to have been first discovered by M. Gella, at the time of the disappearance of the anæsthesia under the influence of the metal the

loss of sensibility appears in a corresponding position upon the unparalyzed side, and is accompanied by a fall of the local temperature. In a few cases severe pains have developed during the application of the metals. According to the experience of the French commission, which seems to be identical with that of subsequent observers, the effect of the application is usually in hysteria at first temporary, and lasts from a few minutes to some hours.

Dr. Burk, in his communication to the Société de Biologie, stated that if the metal which had been found temporarily to affect sensation in a person suffering from hysterical anæsthesia were given to such patient in continuous doses, all symptoms of hysteria would, after a time, permanently disappear. The commission confirmed, in a measure, this statement: in sundry cases they found under such administration that menstruation became regular, digestion improved, and the muscular force and sensibility returned. They further, however, made the extraordinary discovery that if a piece of the metal were bound down on the skin of the person who had recovered, a return both of anæsthesia and of motor palsy took place in from twenty to forty minutes.

It having been suggested that the metal upon the skin acts by induction of the feeble galvanic currents, the French commission found that the application of most metals to the surface of the human body gives rise to an electric current sufficiently powerful to be measured, that these currents vary in power with different metals, and that electrical currents of power equal to that of those produced by the appropriate metals applied to the anæsthetic surface brought about a return of sensibility. The observations of M. Luys showed that the application of the appropriate metals was also able to reduce hysterical hyperæsthesia to the normal.

That the phenomena of the so-called metallo-therapy, as I have summarized them, may frequently be obtained, in more or less completeness, is shown by the confirmation of the report of the French commission not only by a number of French observers, but also in England by Dr. A. Hughes Bennett (*Brain*, vol. i. part 3; *Brit. Med. Journ.*, Nov. 25, 1878), in Italy by Buccola and Sepilli (*Lond. Med. Record*, vol. ix.), and in Germany by Dr. F. Gratz (*Ibid.*) and various other observers. It is, however, certain that, at least in this country, they are exceptional. In an elaborate series of observations made in the wards of the Philadelphia Hospital by my colleague Dr. C. K. Mills, the transfer of sensibility was obtained in only a very few cases; while Dr. S. Weir Mitchell affirms, as the result of his great experience, that neither he nor any of his assistants have ever been able to bring about anæsthesia of the sound side, although they have very frequently obtained temporary returns of sensibility by the application of various substances, especially by mustard plasters, and even more pronouncedly by freezing the skin with rhigolene. It was at first believed that the production of sensibility by æsthesiogenetic agents is proof of the

hysterical nature of an anæsthesia; but in the course of his early observations upon the subject, M. Charcot found that even in organic hemianæsthesia the application of the plates of metal was followed in twenty or thirty minutes by a return of the normal sensibility and of the special senses. These observations have been confirmed by several French observers.

It is also asserted that if powerful magnets be used instead of metal plates, in cases of hysterical or organic hemianæsthesia with contractions and motor palsy, there will be relief not only of the paralysis of sensibility, but also of the disturbances of motility. Thus, M. Laboulbène reports a case (*Gazette des Hôpitaux*) of a man, sixty-seven years of age, suffering from organic left hemiplegia and complete hemianæsthesia, in whom the application of a strong magnet was followed by the reappearance, first in the arm and afterwards in the leg, of the normal sensibility, and by marked increase of the motor power in the hand as tested by the dynamometer. It is, however, to be noted that, so far as my examinations of the records go, there has not as yet been reported a case of organic hemianæsthesia in which any transfer of anæsthesia has been noted.

The explanation of the facts of metallo-therapy is a matter of difficulty, and no theory has as yet been offered which is satisfactory. That the phenomena are not the result of the action of a feeble electric current upon the peripheral nerves seems to be shown by their having been produced by metals, such as platinum, which are practically non-oxidizable, and by absolutely inert substances, such as disks of wood, and even, as in the case reported by Bennett (*loc. cit.*), by the application of a handkerchief. The theory adopted by most English writers, that they are the result of expectant attention,—i.e., that they are the result of the patient's believing that the phenomena are about to happen,—is asserted to be disproved by the fact that in many cases the patient did not know what was to happen. The so-called molecular theory, which teaches that there is some mysterious molecular influence produced by the applied plate on the peripheral nerve filaments, amounts to nothing more than words.

CHAPTER II.

THE TREATMENT OF SYSTEMIC STATES.

EXHAUSTION AND NEURASTHENIC CONDITIONS.

DEPRESSION is a condition of temporarily lowered vital activity produced by the presence of some poison in the system. Exhaustion is a condition of absolute lack of power in which the functional activity is repressed not by a depressing substance, but by the inability of the affected part. In practice it is essential to distinguish between these two states. The one requires treatment by stimulants, while the other is often, although temporarily relieved, permanently aggravated by the use of stimulants. Exhaustion, especially of the nervous system, is frequently spoken of as a disease, under the name of *neurasthenia*. It is not a disease, however, but a condition, which may be the result of overstrain or overwork or of some chronic disease. It is essential that in every case of alleged neurasthenia very careful examination should be made to detect the presence of organic kidney-disease, chronic diarrhoea, or other possible cause of the exhaustion. The amount of work necessary to produce neurasthenic exhaustion is dependent upon the original amount of power in the organism. In persons born of neurotic feeble parentage or of parents exhausted by overstrain, the working power may be very slight. Exhaustion may be local or it may be general. This applies to the nervous system as well as to the other apparatus of the body. A local nervous exhaustion tends towards developing into a general condition. Thus, a writer's palsy may be the first symptom of a general break-down. Spermatorrhoea, at first due purely to local exhaustion of the implicated nerve-centres, if unchecked very generally develops into general neurasthenia. The same is true of cerebral exhaustion following excessive mental work. The exhaustion is to be relieved only by recuperation, and recuperation is to be obtained only by rest and the assimilation of food. The nature of the rest depends upon the character of the exhaustion. In cases of pure cerebral exhaustion with the bodily powers untouched and the physical powers not much implicated, freedom from care and from all mental work, conjoined with life in the open air, is the essential of cure. It must be remembered that sight-seeing is as exhausting to the brain as is the hardest study, and that in extreme cases even the seeing of friends may overtax the brain so that isolation may be essential. Such isolation may be obtained, if the bodily powers

remain good, by travel in the wilderness, or on the ocean, or in other positions where intercourse with the world is impossible. In cases of extreme neurasthenia or nervous exhaustion the so-called rest-cure is a method of treatment of great value. It is essential for its successful employment that it be modified to suit the needs of the individual case: if employed as a set mould into which every case is to be forced, it will frequently do harm. Often the best results are achieved by associating certain features of the rest-cure with out-door exercise, such as walking or carriage-riding.

The principles of the rest-cure are absolute rest, forced feeding, and passive exercise. Absolute rest is often prescribed by the physician without being sufficiently definite and insisted upon. When it is desired to apply it most strictly, it should be clearly explained that the patient is not to be allowed to get out of bed even to pass urine or faeces, nor to feed himself or herself, nor perform any act of the toilet whatsoever. The rest also must be for the mind as well as for the body, and it is essential that the patient be isolated. In obstinate, severe cases of neurasthenia complete and absolute isolation is a *sine qua non*, and especially when there is a decidedly hysterical element it is necessary to separate the patient entirely from her friends. Under these circumstances there must be a well-trained nurse who is personally agreeable to the patient. The confinement would be very irksome to any except the most exhausted patient were it not for the daily visit of those engaged in the treatment. To provide further against *ennui*, the nurse should be a good reader, so that under the definite instructions of the physician she can occupy a certain portion of the time in reading to the patient.

In order to maintain the functions of the skin, the patient should be well sponged with hot water in bed every morning after breakfast. A strong solution of salt, or, better, sea-brine, is to be preferred to simple water, and frequently it may be followed by the use of alcohol. In very feeble cases the alcohol may be employed alone. I have seen very good effects from momentarily rubbing each portion of the skin with ice just after bathing. When rubbing with ice is practised, the bath should be hot.

In giving the bath the patient should be stripped, and lie between blankets, so that exposure of the whole body is avoided while each part is thoroughly washed. No exertion on the part of the patient should be allowed. Women should not be permitted to arrange their own hair.

The question of feeding is one of great importance, and requires the utmost care and attention from the physician. The end to be attained is to feed the patient as much as can be digested, but not to overfeed and derange the digestion. Food should be given at intervals of two or three hours, and must be both light and nutritious. It should, at least at first, consist largely of milk, except in those rare cases in which that fluid does really disagree with the stomach and is not merely thought

to do so. The milk should be skimmed or given in the form of koumiss. Beef juice and other concentrated meat essences are valuable as stimulants, and may be used especially as the basis of soups. Various farinaceous articles of food may be added to them: if an egg be broken into the concentrated bouillon or beef essence just as it ceases boiling, a nutritious and to many persons palatable dish is obtained. When constipation exists, oatmeal porridge, Graham bread, and fresh or dried fruits may be allowed if readily digested by the patient. In order to give an idea of a general plan of the dietary, the following schedule of the daily life is given. It must be altered from day to day, so as not to weary the patient by its monotony. Such a schedule should always be put in the hands of the nurse, who should be required to follow it strictly. Success will in a great measure depend upon the practical skill and tact of the physician in his adaptation of the diet to the individual requirements of the case:

8 A.M. Rolls or toast; cocoa or weak coffee, or roasted wheat coffee; beefsteak, tenderloin, or mutton-chop.

9 A.M. Bathing.

11 A.M. Oatmeal porridge, with milk, or else a pint of koumiss.

12 M. Massage.

2 P.M. Dinner: bouillon with or without egg; beefsteak, rice, roast white potatoes; dessert of bread-pudding, blanc-mange, or similar farinaceous articles of diet.

4 P.M. Electricity.

5 P.M. Milk toast.

9 P.M. Half a pint of skimmed milk or koumiss.

In many cases the patient at first can take very little food, and it is frequently best to begin the treatment with an entirely liquid diet, giving milk every two hours, or some nutritious soup, with milk or plain farinaceous food, and only after a time gradually accustoming the patient to solid food. Not rarely a prolonged treatment by the so-called milk diet is of avail. The rest-cure is, indeed, largely based upon a careful regulation of the food.

Passive exercise is to be obtained by the use of electricity and massage, the object being to get the effects of exercise upon the nutrition and circulation without the expenditure of the patient's nerve-force. By the use of electricity muscular contractions are secured that simulate those which are voluntary, and more or less thoroughly replace them.

The faradic current is alone used. It is applied in two ways: first, to the individual muscles; second, to the whole body. The sances should be daily, the operator beginning at the hand or the foot, and systematically faradizing each muscle of the extremities and the trunk.

The slowly-interrupted current is generally preferable, but advantage is sometimes gained by varying the rapidity of the interruptions. The general rule is to select that current which produces most muscular

contraction with the least pain. The poles should be applied successively to the motor points of the muscles, so as to contract each firmly and thoroughly. This process should occupy from thirty to forty minutes. The electrodes are then to be replaced by large sponges well dampened with salt water: one of these should be put at the nape of the neck, and the others against the soles of the foot, and a rapidly-interrupted current, as strong as the patient can bear, should be sent through the body for twenty minutes or half an hour. It is unnecessary for the physician to remain during this time. In some cases the electrical programme may be varied so as to get a local stimulant action from the general current. Thus, when digestion is enfeebled and the bowels are costive, for a portion of the time one of the sponges may be placed upon the epigastric region. In women, when there is great abdominal and pelvic relaxation, one pole may be placed high up in the vagina. I have seen old-standing prolapsus cured in this way.

The principle of rest-cure for the relief of exhaustion has a very wide application. Thus, in the treatment of acute diseases, such as typhoid fever, in which death results from exhaustion, it is of the utmost importance that absolute rest be prescribed very early. Before the diagnosis can be certainly established, and when there is merely a suspicion of typhoid fever developing, the patient should be put to bed, and should not be allowed to get out for any purpose. One great object of nursing is the saving of the strength of the patient and the prevention of exhaustion by disturbance. Mere uncleanness, a low voice to a deaf patient, a loud, high-pitched voice to one whose hearing is acute, failure to understand quickly the whims and caprices of a sick man or woman, are tormenting things, which may take away the rest and even destroy the life of a patient. It is almost equally essential that all fussiness be avoided. The nurse who is continually asking the patient whether he will have this or that, or wants this or that, or is shifting the blinds, or fixing the furniture, or moving about unnecessarily, may not only be disagreeable, but may do great harm.

In applying the rest-cure to the treatment of the individual case, it must be remembered that the system is based upon certain principles, and that these principles are frequently, in the individual case, best carried out by a modification of the details of the plan which I have given. Not rarely advantage is obtained by daily sending the patient out carriage-riding, or even from taking walking exercise once a day. In other cases the rest-cure may be very advantageously combined with more protracted out-door life and exercise, the patient being required simply to pass twelve, fourteen, or sixteen hours out of the twenty-four in bed and the rest in the open air. It is impossible, within moderate scope, to describe all the modifications of the method which will occur to the skilful physician.

The time of continuance of the rest-cure varies greatly: even in extreme cases the patient should be allowed to sit up at the end of

six or at most eight weeks, and in many instances three weeks of seclusion is all that is absolutely essential. The period of convalescence requires care. An attempt to return rapidly to the performance of household duties or to the ordinary labors of life will usually dissipate the acquired strength, and for the gain to be permanent it is in most cases necessary that the patient be sent to some quiet sea-shore, mountain, or country resort, in order by out-door life and gradually increasing exercise to harden into permanent form the flesh and strength which have been laboriously gathered.

TREATMENT OF CORPULENCE.

For the reduction of excessive corpulence a number of plans of treatment have been developed, many of them known by the name of the inventor or of the first patient. Among these is the so-called Bantingism, which was originated by Dr. Harvey, of London, for the relief of a Mr. Banting. The essential feature of *Bantingism* is the withdrawal of carbohydrates from the food and the living upon more or less rigidly nitrogenous diet. If the view held by some modern physiological chemists be correct, that nitrogenous food is in part so split up in the system that fat is formed from it, it is plain that even by an exclusively nitrogenous diet we do not entirely cut off the supply of fat-material; yet experience shows that in the great majority of cases under such restriction of diet the fat does disappear, and generally with great rapidity. The practical question is, however, whether the desired end is best obtained by such rigid diet; and probably few practitioners who have thoroughly tried the plan are entirely satisfied with it. It has been accused of producing Bright's disease, and it is certain that the excessive use of nitrogenous food does throw a strain upon the renal organs. This danger is, however, to my thinking, too remote to be of great practical importance, except in so far as it should lead the physician to examine occasionally the urine of the dieted patient, and, if albumen should appear, to change the treatment.

More valid objections are the chilliness and weakness from which patients often suffer although the albuminous food is allowed in large amount, and the ever-increasing repugnance to meats, which in some cases becomes almost unconquerable. This chilliness and the longing for hydrocarbons seem to be based upon an actual need of the system for fresh hydrocarbon, and Professor Voit affirms that he has seen dogs fed upon an exclusively albuminous diet perish of inanition. Moreover, in some cases of Bantingism the stomach rebels altogether against flesh-digestion, and severe dyspeptic symptoms develop, while, if there be any tendency whatever to gout, arthritic symptoms rapidly become severe. As an exclusive, final method Bantingism is not satisfactory.

A dietetic treatment of corpulence which has been much practised in Germany is that devised by Professor Ebstein, and generally known

as the *Ebstein method*. It is simply a modification of the plan employed by Dr. Harvey. Three meals a day are allowed, the routine being as follows:

BREAKFAST.—Two hundred and fifty grammes of tea without sugar or milk; fifty grammes of white bread, with plenty of butter.

LUNCH.—Fatty soup, made from a marrow-bone; one hundred and twenty to one hundred and eighty grammes of flesh, containing much fat; some vegetables; stewed fruit without sugar; two or three glasses of wine. Later in the afternoon, one cup of tea without milk or sugar.

EVENING.—One cup of tea without milk or sugar, thirty grammes each of bread and butter, one egg, or a piece of fat ham or fat roast meat, or cheese, and fresh fruit; no alcohol.

As the result of living upon this diet, Ebstein, who was his own first patient, lost in the course of the year eighteen German pounds. He states that the use of the fat produced a sense of satiety, and stilled the thirst and carbon-longing which are often so severe under Bantingism. The originality of the Ebstein cure seems to consist in the relief of the hydrocarbon appetite by fat. It is largely employed in Germany, and has even been tried with asserted good results upon animals, especially upon the pug-dogs of the German dowagers. It is stated that Vogel, in Stuttgart, reduced a dog five hundred and eighty-five grammes in a week by administering weekly three pounds of oat-meal, and at first one hundred grammes of fat, afterwards increased to one hundred and thirty grammes.

Another method of treatment of obesity which has given rise to much discussion originated with Professor Oertel, who in 1875 was in a condition of excessive corpulence in which great shortness of breath, marked failure of heart-power, inability of exertion, and increasing dropsy appeared to portend death. After failure of treatment by the most renowned physicians of Munich, Professor Oertel devised the so-called "*Oertelischen-Kur*," known more commonly, perhaps, as the "*Schweninger-Kur*." The essential features of this plan are regulation of the diet, almost complete abstention from water, and increasingly violent exercise, especially as obtained by systematic mountain-climbing.

Without discussing at present the various plans for the treatment of corpulence which have been devised, it is sufficient to draw from them the conclusion that the rational treatment of this bodily condition consists in the regulation of the diet and exercise, and that it is possible in most cases by such regulation to bring about the desired result, unless the tendency to excessive fat-production is an inherited constitutional peculiarity so strong that it can only be kept in check and cannot be entirely overcome.

The diet problem naturally divides itself into four parts for study: first, the quantity of food to be allowed; second, the relative amount of flesh, starchy hydrocarbons, and fats; third, the amount of water; fourth, the amount of alcohol.

Of those sub-problems the last is so easily and plainly solved that it may be settled at once. Alcohol is never necessary to a well-fed, healthy man. It is a pure hydrocarbon, capable of saving fat. Its excessive use, especially in the form of beer, is a common cause of corpulence, and theoretically it should be denied entirely to corpulent patients. If, however, previous habits have been such that its use cannot be stopped abruptly, it should be withdrawn as rapidly as possible. It should never be taken in the form of malt liquors, but in that of a diluted spirit or of light wine. In cases where strenuous exertion is to be made, a little sour wine added to the small amount of drink allowed the patient is often of service in alleviating thirst and in stimulating the heart.

The regulation of the quantity of food is a matter of the greatest importance, and should be attended to before anything else. In his *Advice to Fat People* (a little book published anonymously in England), a captain of a British regiment states that he had for thirty-eight years suffered from obesity, having been at birth an enormous freak of nature, clearly intended for twins. At eighteen he weighed two hundred and fifty-two pounds. Banting taught that quantity may be fairly left to the natural appetite provided the quality be strictly regarded, but the captain asserts that quantity is even more important than quality; and, acting upon this, in ten months he reduced his weight one hundred and seventeen pounds and his girth eighteen inches by adhering closely to the following dietary:

6 A.M. One pint of black coffee and one ounce of coarse brown bread or biscuit.

9 A.M. Four ounces of lean meat, three ounces of brown bread or biscuit, and half a pint of coffee.

2 P.M. Six ounces of lean meat, three ounces of brown bread or biscuit, six ounces of green vegetables, and half a pint of any fluid except ale, effervescing wines, or aerated water, followed by half a pint of coffee.

6 P.M. Half a pint of coffee.

At supper two ounces of brown bread or biscuit, and a couple of glasses of sherry or claret. Fruit *ad libitum*, liquorice powder *pro re nata*.

The average amount of food required by the human adult is generally acknowledged by competent authorities to be about as follows:

Albuminous materials.	Fat.	Starchy hydrocarbons.
30 drachms.	25 drachms.	92 drachms.

The analysis of the ration allowed Mr Banting, given by Dr. Carl Zahn, shows that he took daily—

Albuminous material.	Fat.	Starchy hydrocarbons.
43 drachms.	2 drachms.	6.26 drachms.

while the Ebstein ration contains—

Albuminous material.	Fat.	Starchy hydrocarbons.
25.6 drachms.	21.25 drachms.	11.76 drachms.

On examining the Ebstein ration it will be seen that it furnishes a much smaller amount of hydrocarbons to the system than is required for its support, so that the Ebstein method is only a mild Bantingiam. In the treatment of the individual case of excessive corpulence it is essential that the physician study the individual patient,—his present, past, likes and dislikes, constitutional tendencies, etc.,—and then prepare a special diet-list in accordance with the results of this study. General directions in regard to the amount of food to be taken are not usually sufficient when the condition of corpulence is pronounced or obstinate. The daily ration must be accurately weighed. Almost always it will be found that the patient has been eating much more than was necessary. Care should be exercised in immediately reducing the amount to the ration laid down as the average one, and as the case progresses the standard ration can be departed from in the direction of increase or diminution according to the individual needs. It is certain that some individuals require more food than do others for the support of the system, and this, independently of any question of habits of activity or of weight. The too rapid reduction of the weight is not to be desired. The aim is a moderate, steady reduction. The allowance of food should be increased or diminished according to the rapidity of the loss of weight, which should be ascertained weekly by careful weighing on the same scales, the patient being dressed in the same clothing. The ration should approximate in character that laid down by Ebstein rather than that of Harvey. Thus, there should be only a moderate reduction of the fats and hydrocarbons below the normal amount, and only a moderate increase of the nitrogenous food. When the excess of fat in the system is not very great and yields readily, it may not be necessary to weigh the food, and the partial withdrawing of hydrocarbons may be sufficient. As a foundation upon which the physician may arrange his bill of fare, the following table, originally compiled by Dr. Zahn, is appended. It gives the approximate amount of food-material in various common articles of diet in parts by weight.

Food.	Water.	Albumen.	Fat.	Hydro-carbons.
Mean of ten different kinds of simple soup	91.	1.1	1.8	5.7
Mean of ten rich soups	83.3	2.6	3.2	9.7
Boiled beef, lean, from young heifer	66.5	28.4	1.3	. .
" " fat, " " " "	49.	38.	12.1	. .
Beef from steers and oxen, boiled	56.8	34.2	7.5	0.4
" " " " roasted	59.	38.3	1.7	. .
Roast meats, including beefsteak, game, birds, etc., reckoned as an average	58.	39.2	2.7	. .
Veal, roasted	78.	15.3	5.2	. .
Fricassee'd veal, with fat and milk	57.	22.3	10.4	10.
Fat roasted pork or goose	40.	34.6	8.2	. .
Smoked ham	54.5	25.03	8.11	. .
Baked fish	74.20	22.10	0.60	5.70
Shell-fish	80.97	17.09	0.34	. .
Mean of seven different kinds of meat-foods	44.20	8.70	15.	28.9
Potatoes, roasted	72.40	1.09	2.30	21.20

Food.	Water.	Albumen.	Fat.	Hydro-carbons.
Potatoes, as salad	73.	2.10	3.20	21.80
" " boiled	70.	1.80	3.10	21.
Salad, green	91.2	1.40	2.	2.2
Vegetables in general, average*	62.2	5.40	1.40	30.
White bread	40.15	6.15	2.25	51.12
Black bread	31.	11.	..	57.
Dried fruit	1.18	13.31	3.18	81.08
Milk	87.42	3.41	3.65	4.81
Cream	65.51	3.61	26.75	3.53
Buttermilk	82.37	4.08	2.73	3.73
Butter	14.49	0.71	81.79	0.24

Sugar	2.16	2.22	..	94.52
Vinegar	91.	0.4
One egg, estimated not by percentage, but by amount in average egg	8.253	1.43	1.353	0.053
Ton	87.2	0.5	..	0.6
Coffee	94.7	2.22	0.52	1.4
" with milk	93.3	1.60	2.20	1.6
Chocolate with milk	82.	3.7	2.6	2.2

The question of the water-allowance is a serious one. The chief hardship of the dieting is, to many Americans at least, the withdrawal of the water-supply, and the patients continually ask whether water makes fat. So far as our present chemical knowledge goes, water does not make fat. Some German writers have asserted that water, by causing an increase of the blood-volume, delays circulation in the small capillaries, and thereby facilitates the change of food-fat into body-fat. This is, however, a pure theory, resting upon no established foundation, and probably incorrect. There is, in truth, no sufficient scientific reason for the withdrawal of water from the diet-list of persons who are suffering from obesity, as is well shown in a critical review on the rôle of water in nutrition by Callamand (*Archives Gén. de Méd.*, vol. xvii., 1886, 711). Nevertheless, since the days of Cælius Aurelianus (*De Morbis Chronicis*, ed. Amsterdam, 1709), in almost all the plans of reducing flesh recommended by physicians or employed by practical trainers, abstinence from water has been an important feature. This concord of practice is not to be forgotten, and it is possible that empiricism has in this direction outrun science, so that, while extreme measures seem unnecessary, it is probably in many cases essential to moderate the daily allowance of water.

When the symptoms of disturbance of the circulation are very great, and especially when the excessive drinking of beer or other liquid has caused a great excess in the bulk of blood in the body, abstention from fluids may be imperative in order that the volume of the blood may be reduced and the strain upon the circulation lessened. In Professor Oertel's case the state of affairs just spoken of seems to have existed, and it is almost inevitable that he should magnify the importance of dryness.

* Vegetables exclusively American, such as tomatoes and green corn, are not included in this analysis.

When a gouty diathesis exists, the withdrawal of water is attended with danger, an overplus of liquid being apparently necessary to wash out from the blood, through the emunctories, the arthritic products. That this danger is not a mere theoretic one is proved by the fact that Dr. Kirsch (*Lond. Med. Rec.*, August 15, 1887) has reported cases in which violent attacks of gout have followed the dehydrating treatment of obesity. He has also seen colic from gall-stones occur for the first time after such treatment, and further states that not rarely the loss of weight which he believes is produced by the withdrawal of water is accompanied by a marked muscular weakness.

The amount and form of exercise to be prescribed in any case of obesity depend upon the peculiarities of the patient and his surroundings. Certain general principles, however, apply to every case, and if these are observed the details may vary indefinitely. First, the exercise must be regular and persistent; second, it must involve not only certain muscles, but all the muscles of the body; third, it must be sufficient in amount to produce an effect,—it should always, indeed, be carried as far as is possible without the production of exhaustion; fourth, it must be sufficiently active to produce sweating, which, in many cases, may be encouraged by the use of warm clothing during exercise. Professional trainers, indeed, attach much importance to sweating as a means of reducing weight. It probably acts not only by dehydrating the body, but also by hastening the elimination of partially used-up materials, and is particularly indicated when there is any gouty tendency.

In selecting the form of exercise care should be taken that it be as little irksome as possible to the patient, and if it can be made a pleasure much will be gained. Professor Oertel, in his own case, practised mountain-climbing, and he attributes to it great superiority over other forms of exercise. There can be no disputing the effectiveness of mountain-climbing as a means of exercise. That it accomplishes, however, all that Professor Oertel claims for it is exceedingly improbable. He asserts, as the result of experiments, that mountain-climbing causes increased blood-pressure, with vascular dilatation and lowering of the arterial tension. I think that few physiologists will believe that it is possible to have increased blood-pressure with increased vascular dilatation and lowered arterial tension, the dominant factor in the production of blood-pressure being the vascular dilatation. The sphygmometer can scarcely be considered an instrument of precision. Although mountain-climbing cannot be looked upon as a specific, it is, when suitable opportunities are afforded, a very good form of exercise, because it can be so readily regulated and may be made to combine pleasure with work. At first the patient may ascend the same slope day after day, each time getting a little higher than the day before; but as the cure progresses, different excursions should be made, to add interest to labor. In America high attractive mountains are not so accessible

as in Europe, and other forms of exercise may well be substituted. A foot-exercise with whose fat-destroying tendency every trainer is familiar is running. The influence which it has upon heart and lungs does not differ from that of mountain-climbing, and, if there be any truth in the teachings of Oertel as to the value of pulmonic and cardiac gymnastics, running ought to be of especial value when the heart and lungs are giving evidences of being specially affected by the fat-accumulation. Boat-rowing, or even canoeing, may serve the purpose of the fat man. Wood-sawing is largely employed in some European anti-fat sanitariums, and is undoubtedly efficient. It can be very readily graduated by requiring one or two sticks more to be sawn each successive day. Gymnastic exercise, lifting of weights with pulleys, etc., may be employed, and even horseback-riding may be made efficient. Professor Oertel further believes that mountain-climbing affords a method of gymnastically training the heart and lungs which may be of the greatest service in the treatment of a weak heart. It must, however, be remembered that the heart is in an essentially different position from the voluntary muscle. The muscle loses its power through want of exercise, and is brought back from its soft, flaccid condition by exercise. Weakness of the heart-muscle, on the other hand, is practically never the result of lack of exercise of the heart, but is due to the accumulation of fat about the muscular fibres, or to degeneration of the muscle, to exhaustion from overwork, or to the presence of some poison in the blood. If the cardiac weakness be connected with a fatty change in the muscle which is the result of general fatty infiltration of the body, the removal of such fat-infiltration will be accompanied by improvement of the muscle of the heart, which improvement of the heart-muscle may probably be aided by cardiac exertion. If, on the other hand, the cardiac weakness is the result of overstrain or of a true fatty degeneration, the probabilities are that it will be increased rather than diminished by cardiac exertion. That these considerations are not merely theoretic is shown by the fact that Dr. Kirsch asserts (*Lond. Med. Rec.*, August, 1887) that in a number of cases he has seen violent attacks of acute exhaustion of the heart with enormous increase of the frequency and irregularity of the pulse and cardiac asthma, and in some instances even sudden death, result from mountain-climbing directed by skilful physicians in accordance with the teaching of Professor Oertel.

In all cases the exercise should at first be gentle and should be increased very carefully. Thus, mountain-climbers or runners should at first stop every few feet, to allow heart and lungs to recover themselves. It is sometimes very difficult to decide whether the heart is in a condition of fatty degeneration or simply in one of fatty overloading, and in doubtful cases the utmost caution should be exercised by the practitioner.

There are not a few robust men who have reached middle life and begun to suffer from very excessive corpulence, the result of habitual

overeating and underexercise. To such persons I can from personal experience recommend work in the wilderness, especially a tour in the Rocky Mountains or in the wilds of Canada or of Texas. If the expedition be arranged to be out for two or three months, so that the only food that can be carried is flour, coffee, and salt pork, and the horseback-riding or marching be to the limit of endurance, there will be little need of a scientifically controlled diet or of an exercise-programme. I have found that the August sun of southwestern Texas or of New Mexico is a very efficient sweat-producer, and even in the cool atmosphere of the upper Rocky Mountain regions a cure will almost always be effected. The daily labor of travelling in a canoe in a wilderness like that of Maine or Canada, the long hours of paddling or rowing, the assistance to the guides in camp-making, are in many cases sufficient to reduce the overstout man to a better condition; and if he will manfully shoulder his loads at portages, carrying packs of forty or fifty pounds through swamp or forest, up hill and down hill, for some hours daily, he will find little need to haunt sanitariums.

LITHIASIS.

Although the gouty diathesis is one of the most frequent of bodily complaints in middle-aged persons of the upper class, and an enormous amount of study and research has been devoted to the determination of its dietetic treatment, yet no positive scientific knowledge exists for our theoretic guidance. This is the fault of the pathologist rather than of the therapist. The ultimate nature of the gouty diathesis remains as much unknown as the ultimate nature of syphilis. We are therefore forced to rely upon empirical clinical experience, and even this is not yet entirely satisfactory. Thus, one of the most recent English authorities, Dr. J. Milner Fothergill, states, in speaking of the diet in chronic gout, "Fat is in all forms desirable, especially butter and bacon fat," while the German professor J. Bauer, writing in 1883, says, "In the opinion of most observers, the food of the gouty should contain as little albumen as possible, in order that the fewest products of its imperfect oxidation should be retained in the system, and also little fat, since this by fixing the oxygen would tend to hinder the oxidation of the albuminates." In the present résumé of the subject I shall avoid any theoretic discussion of the nature or causes of the gouty diathesis, as well as any statement of the opinions of authorities, and shall simply give my own views as based upon wide reading and much experience in the treatment of gouty patients.

In the hygienic treatment of gouty patients it is essential that exercise be taken systematically and with regularity. If circumstances permit, prolonged moderate exercise in the open air (such as may be obtained by horseback-riding, rowing, hunting, etc., or even by walking) is to be preferred. Gymnastic or house exercises may very well be substituted for this out-door work under special circum-

stances. The form is not a matter of much importance, provided the exercise involves the whole muscular system. The amount of exercise must be graduated to the needs of the individual case, different persons having no more the same measure of physical strength or the same needs for physical work than have different measures the same capacity. The endeavor must be always to push the exercise until it produces distinct physical weariness, and a better effect will usually be obtained if the exertion be sufficiently violent to cause free sweating. For the robust, hard muscular labor prolonged through many hours may be necessary; while in the feeblest subjects it may be essential to begin with passive exercise associated with the least possible active exercise; but day by day the physical exertion can be increased, and the results of systematic training in anæmic, feeble, gouty persons are sometimes astonishing.

Gouty patients may, for the purposes of dietetic discussion, be arranged in three classes: first, those who are robust and vigorous; second, those who with a distinct feebleness of constitution and sluggishness of habit have a marked tendency to the accumulation of fat; third, those whose nutrition and general vital forces are habitually on a low level.

In robust gouty persons it is essential that the quantity of food be lessened: such patients should be taught to rise habitually from the table with the appetite not thoroughly satisfied. In the second class of patients some control over the appetite is not rarely imperative, while in the third class of patients it is often equally essential to administer food beyond the cravings of the stomach. As individual cases occur grading all the forms of the gouty diathesis insensibly one into the other, the regulation of the quantity as well as of the quality of the food becomes a matter to be adjusted to the individual case. There are certain articles of food which should be denied to all gouty subjects. First of these in the list I would place cane-sugar. The manifest effect of overindulgence in cane-sugar in the lithæmic diathesis is probably not dependent upon any influence which it exerts on the general system, but upon the ease with which it undergoes fermentation in the alimentary canal and gives rise to acid products. Acid fruits, including the tomato and American strawberries, are also to be avoided by all gouty subjects, while non-acid fruits, if ripe, are almost invariably of great service and should be taken freely. The harm done by acid fruits is largely due to their irritant influence upon the digestive apparatus; and the suggestion of Dr. Fothergill that such fruits can be made wholesome by the addition of an alkaline carbonate is probably correct. The practical obstacle to carrying out the suggestion is the difficulty of accurately adjusting the amount of the alkali so as to avoid on the one hand lack of neutralization and on the other imparting the alkaline taste.

In gouty patients of the first class the albuminous principles of the

food should be much decreased, but clinical experience proves that the form in which the albumen is taken is not unimportant. Red meats are especially to be denied; white meats—except pork—and fish with eggs and milk are to form the main staples of animal food. The chicken is much preferable to the turkey. Game is denied by most authorities, but I have never seen any harm from its use. The waste muscle-products, such as kreatinin, xanthin, etc., have probably some connection with the injurious effects produced by red meats. If this be so, strong stock soups, which contain an abundance of these principles, ought to be injurious; and I have certainly known of violent attacks of gout apparently precipitated by the free use of beef tea, beef essence, and other similar stimulant liquids. If soups, therefore, are employed, they should be vegetable rather than stock soups. Ordinary carbohydrates may be taken in moderation. Green vegetables, including roots, are especially serviceable.

The proper dietetic treatment of anæmic gouty subjects distinctly inclined to corpulence is a matter of difficult determination. The first thought would lead the physician to order a reduction in the habitual ingestion of albumen; but I have certainly known very good results produced in patients of this class by lessening very decidedly the carbohydrates in the food. When this is done, the albuminous ingestion must be increased rather than decreased, in order to support the system. In many of these cases, however, it will be found that the patient habitually takes an overplus of food, and much good may be achieved by lessening the quantity: in such patients the carbohydrates can be largely withdrawn and the habitual ingestion of albumen not increased. It is especially in patients of this class that the sagacity of the physician in modifying the diet to suit the needs of the individual will meet with reward. My own plan has been in doubtful cases to make tentative alterations of the diet,—to regulate the quantity of food, withdraw carbohydrates, and order the albuminous nourishment to be taken chiefly in the form of fish, white meats, eggs, and milk. If the patient improve, the diet is evidently suitable for the individual case; if there be no improvement, or if there be aggravation, the diet can be at once altered.

In anæmic, impoverished, gouty subjects the best results are not rarely to be achieved by the employment of generous diet combined with the moderate use of alcoholic liquors. In selecting the drink, malt liquors and acid wines are to be avoided. My own experience is that diluted spirits offer the best form for the administration of alcohol.

In any obstinate gouty case which fails to yield to the ordinary regulation of diet the so-called *milk diet* should be tried. It is not at present possible to give any sufficient scientific reason for the alterations which are occasionally produced in diseased human systems by the exclusive milk diet. The whole story of changes wrought by the milk diet

in nutrition we do not know. It evidently, however, has a pronounced influence upon primary digestion in the intestinal tracts. It offers organic principles in so simple a form as to reduce to the minimum the labor of digestion, and probably to relieve greatly the hepatic and other similar glandular organs from excess of labor. By virtue of the large quantity of water it contains it enormously increases the flow of the urine and probably of the secretion of the skin, and in some cases is no doubt of great service in washing out excrementitious material from the body. Whatever may be the proper scientific explanation of the fact, it is certain that in some cases of gouty diathesis and in various other abnormal conditions of nutrition an exclusive milk diet is extremely beneficial. Thus, in fatty anæmic subjects a course of two or three weeks of milk diet sometimes alters the nutrition so that afterwards feeding and tonics produce effects which were previously not attainable. I have always suspected that in these patients there is an underlying gouty diathesis. I have seen cases of gouty disease of a chronic and subacute type in which remedial measures had entirely failed, but which yielded easily, though slowly, to an exclusive milk diet. Very frequently when it is simply intended to fatten the patient, or in the combating of the gouty diathesis, milk is given largely with other food; but to get the peculiar full effects of a milk diet it is essential that the patient abstain at least for a time from all other food. After the first two or three weeks stale bread may be allowed, then green vegetables, and slowly the patient may thus be restored to ordinary diet. In severe cases, however, milk diet may be persisted in for weeks, and it is possible for the human adult to work laboriously and live exclusively upon milk. In order to afford sufficient nitrogenous nutriment, from five to seven pints of milk a day must be taken. This amount of milk contains too much fat for the needs of the system; it should therefore be skimmed. The so-called skimmed milk sold from creameries is not, however, suitable, because the fat has been too absolutely withdrawn from it, and because it is usually not so fresh as is desirable. The skimming of the milk should not be too close. It is essential that the milk be taken at intervals of not longer than two hours, and that it be drunk by sipping rather than by gulping, so as to avoid any danger from the formation of hard clots in the stomach. When the digestion is good the milk may be taken cold. When the digestion is very feeble it should be taken hot. But boiled milk should not be employed, as, according to the experiments of Drs. Randolph and Dixon, it is of more difficult digestion than unboiled milk. The general clinical experience shows that it is more actively constipating than unboiled milk. During the progress of the milk course constipation is almost invariably present: this must be overcome by the administration of drugs. In gouty subjects saline laxatives are preferable.

CHAPTER III.

CALORIC.

THERE are two conditions of the force caloric, spoken of as distinct entities, but which are merely relative terms, expressive of the presence of an excess or of the absence of the normal amount, or, more strictly speaking, normal intensity, of the force. Cold and heat, in connection with the human body, respectively mean an intensity of caloric below and above $98\frac{1}{2}^{\circ}$ F.

USE OF HEAT.

The phenomena of death from cold show that a lack of caloric in the body is no less paralyzant of animal functions than is an excess of the same force. Evidently the organism was constructed to run upon a certain plane of heat, and cannot vary from this without serious results. By numerous experiments upon animals I have proved that in a cool apartment death rapidly results after section of the spinal cord, from falling of the bodily temperature, the animal which in a warm room will live indefinitely dying very shortly in a temperature of forty degrees. The cause of the inability of the animal to resist external cold after section of the cord is undoubtedly vaso-motor paralysis. Normally, the temperature of the interior of the body is maintained by keeping an outer layer of partially-cooled tissue between the internal organs and tissues and the outer air. When the power of contracting the superficial vessels has been lost, the organism can no longer maintain this protecting layer, the surface-temperature rises to that of the interior, heat is rapidly lost, and the whole body is uniformly cooled.

Vaso-motor paralysis is produced by toxic doses of various remedies, and under these circumstances artificial maintenance of the bodily temperature is imperative, forming a very important portion of the treatment of all such poisoning. Collapse from any cause is largely dependent upon, or, more correctly speaking, largely is, vaso-motor palsy; hence in almost all forms of collapse the use of external heat is of great importance.

The late Dr. Chas. Hunter very successfully applied this treatment to that form of collapse which follows injuries and surgical operations and is known by surgeons as *shock*. The lack of power of alcoholic and other ordinary stimulants in this condition is proverbial. The

pathological state is undoubtedly vaso-motor palsy, the bodily temperature is much below normal, and the rational treatment consists in the hypodermic use of atropine and digitalis and the external employment of the hot bath. I believe that this plan of treatment will be found to be a most important addition to surgical therapeutics. In the first days of post-fœtal life the power of resisting external cold is very slight, and in many cases of still-born children, or of children whose vital powers are almost extinguished at birth, life may be saved by a high external temperature, the little waif being kept in an air of 98° F., and also away from the influence of cold walls and articles which would draw off, as it were, the slender store of heat provided by nature, radiation being greatly affected by the temperature of surrounding objects.

It is hardly necessary to dwell in greater detail upon the various forms of collapse. Enough has been said to illustrate the principle that *whenever the bodily temperature falls below normal, pyretic treatment is demanded*. The vigor of the treatment should always be in direct proportion to the suddenness and extent of the fall of temperature.

In regard to the methods of applying heat, it must, in the first place, be understood that wrapping in blankets, etc., is able only to prevent cooling of the body; that when the animal temperature has already fallen it will not suffice at all. The same may be said of air heated to temperatures which can be readily obtained or can be continuously borne by the attendants. Radiated heat is somewhat better, and often the use of a brisk open fire is of service. The *hot bath* is, however, the only pyretic remedy that can be relied on. It should always be a full bath, in as warm a room as can be procured, and should be at a temperature of about 104° F. when the patient is put into it. The duration of the bath must vary with the circumstances of the case. It should not be less than half an hour, unless the mouth-temperature sooner become normal. During the bath the heat of the water should steadily be increased as fast as it can be borne if the patient be conscious, or, if he be unconscious, until a temperature of 110° F. is reached.

USE OF COLD.

The practical study of the use of cold as a therapeutic measure naturally arranges itself under three divisions: first, its local use; secondly, its very brief general application as a tonic; thirdly, its employment in pyrexia.

LOCAL EMPLOYMENT OF COLD.

When cold is applied persistently to any part, it acts as a direct and very powerful depressant, of varying power according to its intensity. It is, therefore, used locally to reduce *inflammation*, especially when the latter is of an active type. In this employment of cold, care must be

exercised not to carry its use too far, lest it suspend all nutritive actions and interfere with those processes of repair which almost always form a part of inflammation. Indeed, it is possible to convert an inflammation into gangrene by the too energetic employment of this agency. Locally, cold is generally applied by means of cold-water compresses, irrigation with cold water, and the application of pounded ice, either enclosed in india-rubber bags or in bladders, or in form of the *ice-poultice*.* It is very doubtful whether the use of "freezing mixtures" is ever justifiable in inflammation. The effects of the cold in individual cases are to be judged of by the alterations in the heat and redness of the part. The local employment of cold belongs for the most part within the province of the surgeon, but the remedy is of great value in certain diseases. In *diphtheria* and in *anginose scarlatina*, as originally insisted upon by Dr. Hiram Corson, very great benefit may be obtained by enveloping the throat over the tonsils with powdered ice enclosed in bladders, in pieces of pigs' intestines such as are used by sausage-makers, or in thin india-rubber bags.

In using cold for the purpose of combating inflammation, the application must be kept up until the desired effect is produced. When employed intermittently, cold even becomes a stimulant, the reaction which follows its first impression being greater than its direct effects. Hence the cold douche has been used with asserted advantage as a stimulus to *sluggish ulcers*.

In internal trunkal inflammations, such as *pneumonia* and *pleurisy*, the application of cold wet compresses over the diseased organ has been employed extensively in Germany. In the hospital at Prague every patient suffering from acute pulmonic inflammation is said to be treated with cold compresses, and Smoler affirms that it is very rare that immediate relief is not afforded. Niemeyer states that he has employed the method in a large number of cases of pneumonia with surprisingly good effect, the pain, the dyspnoea, and even the frequency of the pulse being usually reduced in a few hours. On the whole, the evidence in favor of the local use of cold in pneumonia, as well as in the croupous catarrhal pneumonia of children (Bartol, Ziemssen), is so strong that the repugnance felt to such measures by the profession in the United States would seem to be the offspring of unfounded prejudices.

In *meningitis* the great value of the application of ice to the shaven scalp is undeniable, and in *peritonitis* I have seen very great relief afforded by the use of cold, as recommended by Abercrombie, Niemeyer, and others. As is the case in pneumonia, warm poultices are more generally viewed with favor in peritonitis by the profession in this country. I have frequently used them with excellent effect, and in at least one instance after ice-poultices had been previously em-

* Made by mixing finely-broken ice with dry Indian meal or fine sawdust.

ployed. In this case the cold applications were at first very agreeable to the patient, as were the warm poultices afterwards, and the good achieved seemed to be in accord with the sensations of the patient. It seems to me a good clinical rule to select the ice or the warm poultice according to the feelings of the patient. Early in the attack, when the fever is high, the ice will generally be the more useful.

Under the head of the local action of cold it is perhaps proper to allude briefly to the use of the cold douche as a means of reducing *splenic enlargements*. I have had no experience with the measure, but an elaborate experimental and clinical study has led Dr. Fr. Mosler to the following conclusions. In the spleen immediate contact with cold water produces a very perceptible contraction, which is in direct proportion to the coldness of the water; the application of cold water to the abdomen influences similarly but less efficiently the normal spleen; the cold douche applied for two or three minutes, and repeated at longer or shorter intervals, very perceptibly affects the enlarged spleen of intermittent and typhoid fevers, and even of leukaemia. In chronic cases the application should usually be made twice a day. (*Virchow's Archiv*, Bd. lvii. p. 1.)

COLD AS A TONIC AND STIMULANT.

Almost every one has experienced the exhilaration of the reaction which, in a healthy person, follows the sudden dash of a cold shower-bath or the plunge into a mass of cold water. The researches of Liebermeister, which will be detailed hereafter, prove that a cold bath, when of not too long duration, actually increases the oxidation of tissue to such a degree as to elevate the temperature of the body. When cold bathing is employed as a tonic, the first principle to be borne in mind is that the bath should not be too severe or too long continued, else it becomes a direct depressant, debilitating and lowering the temperature of the bather. When the subject has sufficient vital power to react after the bath, sea-bathing is often of very great service, but in debilitated persons it may produce a serious exhaustion, partly by the fatigue induced, and partly by the excessive abstraction of heat from the body. The cold bath, when not followed by a healthy reaction, is anything but a tonic.

COLD IN PYREXIA.

The use of cold in fever is no new thing: employed by Galen, used not infrequently during the last century, first systematized and insisted upon by Currie, cold bathing in fever was brought before the world as a really new-born measure by Brandt of Stettin, and received the seal of permanent usefulness from the scientific clinical labors of Jürgenson at Kiel.

The consideration of the method naturally divides itself into—first, a study of its physiological action; secondly, an investigation as to its clinical value; and thirdly, a more particular account of its effect, the cases to which it is best adapted, and the method of its application. Moreover, there are two distinct forms of pyrexia, which may be termed the acute and the chronic, and which are best considered separately.

ACUTE PYREXIA.—If the following propositions be true, caloric in an excess acts as a direct poison to the body, and the phenomena of severe acute fever are largely due to the heat itself. The proofs of the propositions are given very briefly after them.*

First. External heat applied to the body of the normal animal, so as to elevate the temperature, produces derangement of the nerve-functions, of circulation, etc., precisely similar to those seen in natural fever; the intensity of the disturbance being directly proportionate to the rise in temperature.

Second. Heat applied locally to the brain or to the heart produces in the functions of the organ those disturbances which are familiar phenomena of fever, the intensity of the disturbance being directly proportionate to the excess of heat in the organ.

Third. The withdrawal of the excess of heat in fever is followed by a relief of the nervous and circulatory disturbances.

When a dog, cat, or rabbit is shut up in a box heated either by the sun's rays or by artificial means, the temperature of the animal rises, and at the same time the pulse-rate becomes *pari passu* more rapid, the breathing grows more and more hurried, and the restless, uneasy movements of the victim show the general distress it is suffering. As the temperature increases, the nervous disturbance becomes more and more apparent; and stupor, coma, partial paralysis, convulsions, and finally death by arrest of the respiration, occur. These phenomena sometimes come on gradually, but sometimes are developed suddenly. The temperature at which death occurred in my experiments varied in the rabbit from 111° to 114° F.; in the dog it was about 111° F. In man a similar series of phenomena are developed by exposure to excessive heat, although, owing to his extraordinary power of cooling his body and of protecting it against cold, he is able to bear extremes of temperature far beyond the points which would prove fatal to any given species of animals. Yet when his body is heated the results are the same, as is proved by the terrible mortality of sunstroke.

To prove the second proposition, I caused hot water to flow through pigs' bladders fitted as a sort of bonnet to the heads of cats and rabbits. It is evident that with small animals we can in this way heat the brain without heating materially the remainder of the body. It was found

* Want of space prevents the elaboration of this. The unconvinced reader is respectfully referred to the author's treatise on Thermic Fever, and his Toner Lecture on Fever.

that coma, with or without convulsions, was produced. Sometimes the stupor came on gradually, hebetude slowly deepening into coma, but in other instances unconsciousness was developed very suddenly. It was found that severe nervous symptoms and death were produced when the brain reached the temperature which was fatal to the animal in the hot box. Without occupying more space, the conjoint labors of Dr. T. Lauder Brunton and Dr. C. Liebermeister have proved that the accelerated pulse in fever is largely due to the action of the heat upon the heart and its nerves: so that the second proposition may be considered demonstrated.

In regard to the third proposition, I have frequently taken animals out of the hot box perfectly unconscious and plunged them into a bucket of cold water, have watched the temperature of the water rise while that of the animal fell, and as the bodily heat came towards normal have seen the coma disappear, so that within ten minutes the at first absolutely comatose and dying rabbit would be skipping about on the grass. I have placed a man whose temperature was nearly 110° F., who was unconscious, with a feeble running pulse of 160 or 170, irregular, jerking, slow respirations, and every indication of immediate death, in a bath of 60° F., and within a minute and a half have seen consciousness partially restored, and in another minute and a half the man trying to get out of the bath. What could the bath do to affect the man so profoundly and so quickly but withdraw the heat? That the heat was present, and that it was withdrawn, the thermometer proved. If the drowsiness had been due to simple congestion of the brain, very certainly would the bath, by driving the blood from the surface, have increased the trouble. It must be borne in mind that this case is by no means unparalleled: similar instances of the good effects of the sudden withdrawal of heat in rheumatic hyperpyrexia have been recorded by both English and German observers, and recent Continental literature is full of reports of the relief of nervous symptoms in various pyrexias by the abstraction of heat.

Finally, as excessive heat is present in fever, as excessive heat, when present, is not only able, but is forced, so to speak, by its own attributes, to produce disturbance of the functions of innervation and circulation, and as the withdrawal of the excessive heat in fever is followed by instantaneous relief of the symptoms of disturbed innervation and circulation, surely the conclusion is logically inevitable that excessive temperature is the chief cause of the other symptoms of fever, and that in *acute pyrexia* threatening life the heat should be withdrawn as rapidly as possible by means of the cold bath.

Chronic Pyrexia.—The effects of a long-continued pyrexia, not sufficiently intense to induce immediate serious symptoms, upon the structure of the various tissues, have been elaborately investigated by Liebermeister (*Deutsches Arch. für Klin. Med.*, Bd. i.), who found that the liver, spleen, kidneys, voluntary and involuntary muscles, blood-

vessels, and even the nerve-centres, undergo a granular degeneration during a continued pyrexia. The lesion was constantly present in the bodies of those who had suffered in this way during life, entirely independently of the nature of the primary disease. In cases of infectious fever in which the temperature had never been high, this granular degeneration did not exist. Previous to the investigation of Liebermeister, Zenker had demonstrated that the muscles undergo a peculiar granular degeneration in typhoid and other fevers; and the fact has been abundantly attested by later observers. I do not know that the observations of Liebermeister as to the occurrence of this lesion in non-infectious pyrexia have been confirmed, but I have no doubt of their correctness.

It is evident that in all fever a primary therapeutic indication is to reduce the temperature. Of course, if possible, this should be done by checking the excessive production of heat; but, unfortunately, this often lies out of our power, and we are forced to abstract the heat by mechanical means.

It is *a priori* impossible to determine what effect upon the production of heat the rapid abstraction of it would have, but, from the well-known powers of the organism to resist external cold, it seems probable that the heat-production would be increased rather than diminished by the abstraction of caloric. An experimental study of this problem has been made by several observers, but with, unfortunately, different results. Weisflog (*Deutsches Archiv für Klin. Med.*, Bd. ii. p. 570) has found that the local abstraction of heat by a cold sitz-bath causes a rise in the temperature of the axilla, and that in fever-patients, unless the sitz-bath is prolonged over twenty minutes, no fall of the bodily temperature results. In 1860, Kernig (*Reichert's Archiv*, 1860) found that a healthy man in a bath of the temperature of 28° to 30° C. produces about twice as much heat as normal; in a bath of 24° C., about three times as much; and in a bath of 20° C., about four times as much. Liebermeister (*Beobachtungen und Versuche über die Anwendung des kalten Wassers bei fieberhaften Krankheiten*, Leipzig, 1868) found that in a healthy man exposure to cold for a brief period of time causes a rise in the bodily temperature, and on extending his researches into fever proved that where the external cooling was not too powerful or too long continued the same was true of fever-patients. From this it follows that the use of external cold stimulates heat-production. This, to my mind, has been confirmed by the chemical researches upon men of J. Gildemeister (*Virchow's Archiv*, Bd. lii. p. 131), of Dr. Lehmann (*Ibid.*, Bd. lviii., 1873), and of Professor Liebermeister himself (*Deutsches Archiv für Klin. Med.*, Bd. x. p. 89), and by those of A. Roehrig and N. Zuntz (*Pflüger's Archiv*, Bd. iv. p. 66) upon animals, all of which show that both in health and in fever very much more carbonic acid than normal is eliminated under exposure to cold. This would appear to prove that cold baths increase the production of

animal heat. It seems most probable that this is the case; but A. Murri believes that he has proved that the cold baths have no such influence.* At any rate, the investigations of Liebermeister (*loc. cit.*, p. 134) and others have shown that the first rise of temperature produced alike in healthy and in fever subjects by exposure to a moderate and not too long continued cold is followed after removal of the cold by a fall of bodily temperature of greater or less degree. While, therefore, external cold probably first stimulates, it afterwards depresses the production of animal heat. The further experiments of Liebermeister (*Deutsches Archiv für Klin. Med.*, Bd. x. p. 425) upon the elimination of carbonic acid are also in accord with his temperature-study, for he found that after the bath the elimination sank below normal, and so continued for a considerable period.

If the cold bath really affects the fever-process, it ought distinctly to reduce the excretion of urea. That it has this action would seem to be proved by the research of Sassetzky (*Virchow's Archiv*, xciv. 517), who found that the continuous use of the cold bath invariably lessened the urinary elimination of nitrogenous material and of the phosphates, although it increased the total flow of urine. The subject is, however, a very difficult one, chiefly because it is almost impossible to know in any individual case what the elimination of urea would have been if no baths had been used. Bauer and Künstle (*Deutsches Archiv f. Klin. Med.*, xxiv.) gave to the patients cold baths upon alternate days, and found that the excretion of urea was in each case greater on the days when baths were used than on those on which they were not employed. These experiments have been quoted as showing that the cold bath increases the excretion of urea, but in Schleich's investigations on the effects of hot baths (*Archiv f. Exper. Path.*, 1875) the increase of the excretion of urea frequently did not show itself until the day after the bath. It is probable, therefore, as believed by Schleich, that the destruction of albuminous substance in the tissues is not manifested in urea-elimination until after twenty-four hours, or, in other words, that twenty-four hours are necessary for the completion of the formation and the excretion of urea; so that if the baths are used on a Monday the urinary solids will indicate their effects not on the same day but on Tuesday. If this be correct, the experiments of Bauer and Künstle are in accord with those of Sassetzky in showing that the cold bath lessens the formation of urea in fever.

During the bath the pulse of the fever-patient usually becomes much smaller and harder, and the sphygmographic tracings made by Winternitz before and after the use of the cold bath (if tracings of this kind can be trusted) indicate that there is after the cold bath greatly increased arterial tonus. (See *Verhandl. des Congr. für Innere*

* I have never seen the brochure of A. Murri (*Del Potere regolatore della Temperatura animale*, Firenze, 1873). It is abstracted in the *London Medical Record*, vol. L.

Med., 1886.) It may be that the good obtained by the cold bath is really due to a reflex action upon the nerve-centres, and is not entirely the result of the withdrawal of the heat.*

The results of the physiological study of the effects of cold in fever may be summed up as follows: *During a sufficiently prolonged application of cold the bodily temperature falls, although an increased production of heat, i.e., consumption of tissue, at first occurs. After the application, the bodily temperature continues to fall, or but slowly regains its former position: the present evidence at our disposal indicates, but is not sufficient to prove, that this slow regaining of bodily temperature is due to a diminished production of animal heat,—that is, to a decrease in the waste of tissue and in the formation of urea and carbonic acid.*

The clinical evidence in regard to the use of cold in fever may be looked at in two different ways. Thus, we may consider the assertions and results of individual observers who have seen large numbers of cases and used the method faithfully, or we may weigh the sum total of the experience of all who have written upon the subject. At first sight it may appear that the latter is by far the best course to pursue; but it must be borne in mind that the treatment is one opposed to the ordinary medical prejudices, that its efficient carrying out involves so much labor and attention as to be almost impossible to those who disbelieve in its usefulness, and that those physicians who claim most for the method affirm most strongly that to do much good it must be practised very vigorously and steadily. These things being so, it seems wisest to look at the evidence from both points of view, and I shall first tabulate all the statistics I have been able to collect and afterwards discuss the statements of individual observers.

* Naunyn (*Archiv f. Exper. Path. und Pharm.*, Bd. xviii., Heft 1 and 2, 1884), indeed, recently denies that the good achieved is due to withdrawal of heat at all. In his experiments he found that if he maintained proper ventilation, carefully giving food and water, he could gradually heat rabbits up to the temperature of 107° and 108°, and keep them at this temperature for weeks without their evidencing any inconvenience and without the production of any internal lesions. Krishaber was also able to maintain in a dry room 117° F., his own temperature reaching 107°, pulse at 85, respiration 35. Naunyn is a very strong advocate, as the result of his experience, of the employment of frequent baths in the treatment of fever, but believes they act by indirectly reducing bodily waste and increasing renal secretion, strengthening the pulse, and stimulating the nerve-centres. L. Schweinburg and C. Pollak (*Centralbl. f. Germ. Therap.*, March, 1887) have found in a series of apparently very careful experiments that cold hip-baths notably increase blood-pressure and lessen pulse-rate, while hot hip-baths had the opposite effect. Naunyn believes that better results are obtained from the use of constant lukewarm baths than from the employment of excessively cold baths. In very severe cases, marked by dicrotic pulse and disturbance of the sensorium, the bath treatment, according to Naunyn, should be commenced before the axillary temperature reaches 103° F., and frequently a warm bath may in such case be given between two cold baths. Such a treatment is especially indicated when there is marked delirium, tremor, subsultus tendinum, or great restlessness; a warm bath in the evening then seldom fails to produce some favorable result.

TABLE SHOWING THE RESULTS OF THE COLD-WATER TREATMENT IN TYPHUS AND TYPHOID FEVER.

Name of Reporter.	Place.	Number of Cases.	Mortality, Per Cent.	Remarks.
Jürgensen.	Kiel.	160	3.1	Previously 15.4 per cent. Typhoid fever.
Petri.	Laubbach.	31	3.2	
Liebermeister.	Basel.	1121	6.2	Previously 26 to 30 per cent. Treatment very rigorous. Typhoid fever.
Mosler.	Greifswald.	71	7.	
"	"	92	7.	Typhus exanthematicus, previously 50 (?) per cent.
Becher.	Ostpreussen.	17	24.	Typhus exanthematicus, previously, on an average, 10 per cent.
Brandt.	Stettin.	479	3.5	Private practice.
Goden.	"	24	20.0	
Stohr.	Würzburg.	178	0.6	Previously over 20 per cent.
Drasche.	Vienna.	40	10.	Year before 16.5 per cent.
Ziemssen.	Erlangen.	32	9.4	Formerly, with bad cases, 30.2 per cent.
Stieler.	Munich.	226	5.6	Formerly 12.15 per cent.
Pastau.	Breslau.	246	11.8	Typhus exanthematicus. Without baths, mortality 16.5 per cent.
Popper.	Prague.	20	5.	
Riegel.	Würzburg.	156	4.4	Only serious cases included. Almost every fatal case came in too late for baths to do good.
Göts.	Prague.	54	5.5	Typhoid fever. Other cases treated at the same time, expectantly, 15.4 per cent.
"	"	50	15.8	Typhus exanthematicus.
Scholz.	Bremen.	125	4.	Typhoid fever.
Wunderlich.	Leipsic.	155	7.	Typhoid fever. Previously 18.1 per cent. out of 1178 cases.
Zaubzer.	Munich.	356	5.6	Typhoid fever. Previously 17.6 per cent. out of 701 cases.
Bauer.	"	87	7.	Typhoid fever. Previously 11½ to 16 per cent.
Duchek.	Vienna.	50	28.0	According to Brandt, this high mortality depended upon the treatment having been imperfectly performed.
Kroft-Ebing.	Rastatt.	105	25.7	Only bad cases. Previous mortality 34 per cent.

Böhm.	Niederbrunn.	131	11.5	Typhoid fever. Military hospital.
Gersauer.	Vigy.	97	0.10	Typhoid fever. Mortality on expectant treatment 23.91 per cent.
Drasche.	Vienna.	55	19.	Typhus fever.
Merkel.	Nuremberg.	41	2.1	Typhus fever.
Loebel.	Vienna.	87	18.4	Typhoid fever.
"	"	105	22.6	Typhus fever. The treatment in this and in the preceding case was not thoroughly carried out; the patients mostly receiving only three baths a day.
Glénard.	Lyons.	52	5.	Typhoid fever.
Schmidt.	Erlangen.	56	0.18	Several fatal cases not counted, because not received until the fifteenth day, and, therefore, too late to test the treatment; they bring the total mortality to 4.14 per cent.
Heubner.	Leipsic.	72	0.14	
Bins.	Versailles.	190	2.1	Soldiers. Mostly, if not all, typhoid fever.
Zeroni.	Mannheim.	72	18.	Soldiers.

TABLE SHOWING THE RESULTS OF THE COLD-WATER TREATMENT IN TYPHUS AND TYPHOID FEVER.—Continued.

Name of Reporter.	Place.	Number of Cases.	Mortality, Per Cent.	Remarks.
Valette.	Lyons.	21	0.	Typhoid fever.
Edes.	Boston.	32	2.75	Typhoid fever.
Jürgensen.	Tübingen.	220	1.8	All after this in the table are taken from Brandt's article in the <i>Deutsches Med. Wochenschrift</i> , 1887.
Vogt.	Munich.	271	2.7	
Tripier and Houvet.		481	0.	
		2081	7.4	
In German Military Hospitals.	1877.	2112	8.9	
	1878.	1741	9.4	
	1879.	2534	8.9	
	1880.	477	8.8	
Ibid. Second Army Corps.	1882.	429	8.8	
	1883.	392	3.5	
		188	3.1	

This table is of such a character that a lengthy discussion of it would be unnecessary and unprofitable. The failure at Vienna is, by the upholders of the method, very justly attributed to an inefficient carrying out, while the apparent high mortality in some other instances is due to the facts that the reporters included none but the most serious cases, or that the patients were soldiers worn out by the hardships and toils of a severe campaign. Moreover, in many cases the cold-water treatment was probably not sufficiently rigorous. Dr. Ernest Brandt has made a collection of nineteen thousand and seventeen cases of fever in which the antipyretic treatment was carried out with more or less care, the average mortality being 7.8 per cent. In this mass are included typhoid and typhus fever with all forms of primary and secondary complications, occurring in all ages, in both sexes, in epidemics and in isolated cases, in hospital and in private practice, in civil and in military life, during war and during peace. Brandt very forcibly objects to these statistics as not fairly representing the results of a stringent antipyretic treatment, because in many instances the treatment was not carried out with rigor, and often it was not begun before the last stages of the disease. He has made a second series of statistics, including five thousand five hundred and seventy-three cases, in which the treatment was under the direction of a physician who had confidence in it: the mortality is 3.9 per cent. These statistics are upon so enormous a scale that if it be possible to demonstrate by statistical arguments the results of any method of treatment whatever, it must be considered proved that the cold-water treatment of the continued fevers is attended with a remarkably small percentage of deaths.

If instead of studying the subject in these marred statistics the evidence furnished by single observers in favor of antipyresis by cold be

examined, the results are even more positive.* It is stated by Winternitz (*Verhandl. des Congr. f. Innere Med.*, 1886, 5) that in the French and Austrian armies the antipyretic treatment of cold has not been employed, while in the German army it is practised more or less zealously. The mortality in the French army averages 36.9 per cent., in the Austrian 27.4, and in the German only 9.6. That this decreased mortality is due to the antipyresis seems to be established by the fact affirmed by Brandt, that in the Second German Army Corps, in which the treatment is carried out more thoroughly and systematically than in the other corps, the mortality is less than four per cent., and that, too, in the face of the fact that in the same hospitals, from 1849 to 1856, the mortality was twenty-six per cent. Jürgensen states that from the year 1850 to 1861 there had been treated in the hospital at Kiel, according to the expectant method, three hundred and thirty typhoid fever patients, with a mortality of 15.4 per cent.; while from 1863 to 1866, during which period the antipyretic method was employed, in one hundred and sixty cases the mortality was 3.1 per cent. Professor Liebermeister has employed the cold-water treatment on a larger scale than has any other individual. At the hospital at Basel, up to the year 1865, one thousand seven hundred and eighteen cases of typhoid fever were treated upon the expectant plan, with a mortality of 27.3 per cent. In 1865, Dr. Liebermeister introduced the use of cold bathing in a timid, inefficient manner, and reduced the mortality, in nine hundred and eighty-two patients treated, to 16.2 per cent. In 1866 he began the vigorous regular employment of the method, and reduced the death-rate, in one thousand one hundred and twenty-one patients treated, to 8.2 per cent. Professor Liebermeister himself criticises very closely, in Ziemssen's "Encyclopædia of Medicine," these statistics, and raises the mortality, by excluding trifling cases, to from ten to eleven per cent.; but, after the antipyretic treatment has been even unjustly dealt with, the statistics still show that the mortality under the cold-water treatment is not half what it formerly was. Further, a certain proportion of cases are always admitted to the hospital moribund, too late for any human agency to be of avail: these cases, of course, maintain the same proportion under any treatment; they really constitute a large part of the deaths seen in the cold-water treatment, so that if they were eliminated from both sides the death-rate "under the antipyretic plan would be but a small fraction of what it would be under the other."

In hospital practice the patients are very rarely received upon the first day of the attack, and very frequently do not enter the wards

* M. Franz Glénard affirms (*Glasgow Med. Journ.*, 1874) that there have been from six thousand to eight thousand cases of typhoid fever treated by the use of cold in Austria, Prussia, and Russia, with an average mortality of from 4.5 to 7.6 per cent.,—the previous mortality under the old expectant method having varied from eighteen to twenty-five per cent. If these figures be correct, they are decisive. Where M. Glénard gets them from, however, I do not know.

until the third week, so that the statistics, as already intimated, favorable as they are to the new treatment, express only a portion of the truth. If the good effected be so great when the remedy is often not applied until the second or third week, much more is to be expected when it is employed faithfully from the moment the temperature becomes elevated.

All those physicians who advocate the use of cold baths in typhoid and typhus fevers appear to be agreed that, although the mortality is very much reduced, the duration of the disease is shortened only in so far as complications are avoided. As, however, the patient is left by the disease much stronger than he is when the expectant method of treatment is pursued, convalescence is much more rapid than under the old plans. By the antipyretic treatment the intense prostration, delirium, stupor, carphologia, involuntary passages, and other manifestations of the typhoid state are greatly lessened. The relief afforded is so evident to both patient and attendants that they usually, after one trial, acquiesce in the regular employment of the cold baths, although to the one the sensations are at first very disagreeable, and for the other the labor and attention required are very much increased. The antipyretic use of cold in typhoid fever has not, however, been free from determined opposition (see discussions in *Le Progrès Méd.*, 1877; also *Bull. Thérap.*, xci.), and the assertions in its favor are some of them evident exaggerations. I am, however, thoroughly convinced by my own experience, as well as by the great mass of recorded evidence, that the treatment of typhus and typhoid fever by cold is of the utmost value, and I believe that the cold bath is *much safer and more efficient than are antipyretic drugs*. In America the method has met with comparatively little favor, chiefly because of the labor it involves and of the prejudice of the laity. I have no doubt that very many persons have died in the United States of typhoid fever whose lives would have been saved if the American medical profession had risen above the opposition of the laity and above its own prejudice.

A very practical question, but one which we are as yet scarcely in a position to answer fully, is, What are the contra-indications to the use of cold in fever? According to our old ways of thinking, bronchitis and pneumonia would especially seem to be in the way. The serious lung-affections of low fevers are, however, largely dependent upon the general adynamia, and this adynamia is, in turn, largely the result of the excessive temperature. Accordingly, the German investigators have not found the baths to do harm in the pneumonias of exanthemata. Liebermeister, who has had more experience than any other observer, says that "pneumonia, hypostatic congestion, and the like, offer no reason for suspending the baths: the hypostatic troubles sometimes disappear under their use." I have carried one or two cases, in which the lung-symptoms were very severe throughout, to a successful issue, employing cold freely, and was unable to perceive any evil effect upon

the lungs. Prof. Raynaud, as the result of his experience, affirms emphatically that neither pulmonic nor intestinal complications should interfere with the use of the cold bath (*Bull. Thérap.*, xci.). On the other hand, Proust reports (*Ibid.*, xcii.) two cases in which fatal pneumonia of the ordinary type, not the hypostatic pneumonia of advanced fever, was apparently produced by cold baths. Dr. Alix also reports two deaths from pneumonia in three cases in which he tried the baths. My own feeling is that severe bronchitic or pulmonic symptoms occurring in the *beginning* of typhoid fever should make us very cautious in using the antipyretic method, but that when they occur late in the fever, and are due rather to hypostasis than to inflammation, they are not contra-indications to the use of the bath. Professor Liebermeister affirms that perforation of or hemorrhage from the bowels is a contra-indication to the use of cold in fever, because cold has a tendency to produce determination of blood to the internal organs. The experience of Wunderlich (*Schmidt's Jahrbücher*, Bd. clvi. p. 101) is, however, very much opposed to this idea of Liebermeister's. He treated sixteen cases of severe intestinal hemorrhage with cold baths, with but two deaths,—neither of which resulted directly from the hemorrhage, one being from intestinal perforation and one from severe pneumonia. This mortality is certainly a very small one, for when cold water was not employed, out of thirty-two cases Griesinger had ten deaths; out of twenty-one Jenner lost seven; out of fourteen Gietl lost six; and Jaccoud had six deaths in six cases (*Pathologie Interne*, t. ii. p. 758). Bauer, however (*Schmidt's Jahrbücher*, Bd. clvi. p. 101), is in agreement with Liebermeister in believing that the baths should be discontinued during intestinal hemorrhage. Yet their views seem to be based upon preconceived theory rather than upon actual trial. Thus, Liebermeister says, "I have thus far ordered the baths entirely discontinued as soon as even slight hemorrhage from the bowels occurred." The proportion of cases in which intestinal hemorrhage occurs does not seem to be increased by the cold-water treatment; at least Golsdammer (*Berlin. Klin. Woch.*, 1877, p. 98) affirms that under the older methods thirteen thousand five hundred and sixty-three cases gave five hundred and thirty of intestinal hemorrhage, while five thousand six hundred and thirty-six cases of cold-water treatment yielded two hundred and forty of intestinal hemorrhage, the percentage being in the two cases respectively 3.9 and 4.2. Menstruation is not looked upon as a contra-indication. Brandt appears to consider a contra-indication to the use of the cold bath in typhus fever a myth, and the drift of testimony is such that no local internal disease ought in the present state of our knowledge to be considered as absolutely contra-indicating the use of cold baths when the temperature is high in typhus or typhoid fevers.

It is otherwise when there is a general tendency to collapse,—when the heart is so weak that local stases of blood occur in almost all the

internal organs. Under these circumstances the circulation has not sufficient power thoroughly to equalize animal heat, so that it is said to be entirely possible to cool the exterior of the body several degrees without materially affecting the temperature of the interior. One of the severe accidents which it is affirmed has very rarely followed the use of the cold bath in pyrexia is a sudden collapse; and clinical experience seems to indicate that when collapse is already existent the cold bath should not be administered.

In no disease attended with a long-continued pyrexia has the cold-water treatment been employed upon so grand a scale as in *typhus* and *typhoid fevers*; but the results there obtained are sufficient to indicate its usefulness in allied diseases. Of all the exanthemata, none is more constantly attended with excessive temperature than is *scarlet fever*. In this disorder the testimony to the value of cold is very strong. Going back to Currie, who really first systematized the abstraction of heat in fever, we find that he habitually practised in the most heroic manner cold affusions in the treatment of scarlet fever, and claimed the greatest success for the measure. Since his day the remedy has been employed with asserted good results by various observers, among whom may be mentioned Gérard, Bruère, Giannini, Armstrong, Laycock, Rilliet and Barthé, Trousseau, and Hiram Corson of Pennsylvania. The evidence is, unfortunately, too much generalized to allow of its being put in a statistical form, but for an extended résumé of it the reader is referred to the excellent article in Meigs and Pepper's work on the diseases of children. In almost all of these cases the cold was applied in the form of affusions, a method which is certainly far more terrifying to the child, and probably less efficient, than the cold bath. Recently, Dr. G. Mayer (*Jahrbuch für Kinderkrankheiten*, vii. 4) has been placing the child in a bath of from 93° F. to 73° F. (according to the intensity of the fever) for ten minutes, whenever the temperature rises above 102° F. He affirms that the effect was most beneficial, and that the reduction of temperature usually lasted for several hours. In *diphtheria*, cold bathing has been used to some extent, with seemingly good results. In both this affection and in *anginose scarlatina* it is of the utmost importance to combine the cold bathing with the local application of the ice-bag or ice-poultice to the throat. During the summer months *serous diarrhoea* (*cholera infantum*), in some of its forms, annually destroys large numbers of children in this country. In most of these cases the bodily temperature is, first or last, much elevated, and the diarrhoea is produced and maintained by the heat, as originally pointed out by Dr. Comegys (*Philada. Med. Times*, v. 665; *Amer. Journ. Med. Sci.*, Oct. 1876). All the ordinary methods of drug-administration frequently fail, or, at most, succeed only in keeping the child alive until the heat of the weather subsides. Under these circumstances antipyretic treatment acts in a magical manner. I have always found simple bathing in water of about 75°, at intervals of from three to six hours, sufficient,

but in some cases the plan recommended by Dr. Comegys may be required,—namely, by cold affusions while the child is sitting in a cold bath. The effect is usually immediate, quiet and sleep at once replacing the wakeful restlessness so distressing to mother and child. There may be a few instances of sudden collapse with low temperature from exhaustion by the serous discharges, but usually cases in which the disease is said to “go to the head” are those in which the temperature rises so high as to produce brain-symptoms: under these circumstances the vigorous use of external cold is imperatively demanded.

It is in the highest degree probable that systematic cold bathing will be found serviceable in all blood-poisonings with high temperature, such as smallpox, erysipelas, pyæmia, etc.; but as yet we have no clinical evidence of moment upon the matter. The high temperature that prevails in athenic pneumonia and certain other inflammatory diseases would appear to indicate the abstraction of heat; but how far the local disease will be advantageously or disadvantageously affected in these cases is as yet an open question. Dr. G. Mayer (*Schmidt's Jahrb.*, Bd. cxlix. p. 347) is stated to have found that desferescence is materially hastened, both in men and in children, by cold bathing. Dr. Kissler (*Virchow's Archiv*, Bd. xciv. p. 490) had in one epidemic a mortality of 17.4 per cent. in twenty-three cases treated with the cold bath, and of 57.1 per cent. in twenty-one cases treated otherwise; and Liebermeister states that whilst in six hundred and ninety-two cases of pneumonia treated in the hospital of Basel in various ways the mortality was 25.3 per cent., in two hundred and thirty cases treated in the same hospital by the thorough antipyretic method the mortality was only 16.5 per cent. Liebermeister has also employed the method in catarrhal pneumonia, puerperal fever, cerebro-spinal meningitis, acute rheumatism, erysipelas, smallpox, and quinsy, and affirms that he knows of no case with acute febrile symptoms in which, if the rise of the temperature were considerable, or lasted too long, he should consider heat-abstraction unsuitable treatment. In dysentery, Dr. B. Wenzel (*The Doctor*, 1874) strongly advises the use of large enemata of ice-water, which by their local action relieve very greatly the pain and tenesmus and at the same time have a decided effect upon the pyrexia.

In carrying out the antipyretic treatment of fever certain general considerations should never be forgotten. It appears to be impossible to give a fever patient cold unless the temperature of the body be reduced to near the norm. In many instances the fall of temperature continues after the patient has been taken out of the bath: hence the bath should not be too prolonged. I have been accustomed to believe that the good achieved by the bath was simply the result of withdrawal of the heating, and have therefore employed it only when the excessive bodily temperature threatened injury, and have considered the danger-point to be a mouth-temperature of 103° F. Some of the Germans, however, employ the bath whenever the temperature reaches

102° F. in the axilla. As it is possible to cool the axilla without cooling the interior of the body, all temperatures should be taken in the mouth or the rectum. Again, no bath or other application does good unless it removes the heat, but the cold should never be applied more severely than necessary. I have used cold spongings, cold packings, and the various baths, and have found that when a portable bath-tub can be brought to the bedside of the patient and readily filled and emptied, its use is accompanied with less fatigue and disturbance than any other efficient means of employing cold. The patient, wrapped in a sheet, is to be *lifted* by two attendants into the bath, and then made comfortable with pillows, etc. Unless the pyrexia is very severe, the bath should be at a temperature of 90° F. and cooled down *pro re nata*. When no portable bath-tub is at hand, sufficient antipyresis may be had by lifting the patient, wrapped in a sheet, upon a cot covered with a rubber blanket, and sousing rather than sponging him with cold water from a large carriage-sponge. If the sacking-bottom or the canvas of the cot be so loose as to sag down several inches, and the rubber blanket be turned up at the bottom and top over a wide board nailed across the top and bottom, the patient during the sponging lies in a big pool of water, and all the effect of the cold bath is obtained by removing with a carriage-sponge this water as fast as heated, and sousing fresh cold water (ice-water if necessary) freely over the upper part of the patient. Under no *circumstances* should the patient be *allowed to help himself at all* during the various movements. When the extremities seem especially affected by the bath, they should be rubbed so as to maintain their circulation. I have frequently applied hot-water bottles to the feet while the body was being bathed, with good effect.

CHAPTER IV.

ELECTRICITY.

GENERAL CONSIDERATIONS.—Electricity is a force which is developed in various ways, but which is essentially the same entity under all circumstances. When it is obtained by rubbing two

FIG. 1.

surfaces together, it is known as frictional electricity; when it is obtained by the union of two dissimilar metals, it is called galvanism. Frictional electricity is almost never used in medical practice, and I shall say nothing more about it in this book.

There are a large number of different patterns or arrangements of the elements which generate galvanism, but the ideal or typical cell may be said to be formed of two dissimilar metals immersed in some corrosive liquid and connected with each other by a piece of wire externally. Under these circumstances the current starts from the metal most easily corroded, passing through the liquid to that less easily acted upon, and from this over the external wire to the starting-point. The external end of the least-easily corroded plate is therefore always giving off electricity, and is known as the + or positive pole, while the corresponding end of the other plate is constantly receiving electricity, and is spoken of as the — or negative pole. When wires are attached to these plates they become, as it were, prolongations of the plates, and their ends constitute the poles. Thus, in the diagram, *C* = copper, *Z* = zinc, *P* and *N* = poles, and the arrows show the direction of the current. The positive pole is called the *anode* (*ἀνά*, upwards, and *ὁδός*, a way); the negative, the *cathode* (*κατά*, downwards, and *ὁδός*).

As the electric current does not primarily exist, it is evident that in the typical or ideal galvanic cell there must be something which sets it in motion. This force is the so-called electro-motor force, and has been determined by physicists to be a definite quantity for the same combination of metals at the one temperature. This force is generated at the point of contact of the metals, in obedience to the law discovered by Volta, that when two metals are in contact with each other a disturbance of the electrical conditions of those metals occurs. The amount and energy of this disturbance vary according to the nature of the metals, and experiments have shown that all metals have

definite electro-motor powers or properties, and that they can readily be arranged in a regular series. A study of this series is not necessary to an understanding of electro-therapeutics, and the reader desirous of knowledge upon this especial point is referred to works on physics. It must be borne in mind that the electro-motor force is constant, so that in any given combination of metals in a galvanic cell the electro-motor force is always the same, whether the plates of the metal be large or small, whether the solution be an acid, a saline, or pure water. The strength of the current is not, however, decided entirely by the electro-motor force of the cell. Every known substance refuses more or less imperiously to allow the passage of electricity. The best conductors oppose a really very great resistance. Now, it is evident that this resistance is opposed to the electro-motor force, and that if it be greater than the latter it will altogether prevent the passage of any current. The strength of the current, then, depends upon the relation between the resistance and the electro-motor force; and we have the celebrated law of Ohm, which may be expressed by the formula c (current-strength)

$$= \frac{e \text{ (electro-motor force)}}{r \text{ (resistance)}}.$$
 This law experiment has shown to be imperative, no increase or diminution of the size of the plates, no change in the character of the solution, affecting it.

The resistance to the current in a galvanic combination is a double one: inside of the cell the fluid between the plates opposes the passage of the electricity, and outside of the cell the conductor which completes the circuit also offers a resistance. The reason a battery almost ceases to yield a current when water is substituted for the acid usually employed is not a purely chemical one, but simply because water is an almost complete non-conductor, and offers triumphant resistance to the current, while the acid conducts and readily allows the current to pass. The entire resistance (r) is then made up of two factors: the internal resistance (ir), and the external resistance (er). The formula of Ohm

may therefore be read $c = \frac{e}{ir + er}$.

As already stated, when the plates of a cell are increased in size the electro-motor force is not increased, but as the surfaces of the plates are increased the diameter of the conductor—i.e., the transverse section of the fluids between the plates—is increased; and consequently, as the resistance in a conductor is inversely as the size of its cross-section, the strength of the current is increased. To make this a little clearer, sup-

pose ir in a certain cell equal 10, then $c = \frac{e}{10 + er}$: if now the plates of

the cell be doubled in size, $c = \frac{e}{\frac{10}{2} + er} = \frac{e}{5 + er}$. A similar result—i.e.,

lessening of the internal resistance—can be achieved by shortening the distance between the plates of the cell,—i.e., the length of the con-

ductor,—or by in any way making the intervening liquid a better conductor.

The change in strength of a current by the increase of the size of the plates of the cells can readily be expressed by the formula of Ohm. If the letters signify as before, and the internal resistance be diminished y times by increasing the size of the plate y times, instead of $c = \frac{e}{ir + er}$

c will be $\frac{e}{\frac{ir}{y} + er}$. If, instead of a single cell, a number of cells are arranged in such a way that the copper of one is connected with the zinc of the next, the electro-motor force of the combination is equal to the sum of the electro-motor forces of the cell: thus, if e = the electro-motor force of the single cell, and y = the number of cells, the electro-motor force of the battery will be ye . It is plain that the internal resistance of the battery is also increased y times, so that the formula of Ohm will stand $c = \frac{ye}{yir + er}$.

Of course, the strength of a current is greatly affected by the external resistance. In very many instances the external resistance is enormous. Suppose, then, this external resistance in a given case be 1000 times the internal resistance, the formula of Ohm will read,

$c = \frac{e}{ir + 1000 ir}$. It is evident that under these circumstances ir , the internal resistance, becomes very insignificant, and that very little is gained by increasing the size of the plates,—i.e., by diminishing the internal resistance; for if the plates were increased fivefold, the increase of the strength of the current would only be the difference between $\frac{e}{5 + 1000 ir}$ and $\frac{e}{ir + 1000 ir}$, a difference which is very

slight. On the other hand, when the external resistance is very great, everything is gained by increasing the number of cells,—i.e., increasing the electro-motor power; for $\frac{5e}{5ir + 1000 ir}$ gives a very different result from $\frac{e}{ir + 1000 ir}$. When, therefore, the external resistance is many times greater than the internal, practically nothing is gained by increasing the size of the plates, everything by increasing the number of the elements.

The converse of the above reasoning also holds. If the external resistance be very slight, the internal rises in importance. Thus, suppose $er = \frac{ir}{1000}$. Then the formula would be $c = \frac{e}{ir + \frac{ir}{1000}}$. In this

case a great deal is gained by increasing the size of the plates, for $\frac{e}{\frac{ir}{5} + \frac{ir}{1000}}$ gives a very different result from $\frac{e}{ir + \frac{ir}{1000}}$. In such a case,

by quintupling the size of the plates the strength of the current is practically increased fivefold. On the other hand, it is plain that when the external resistance is slight the gain by increasing the number of cells is a slight one, for the internal resistance is increased as many times as the electro-motor force. Thus, if five cells are used, the formula will be $c = \frac{5e}{5ir + \frac{ir}{1000}}$, which will, of course, give practically

the same result as $\frac{e}{ir + \frac{ir}{1000}}$.

The law, then, may be stated to be that when the external resistance is very slight, increasing the number of the elements has no practical effect upon the strength of the current, while an increase of the size of the elements has the greatest effect.

When there is no very great disproportion between the internal and the external resistance, it is evident that the strength of the current may be increased by increasing either the size or the number of the elements. Thus, if $er = ir$, $c = \frac{e}{ir + er} = \frac{e}{ir + ir}$; and increasing the size of the plates

fourfold will give the formula $c = \frac{e}{\frac{ir}{4} + ir}$; or increasing the num-

ber of the elements to four will yield the formula $c = \frac{4e}{4ir + ir}$. Per-

haps the result will be clearer if figures be used. Suppose $e = 100$, $ir = 10$, and $er = 10$. Then the first formula will be $c = \frac{100}{10 + 10} = 5$;

the second, $c = \frac{100}{\frac{10}{4} + 10} = 8$; the third, $c = \frac{400}{40 + 10} = 8$. When,

therefore, the external and the internal resistance are equally balanced, the strength of the current is equally increased by increasing either the number or the size of the plates.

The application of the foregoing principles to electro-therapeutics is a very simple one. In the ordinary applications of electricity to the body, the resistance of the tissues is very many times greater than the internal resistance of any battery, and consequently the latter may be totally disregarded. Hence for ordinary purposes the formula stands $c = \frac{e}{er}$, and power can be gained only by increasing e ,—that is, by augmenting the number of cells.

When, however, it is desired to act upon the blood in an aneurismal sac, the needles are brought close to each other; and, moreover, the blood is a comparatively good conductor of electricity. Hence in such cases the external resistance is so much reduced that the internal

becomes of such importance that it should not be overlooked. It follows, therefore, that when an aneurism is to be acted upon the plates should be increased in size, while at the same time a number of cells should be used.

In the so-called "galvano-cautery" the current is not passed through the body at all, but through a wire, which is thus kept at a white heat. In this case the external resistance is vastly less than when human tissues form a part of the circuit. Hence it becomes a matter of importance to reduce to as great a degree as possible the internal resistance, and the elements or plates should be very large and should be placed very close to one another in the cells. The external resistance is not, however, so slight that it can be entirely overlooked, and hence a number of cells are combined with one another, so as to give sufficient electro-motor force.

In writing or speaking about the use of electricity in medicine, it is a matter of great importance to avoid the use of the old terms *quantity* and *intensity*, which, to use the language of one of the most eminent of living writers on galvanism, "are remnants of an erroneous theory." The amount of mystification which has been produced by talk concerning the therapeutic effects of currents of large quantity with low intensity as contrasted with those of currents of high intensity and low quantity is equalled only by the amount of nonsense which has been written. Currents of galvanism have really only one attribute, —i.e., current-strength,—and that is in strict accordance with the law of Ohm.

If $c = \frac{e}{r}$ it is evident that, in order to have a unit by which there can be a measurement of an electric current, it is necessary to have a unit of resistance and a unit of electro-motor force. The unit which has been finally settled upon by electricians as the measure of electro-motor force is known as a *volt*. It is equivalent to 10^8 (10 raised to its eighth power) absolute French units of force.* The unit of resistance is termed an *ohm*, and equals 10^9 absolute French units. Substituting these units for their representative letters in the formula $c = \frac{e}{r}$, we get $c = \frac{1 \text{ volt}}{1 \text{ ohm}}$. In this way the unit of current-strength is obtained, and is known as an *ampère*. This unit is, however, entirely too large for practical purposes. It is therefore generally substituted by the so-called milliampère, which is the one-thousandth part of an ampère, or $\frac{1 \text{ volt}}{1000 \text{ ohms}}$. The term galvanometer has long been used in electricity as the name of an instrument

* All forces are convertible into one another, and hence it is possible to refer the unit which is employed in measuring electricity, heat, or other force to what is known as the absolute unit of force. The absolute unit of force is always mechanical, and has in the past varied in different countries. At present, however, scientists almost universally adopt the French unit, which is a representation of the amount of force required to raise one gramme through one centimetre of distance in one second.

which shows the existence of an electro-current. An absolute galvanometer is one which reveals not only the current, but also the amount of electricity that is passing. As good absolute galvanometers are now manufactured which measure the current in milliamperes, it would seem at first to be a very easy matter, in testing the excitability of nerves or in reporting cases treated by electricity, to state exactly how many milliamperes passed through the nerve or through the system; in other words, it would seem easy to have a dosage of electricity comparable to that of medicines. Unfortunately, the affair is not so simple,—chiefly on account of the diffusion of the electrical current which naturally takes place during its passage through the human body. If, for instance, an electrode of a square inch of surface be used, the effect upon the organism must be different from that which would be obtained by employing an electrode of twenty square inches. In the one case a concentrated current would pass at least for some little distance into the body, in the other a large number of proportionally feebler currents would enter from the beginning. More than this, when it is intended to galvanize a fixed spot, as a ganglion or nerve-trunk, it is rarely possible to note exactly what portion of the current which enters the body reaches the desired spot, and how much of it is diffused through other tissues. (See paragraph on conduction.) In order, therefore, to compare results obtained by different electricians, or by the same electrician upon the same case in successive days, or in different cases, it is essential to know exactly the size of the electrodes and the positions at which they were placed upon the body. To facilitate measurements, Mr. C. W. Müller has proposed that in therapeutic electricity a fraction be used to express the concentration of the current which is employed, the numerator of the fraction to consist of the number of milliamperes, the denominator of the number of square centimetres in the electrode. Thus, the fraction $\frac{1}{30}$ would mean that a current of one milliampere strength had been employed with an electrode of thirty centimetres of surface, while the fraction $\frac{4}{16}$ would mean that the current of four milliamperes had been employed through an electrode of sixteen square centimetres of surface. These fractions do not express in any way the relative positions of the electrode, and the alteration of half an inch in the position of an electrode on the surface of the body may double or halve the amount of a current which reaches the desired spot. Practical dosage of electricity in therapeutics is probably a chimera, and certainly has not yet been satisfactorily achieved. It is possible that in certain delicate cases, with very careful investigators, the measurement may be employed with advantage for the study of physiological results. But one who is familiar with the average training in physical science of physicians who use electricity must, I think, recognize that the publications of electrical measurements amount to little more than a show of scientific accuracy.

For ordinary use in diagnosis and treatment of disease galvanome-

ters are not required, the experienced medical electrician being sufficiently guided by the sensations of the patient and the muscular effects achieved.

A dense fog has been thrown around the subject of electro-therapeutics by the idea that there are various essentially different forms of galvanism. The current which flows from a cell or a combination of cells is spoken of as a *continuous current*, or sometimes as a *primary current*; besides this, modern therapists use another series of currents, which are known as the *induced currents*.

The term *primary current* is often applied to one of these induced currents. If we employ the name *continuous current* for that current derived from the galvanic cell, we must continually be speaking of the interrupted continuous current, which certainly is inelegant. I shall, therefore, employ the name *chemical current* or *galvanic current* to designate that form of galvanism which is generated in the galvanic cell.

If a coil of insulated wire have a bar of soft iron placed in its centre and be surrounded by an external coil of wire, when a chemical current is passed through the first coil, owing to physical laws which it is not necessary here to consider, every time the galvanic circuit is completed or interrupted a brief current of electricity is induced in the inner or first coil, and also a similar current in the outer or second coil. The only physical facts which it is necessary for us to know are that these induced currents are very brief and of great strength, also that they are to-and-fro currents,—that is, run in opposite directions in each individual coil. Thus, in the inner or first coil, when the galvanic circuit is closed, the induced current in the inner coil runs parallel to the generator chemical current; but when this latter current is broken, the induced current runs in a contrary direction. In the outer coil, the induced current, which is instantaneously developed when the galvanic current is sent through the inner coil, pursues a direction opposite to that of the chemical current; but when the latter is broken, the return induced current in the outer coil runs parallel to the generator current.

As these induced currents run backwards and forwards, to and fro, in this way, it would appear that there could not be any negative or positive pole to the battery which generates them, for if one end or pole of the wire constituting the coil be negative in regard to the first induced current, it must be positive in regard to the second or return current. This is assuredly true so far as concerns the outer or second coil, but is not true for the inner or first coil, as is readily understood by means of the diagram of an induction battery given on the opposite page.

It is plain that when the current is passing, the hammer *h* being in the position represented in the diagram, *m* will become magnetic and attract *h*. This at once breaks the current, and an induced current runs through the first coil and is received by the patient grasping the handles *P P*. The instant the current is interrupted, *m* loses its magnetism and the spring-hammer flies back. Now the circuit is closed,

and for the second time an induced current runs through the first coil *c*. It is evident, however, that this induced current of closure will not pass through the body of the person grasping the handles *P P*, but will pass along *h* through the cell to the other end of the coil, as a shorter route and one of vastly less resistance. It is plain that from the inner or first coil the induced current of broken circuit alone passes through the body of the patient.

FIG. 2.

G, galvanic element, with the + and — metals in it; *c*, coil in which the primary induced current, or current of the first coil, is generated; *A*, spring-hammer or vibrator; *m*, a piece of soft iron becoming a magnet when the current is passing; *2c*, outer coil in which the secondary induced current, or current of the second coil, is generated; *P*, handles of inner coil; *P'*, handles of outer coil.

In regard to the outer coil, it is evident that when the circuit is closed the momentary induced current must run through the body of him who grasps the handles *P* and *P'*, and that the return current which passes when the circuit is broken must take the same route.

It follows from the above considerations that the *current of the first coil runs through the patient only in one direction*, and electricians may correctly mark poles + and —, but that the *current of the second coil runs in both directions*, so that any designation of its handles as positive and negative is incorrect. The only justification for the marking of the secondary or outer current poles, as is often done, is found in the fact that the induced current of the broken circuit is stronger than that of the closed circuit. Hence it is that with very strong currents the two poles can sometimes be distinguished when grasped in the hand. The difference is, however, a slight one, and for all practical

purposes the induced current of the outer coil is a to-and-fro one, without any negative or positive poles.

If a strong continuous galvanic current be passed through a person, a shock is felt at the moment of making and breaking the circuit, but while the current is passing no sensation is perceived except at the points of entrance and exit. Or if the current be passed through the nerve of a muscle, that muscle violently contracts at the moment the circuit is made or broken, but while the current is flowing is quiescent. If a rapidly-interrupted faradic current be passed through a nerve, the muscle supplied by that nerve is thrown into a continuous spasm. The reason of this is obvious. The so-called faradic or induced current is, as has already been stated, a succession of instantaneous broken currents for the first coil, and as brief to-and-fro currents for the outer coil; so that the circuit is continually being closed and broken, and the muscle is continually excited to action. There is, therefore, a different result achieved in the application of the continuous and induced currents, not because there is any real difference in their nature, but because the mode of application is diverse.

Most medical electricians teach that the true galvanic current is very different from the faradic current, and many, like Duchenna, persist in asserting that the currents of the first coil are essentially different from those of the second. Galvanism is, however, galvanism; and its nature and attributes are probably always the same; the faradic currents are lacking in the chemical power of the continuous current because they pass so quickly that they have not time to exert a chemical influence. Gunpowder can be passed so quickly through the hottest flame as not to be ignited. The secondary induced current differs somewhat in its action from the primary simply because the latter is not a to-and-fro current, and we cannot readily convert an induced into a galvanic or chemical current, because we cannot readily tie together, as it were, the ends of the brief currents into one. I have no doubt that if we could get the interruptions at the rate of many thousand times a minute, we should find that the primary induced current would act as a continuous current.*

We can readily, by mechanical means and contrivances, interrupt the continuous current, or even rapidly reverse the poles so as to give a to-and-fro current like that of the outer coil. When this is done, it is impossible to distinguish between the action of the galvanic and that of the faradic current in producing muscular contractions. It is true

* It has been found that when a faradic machine, or its equivalent, the so-called magneto-galvanic machine, is so constructed that the interruptions are excessively rapid and the to-and-fro currents separate from one another, the infinitely rapid succession of instantaneous induced currents in one direction has all the obnoxious effects of a steady current; in other words, the interruptions are so brief that they are without influence. I am not aware of any trials with these machines upon living tissues, but do not doubt that their currents will be found to produce the same results as chemical currents.

that in certain diseased states of the muscle it has been asserted, and with apparent reason, that the action of the induced current is essentially different from that of the true galvanic current. But I believe further investigation will show that the seeming differences are really due to the difference in the lengths of time during which the currents are passing, and not to any inherent peculiarities of the various currents themselves.

It is of the utmost importance to determine by what route or routes galvanic currents pass through the body when the poles are applied to it, and, since the body as a galvanic conductor is governed by ordinary physical laws, some knowledge of these laws is a necessity to the electro-therapeutist.

If a current be passing along a homogeneous conductor, such as a wire of iron, of copper, or of other metal, and that conductor splits up into a number of branches, the current also divides, as is illustrated in the diagram (Fig. 3). If these branches, being of equal size and length, offer an equal resistance, the current divides equally; but if the size or length, and consequently the resistance, of the branches be unequal, the division of the current is unequal; the law being that the strength of the current in each branch of the conductor is inversely proportional to the resistance of that branch. This law is as applicable to conductors composed of many substances as to those composed of a single substance; but then the resistance in a branch depends upon the specific resistance of the substance of which it is composed, as well as upon its size and length.

FIG. 3.

In applying these laws to the passage of galvanism through the body, it must be borne in mind that the dry skin offers an enormous resistance to the passage of the current, so that practically none of the latter will pass *along* it. On the other hand, when the skin is thoroughly wet with salt water it allows the current to pass *through* it readily.

Let us suppose, then, that in the diagram (Fig. 4) $+p$ and $-p$ = wetted poles; ss = skin, with the tissues below it. It is evident that, if the tissues were a uniform mass, the current, passing through the skin as a solid bolt, would break up into an infinite number of curved currents, which would meet and pass through the skin again as a solid mass at $-p$. It is equally plain that, of these sub-currents, those whose course was nearest the straight line from $+p$ to $-p$ would be the shortest, and would, therefore, meeting with the least resistance, be the strongest, while as the curve and consequently the length and the resistance increased, the strength of the current would diminish until it became practically null. In this imaginary case the tissue

beneath the skin has been supposed to be homogeneous: in actual life the tissue never is homogeneous, and the resistance of the different constituents varies somewhat. Consequently, the strength of the subdivisions of the current is modified,—those branch streams being increased which run along or through tissues that conduct readily, and *vice versa*.

FIG. 4.

By remembering these facts, we are enabled to apply electricity as closely as may be to any desired portions of the body. Thus, if it be intended to affect as exclusively as possible a certain spot or minute portion of a nerve, a well-wetted small electrode is placed directly over this portion, and, especially if the nerve be somewhat deeply situated, pressed down firmly, so as to condense the tissues as far as possible into a homogeneous mass, while a large wet electrode is placed at a small distance from it in a situation which the anatomy of the part will readily suggest. The diagram (Fig. 5) will perhaps illustrate this point more clearly than would many words.

FIG. 5.

It is evident that the spot immediately under the small electrode will receive the full strength of the current, which is directly afterwards so broken up as to affect very slightly any other part.

Again, suppose it is desired to pass a current through some length of a nerve; it is evident, in the first place, that two small electrodes should be chosen, and that they should be well wetted and pressed firmly upon the trunk of the nerve at the two ends of that portion which is to be affected. Again, in applying electric currents to muscles it is found that if the currents be sent through the body of the muscles, only very imperfect and partial contractions occur, unless indeed the currents be excessively strong. Duchenne was the first to discover

that when one pole is placed over certain spots or points in the muscle, violent general spasms of the muscle are produced by currents usually too feeble to elicit a distinct response. To these places the name of *motor points* has been given. These motor points correspond to the position at which the supplying nerve enters the muscle. When it is desirable to affect chiefly or solely a given motor point, it is evident that one small well-wetted electrode should be pressed firmly over the motor point, and another large sponge electrode placed at some little distance from it, in the manner which has already been explained.

For certain purposes, to be hereafter explained, it is often desirable to affect chiefly the skin by the electric current. Under these circumstances the skin should be well dried. It then offers so great a resistance that only currents of considerable strength are able to force their way through, and even these currents, taking advantage of the natural apertures formed by the sweat- and other glands, are broken up into a number of branch currents. The galvanic current reaches the internal structures in a great number of small streams very much reduced in power by the resistance they have overcome. If the second pole of the battery be a large well-wetted disk or sponge at a distant part of the body, it is evident that these branch currents will separate and subdivide in such a way that their effect upon the deeper structures will be almost entirely lost.

It is a principle in physics that electricity upon points does not strictly obey Ohm's law, but the force accumulates on the extreme end of the point until its density is excessive, and its self-repulsive power becomes so great as to overcome all resistance, and to break off highly electrified particles of the conductor, which fly off through the air. It is this that renders the so-called "electric brush" so energetic in its action on the skin. This instrument consists of a number of wires united in the form of a cylindrical brush and connected with one pole of the battery; when this is brought in contact with the skin of a person, on whom at some distance is placed the other large well-wetted electrode, each wire point offers a dense accumulation of electricity, which forces its way at all hazards through a minute portion of the skin. The whole current of course enters the deeper tissue in an infinite number of subdivisions, and consequently its effect in these tissues is reduced to a minimum.

PHYSIOLOGICAL ACTION.—When a moderately strong current of galvanism is passed along a certain length or portion of a nerve, there appear between the two poles two zones of disturbed nerve-function, separated by a neutral point at which the nerve retains its normal condition. In the neighborhood of the positive pole the irritability of the nerve, and also its power of transmitting impulses, are diminished, while in the proximity of the negative pole these nerve-attributes are increased: to the condition of diminished activity the name of *an-electronus* has been applied, while that of increased activity has been

called *katelectronus*. Thus, in Fig. 6, *cn* equals the nerve; $+p$ and $-p$, the positive and negative poles respectively; *np*, the point at which the function of the nerve remains normal, with the zone of anelectronus (*a*) on the one side, and that of katelectronus (*k*) on the other. The longer the current continues, and the more intense it is, the more does the zone of anelectronus gain upon that of katelectronus, or, in other words, the more closely does the neutral point (*np*) approach the negative pole ($-p$). Consequently, when a strong current has passed for a length of time through a nerve, the zone of katelectronus is a very short one, confined to the immediate vicinity of the negative pole.

When the particles of a motor nerve pass from a state of inertia to one of motility,—i.e., from one of diminished to one of increased excitability,—the nerve is momentarily excited, and gives origin to an impulse. Therefore, when anelectronus disappears in a nerve,—i.e., when a condition of diminished activity becomes one of normal activity,—an impulse is generated just as certainly as when katelectronus—i.e., increased functional activity—appears in a nerve previously normal.

Suppose (Fig. 6) *cn* represents a nerve, and *m* the muscle to which it is distributed. If, then, a downward current be applied to this nerve,

FIG. 6.

it is plain, $+p$ being the positive pole and $-p$ the negative, that *a* will be the zone of anelectronus, *np* the neutral point, and *k* the zone of katelectronus. When the circuit is closed in obedience to the law already enunciated, an impulse starts from *k*, and, in order to reach *m*, has to pass only through the stretch of normal nerve between $-p$ and *m*. Therefore this impulse of circuit-closure reaches the muscle unimpaired.

Again, when the circuit is broken, the impulse which is generated in *a*, in order to reach the muscle travels only through the zone *k*, whose conducting-power is increased, and a portion of normal nerve; consequently it also reaches the muscle unimpaired. It is plain, then, that with descending currents strong movements must be induced, both at the making and at the breaking of the circuit.

With ascending currents the results are different. Thus, in Fig. 7, *cn* = nerve; *m* = muscle; $+p$ = positive pole; $-p$ = negative pole;

FIG. 7.

np = neutral point; *a* = zone of anelectronus; *k* = zone of katelectronus. Now, it is plain that the impulse generated in *k* at the closing

of the circuit must pass through *a*, the zone of diminished conducting-power, in order to reach *m*. Consequently, with the ascending current the contractions of circuit-closure are very feeble, or are altogether wanting. When, however, the circuit is broken, the impulse generated in *a* reaches the muscle *m* unimpaired.

Without occupying more space with a discussion of the subject of electrotonus, but contenting myself with the statement that these facts and reasonings apply especially to such currents of moderate strength as are with propriety employed in therapeutics, it is plain that descending currents ought to be more efficient in inducing contractions than are ascending currents. What science thus has discovered, clinical medicine has also found out: descending currents are in practice found to be more powerful than ascending currents.

From what has been already said, it is so evident as scarcely to need further demonstration that the breaking of a current running in one direction must render the nerve more sensitive to the closure of a current running in the opposite direction, but less sensitive to the closure of a current running in the same direction; for when the currents pass in opposite directions anelectronus suddenly becomes katelectronus, —i.e., that which was below normal suddenly becomes above normal, —while with parallel currents anelectronus remains anelectronus.

To make this more clear, however, Fig. 8 may be employed. In it the letters have the same significance as in those previously used, while the arrows on the side of the lettering represent the direction of the current to which the lettering applies. The downward current is supposed to be broken, and to be followed instantly by the upward: of course the upper, *a*, changes into *k*, and a doubly powerful impulse is sent down to *m*. Now the upward current is broken, and the downward sent through the nerve; at once the lower *a* becomes *k*, and *m* receives again a doubly powerful impulse.

FIG. 8.

The practical application of this reasoning is a very apt one. It becomes, in the first place, very plain why the secondary to-and-fro current of the induction coil has so much more power over muscles than has the primary induced current or the chemical current, as ordinarily applied.

If, however, instead of the chemical current being simply interrupted, its polarity be suddenly reversed at brief intervals, all the effects of the to-and-fro induction current upon healthy muscle are obtained. More than this, for reasons to be hereafter adduced, in cer-

tain muscular paralyses I have found that muscles which fail to respond to all other currents respond readily to a very slow to-and-fro chemical current.

Having obtained an idea of the manner in which galvanic currents produce muscular contraction, it is next in order to study their influence upon diseased muscles.

If a muscle by destruction of its supplying nerve be cut off from all spinal influence, it or its nerve rapidly undergoes a degeneration.* In the course of a very few days it will be found upon testing that the muscle no longer responds to a rapidly-interrupted faradic current, but does respond to such current when slowly interrupted; a couple of days later, and the muscle fails to contract to the most powerful and most slowly-interrupted induced currents. When, however, the continued current is applied, and is very slowly interrupted, or, better still, reversed at intervals of one or two seconds, contractions are produced. It is this fact that has led to the belief that there is some intrinsic and inscrutable difference between the induced current and the chemical current. But time is an element required for the propagation of any force. If the hand be passed rapidly through a flame, the latter is not felt; if the hand move more slowly, a sensation of warmth is perceived; if the motion be still slower, this sensation becomes pain. Now, if the hand be partially anæsthetic from disease, in order for the sensation of warmth to be perceived motion must be much slower than in the first instance. In other words, more time is required for the partially paralyzed sensory nerve to perceive heat than for the normal nerve to do so. What is true of the sensory nerve is true also of the motor nerve. It does not respond so quickly to stimuli when partially paralyzed as when normal. The muscle first loses its power of responding to those faradic currents which are excessively rapid, then to those which are less so, and finally to all induced currents, because from their very nature these currents, even when slowest, last but a fraction of a second. The chemical current may be continued for any length of time at the will of the operator, who is thus enabled to act upon a muscle whose nerve has become so insensitive that it fails to perceive the flash of faradic galvanism.

The proof of this somewhat dogmatic reasoning is to be found in the fact that the rapidly-interrupted chemical current is no more able to affect the diseased muscle than is the rapidly-interrupted faradic current, as I have proved over and over again in various forms of paralysis. That there is no difference between the chemical and the induced currents in their chemical action, except in so far as their influence is affected by the duration of their passage and the to-and-fro character of many induced currents, is abundantly proved by the "Gramme magneto-electric machines," in which an induced current is

* The peculiar electrical reactions of a degenerating muscle are given in detail on p. 88.

obtained with almost infinitely rapid interruptions and running only in one direction. With this current all the phenomena of chemical decomposition, etc., are obtained, and no doubt the effects of the continued chemical current upon the human frame would be producible.

THERAPEUTIC APPLICATION.—Most of the therapeutic applications of electricity are considered in this book under special headings, but it seems proper at this place to call attention to the use of the current for the relief of various local *rheumatic* affections. In subacute or chronic muscular rheumatism faradization is often of great service, and even in rheumatic diseases of the joints it sometimes brings marked relief. When the symptoms are acutely inflammatory they must first be subdued by suitable measures; but when they are subacute the current may be employed at the beginning of the attack. It should be rapidly interrupted, and should be as strong as can be borne by the patient. The first séance should last but five minutes, but the time of application can be gradually protracted to fifteen or twenty minutes.

Motor System.—Galvanic currents are employed in paralytic affections for three distinct purposes,—namely, *diagnosis*, *prognosis*, and *therapeusis*. These I shall consider in the order in which they have been named.

There are certain palsies, such as pseudo-muscular hypertrophy, in which the muscular structure is so destroyed independently of any involvement of the nervous system that no response to the galvanic current is possible. All of these palsies are, however, essentially exceedingly chronic, and their diagnosis is to be made out chiefly by a microscopical examination of the muscles themselves. As electricity does not come into play in the diagnosis of these cases, I shall not say more about them. It is otherwise with suddenly-developed paralysis in which the history does not point to any immediate cause, such as diphtheria. Often, in such cases, galvanism is of great diagnostic value. As stated previously, when a muscle is entirely deprived of the influence of the spinal centres it rapidly loses its electro-contraction, whereas, if a muscle be paralyzed from a lesion of such character or position as not to interfere between it and the trophic cells of the cord, it maintains its integrity for many weeks. When a muscle is degenerating for want of spinal influence, it first loses its power of responding to rapidly-interrupted faradic or chemical currents, then to slowly-interrupted faradic currents, then to slowly-interrupted chemical currents, and lastly to slowly-reversed chemical currents. At this time occurs with the galvanic current the so-called "*reaction of degeneration*," first discovered by Brenner, and since elaborated by Erb (*Ziemssen's Encyc.*, xi. 273) and G. B. Massey (*Med. News*, Feb. 1883, p. 124). To comprehend this, it must be remembered that it is obtainable only by applying the electrode to the muscle: if the electrode be applied to a nerve-trunk of a degenerating muscle it will be found that reaction is diminished in quantity but not altered in quality. When a

galvanic current of only moderate strength is used, and the negative pole (cathode) placed over the normal muscle but not over its motor point, a strong contraction occurs at the closure of the circuit; when, however, the positive pole (anode) is placed over the normal muscle, the contraction is much less; in neither case is there any contraction when the circuit is broken; in other words, with the normal muscle and a feeble current we obtain good cathodal closing contraction, slight anodal closing contraction, and no motion whatever at either cathodal opening or anodal opening. When a current of sufficient power is used, opening contractions are produced, and the anodal contraction is greater than the cathodal. The "reaction of degeneration" consists merely in a more or less perfect reversal of the above formula. The anodal (positive pole) closure then causes a stronger contraction than the cathodal (negative pole) closure. When there is only a slight degree of degeneration present, there is a correspondingly slight increase of anodal closing over cathodal closing contraction. A minimum degeneration would be indicated by an equality of the two closing contractions.

These alterations in the electrical relations of a degenerating muscle are readily formulated, and in this way are perhaps more readily grasped by the student. The symbols are as follows: An Cl C represents *anodal closing contraction*; An O O represents *anodal opening contraction*; Ca Cl C represents *cathodal closing contraction*; Ca O C represents *cathodal opening contraction*; < represents *is less than*; > represents *is more than* (the point of the < being towards the lesser quantity). Then the formulas are:

$$\begin{array}{lcl}
 \text{An Cl C} < \text{Ca Cl C} & \} & \text{muscle normal.} \\
 \text{An O C} > \text{Ca O C} & \} & \\
 \text{An Cl C} = \text{Ca Cl C} & \} & \text{muscle in first stage of degeneration.} \\
 \text{An O C} = \text{Ca O C} & \} & \\
 \text{An Cl C} > \text{Ca Cl C} & \} & \text{muscle in a more advanced stage of degeneration.} \\
 \text{An O C} < \text{Ca O C} & \} &
 \end{array}$$

After the latter Reactions of Degeneration (De R of some authors) have been established, if the muscle continues to undergo change, the galvanic irritability slowly diminishes, stronger and stronger currents being required to produce an effect. When a certain stage is reached, all reactions cease, save a feeble An Cl C, and at last this is lost and the muscle responds not at all. When recovery occurs, the electrical reactions of the muscle pass upwards along the pathway they have descended.

The practical importance of the Reaction of Degeneration is greatly lessened by the circumstance that its demonstration usually requires much skill and patience,* and that it probably is never present when a

* Dr. Massey gives the following directions as to the method of making the test: "Having placed one well-moistened electrode over the muscle to be tested, and the other in

muscle still retains its integrity as regards the faradic current. For the purposes of the practitioner, the failure of response to the latter current is the best test as to the condition of a muscle. When a muscle loses its power of responding to the rapidly-interrupted faradic current in a week or ten days after the occurrence of paralysis, whether the reaction of degeneration can or cannot be satisfactorily demonstrated, the inference is very positive that the lesion either is one of the nerve-trunk, or, if of a nerve-centre, is of such a character as seriously to involve the trophic coils of the spinal cord. If a few days later such muscle is unable to respond to any faradic current, this inference becomes a certainty. Under these circumstances, the possible lesion is narrowed down to infantile paralysis, a conceivable destructive myelitis, and an affection of a nerve-trunk.

A *myelitis* so rapid and severe as to destroy in a few days a portion of the spinal cord, and consequently the electro-contractility of its tributary muscles, is exceedingly rare, and, if it occurred, could only be confounded with spinal congestion complicated with hemorrhage. In *infantile palsy* the nature of the case is usually but too apparent, although the muscles often lose their electro-contractility as quickly as when a nerve-trunk is severed. Practically, therefore, very rarely is there any difficulty in recognizing the seat of the lesion in acute or organic palsies by means of the galvanic test. It may be laid down as a practical rule that *when in the adult a muscle loses to a sensible degree in a few days its electro-contractility, the lesion is in a nerve-trunk*. In recognizing, however, these peripheral palsies, it must not be forgotten that the injury to the nerve may be very deeply situated,—even within the membranes or substance of the nerve-centres. This is especially to be borne in mind when it is a cerebral nerve that is affected. Thus, a tumor situated in a superficial portion of the brain may press upon the fibres of a nerve just as they are collecting together previous to leaving the brain, and the result will be a palsy which is really a peripheral one, although the tumor is in the nerve-centre. A similar thing may happen to the spinal cord: thus, I have seen, in spinal congestion giving origin to meningeal apoplexy, *rapid* and total destruction of the electro-muscular contractility in the lower extremities, from the pressure of the clots upon the cauda equina.

The persistence of the muscular contractility intact for some weeks after the occurrence of a palsy depending upon an organic lesion proves

some carefully-selected point of departure, it next becomes necessary to close and open the circuit properly. For this purpose nothing is in any way comparable to a pedal rheotome, a simple mechanism worked by the foot; it is, in fact, a necessity whenever the services of an assistant cannot be obtained, as a steady application of the electrodes is essential in many delicate cases,—even the slightest movement produced by the working of the hand-current-breaker being confusing. If the pedal rheotome also contain a commutator, worked by the foot, for changing the poles while still *in situ*, its handiness will be greatly increased. The clock-work current-breakers usually furnished by instrument-makers are totally unfit for diagnostic purposes."

that the disease is of cerebral origin, or, being spinal, is of such nature as not to compromise seriously the trophic nerves of the cord.

In applying these rules, it must not be forgotten that whenever a muscle is not used it loses its contractile power, so that even in paralysis from cerebral hemorrhages the muscles finally degenerate, although this degeneration is rarely so complete as in peripheral palsies. It is not the fact of degeneration, but its degree, and especially the period of time which elapses between its occurrence and the commencement of the paralysis, that is the important factor in the diagnosis. In cerebral palsies no distinct loss of functional activity in the muscles is usually perceived sooner than six weeks after the onset of the attack; and even after years have elapsed some response may often be elicited by strong slowly-interrupted or reversed currents.

There are certain palsies in which the electro-muscular contractility is really or apparently above normal. Very frequently the excessive contractions produced are not so marked in the muscles to which the currents are applied as in other muscles, whose movements are in reality reflex in their nature. In all these cases the probabilities are that there is a condition of acute hyperæmia or of excessive functional irritability of the spinal cord.

In regard to certain so-called functional palsies: in *diphtheritic paralysis* the irritability of the muscles is often diminished and sometimes destroyed; in *lead palsy* it is generally lost, and, curiously enough, according to my own observation the muscles may recover to a marked degree the power of voluntary motion, without a corresponding restoration of their normal electrical relations.

In *hysterical paralysis* any aid to diagnosis is often of very great value; and it has been asserted that in this class of palsies the preservation of electro-contractility with loss of electro-sensibility is always present, and is of diagnostic import. My experience, nevertheless, is very positive that in hysterical palsy both electro-contractility and electro-sensibility are frequently normal. When, however, the paralyzed muscle responds to galvanic currents, and the patient is to a great extent, or altogether, insensible to their passage, a very positive diagnosis of hysteria may be given. The electro-contractility is never seriously compromised in hysterical palsy.

In using galvanism as an aid in *prognosis*, the condition of the muscular contractility is always to be considered in conjunction with the nature of the lesion and the length of time it has existed.

Taking first ordinary *hemiplegia* as the type of *cerebral palsies*, it must be borne in mind that the actual existent amount of paralysis is really the product of two essentially different factors. The nerve-centre is primarily damaged, and after a time the muscle also suffers loss of structural integrity from want of use. The restoration of the nerve-centre does not necessarily involve the restoration of the muscle, so that in a case of hemiplegia of some standing the cerebrum may

have recovered itself partially or entirely, and yet the muscle be in such a state of degeneration as to be unable to respond to the impulse transmitted to it from the nerve-centre.

Under these circumstances, galvanic treatment, although unable to affect the nerve-centres to any extent, does great good by restoring the muscular tone. It is manifestly impossible in such a case to determine before treatment how far the nerve-centre has recovered itself, or, in other words, to what extent the existing paralysis is of centric and to what extent of muscular origin. When, in a case of apoplectic hemiplegia, there is no recovery at all of the power of voluntary movement after the lapse of six weeks, the prospect of decided improvement from electrical treatment is very gloomy, because the probabilities are altogether in favor of the existence of a serious, persistent centric lesion. If, however, there is some motion, the probabilities of improvement are inversely proportionate to the structural health of the muscles: *i.e.*, the worse the state of the muscle the better the expectation of relief. If the tone and the electro-contractility of the muscles are normal, the centric factor is the chief one in the production of the paralysis, and little good is to be achieved by the use of the galvanic current. On the other hand, if the muscles have undergone a very decided degeneration, much good is to be expected. No hopes of absolute cure should, however, be held out, because, in the great majority of cases, after the muscles have been fully restored the nerve-centre is found to be more or less damaged. The improvement under the use of electricity is usually at first rapid, but after a time ceases altogether, because, the muscles having recovered their tone, it is not possible to affect to any great extent the sole remaining cause of the paralysis,—*i.e.*, the centric lesion. Under these circumstances it is useless to continue treatment.

In *infantile paralysis*, early in the attack the galvanic current is of little value in determining the prognosis, except that the general law is, that the more rapidly electro-contractility is lost, the more serious is the case. In advanced cases, the duration of the attack and the condition of the electro-contractility in the muscles are both to be considered. If no response at all to an electric current can be obtained, the prognosis is always very grave; although even under such circumstances a decided improvement has occurred in a small percentage of the cases I have treated. If the case be an old one, the preservation of some degree of electro-contractility indicates that the structural lesion in the cord is not a fatal one; and as, under these circumstances, the muscles can always be more or less perfectly restored, the prospect of improvement is very good. The preservation of electro-contractility late in the disorder, when the centric lesion is no longer progressing, is of much more import than it is in the first few weeks or months of the case, when the central trouble may be increasing.

In *peripheral palsies* the prognosis depends rather upon the nature of the nerve-lesion than upon the condition of the muscle; but it must

be remembered that when a muscle has absolutely lost its power of responding to any electrical current its restoration is always a matter of difficulty and of some doubt.

In regard to *therapeusis*, the first point to be determined in acute cases is, very often, when to commence electrical treatment. When the lesion is of such nature as not to provoke any irritation of the nerve-centre, no time should be lost. Thus, if a man is unable to use his arm because he has slept with it under his head and thereby paralyzed the nerve by pressure, galvanism should be at once employed.

When, however, the lesion is of such character as of necessity to irritate the nerve-centres, the case is different. The local stimulation of the peripheral nerve-fibres by the electrical current does, in some way not yet definitely understood, affect the nutrition of the nerve-centres; and when these nerve-centres are in a state of active excitement or inflammation, a peripheral galvanic irritation may do serious injury. Hence the rule that when an acute palsy is connected with active irritation of the nerve-centres, galvanism should not be used upon the muscles until the centric disturbance has subsided. Thus, in *hemiplegia* from cerebral hemorrhage the muscles must be allowed to rest not only until all symptoms of centric irritation have passed away, but also until the brain has become so accustomed to the clot that the latter no longer acts as a foreign body. It is usually from three to six weeks before electricity can be used with advantage in these cases. Again, in acute *cerebritis*, *cerebral* or *spinal meningitis*, and *myelitis*, the employment of galvanic currents should be strictly forbidden until a stage is reached when the effects of the inflammation, and not the inflammation itself, are to be dealt with.

When it has been decided to commence the use of galvanism, it is next to be determined what current shall be employed. It has already been shown that there are no inherent mysterious differences in the various currents; yet there is a practical difference, and the clinical rule of choice is, *Always select that current which produces the greatest number of muscular contractions with the least amount of pain*; trying the rapidly-interrupted faradic or the rapidly-interrupted chemical current and the slowly-interrupted faradic or the slowly-interrupted chemical current, and always, when these fail to elicit response, the slowly-reversed chemical current, which, if necessary, may be increased in strength until the patient can no longer bear the pain.

The current having been selected, the *individual muscles* must be galvanized at each séance.

After what has been said previously, it is not necessary to speak at this point as to the best methods of applying the currents to the muscles, but only to insist upon the fact that it is not so much the electricity as the contractions induced by it that benefit the palsied parts, and that consequently the electro-motor points of the muscles should always be separately reached. The diagrams given in the Ap

pendix will point out more clearly than would pages of description the approximate positions of the motor points, which vary somewhat in their location in various individuals. Some deep-seated muscles we are not able to reach directly, but we can reach them indirectly by galvanizing the nerves which supply them.

There are certain precautionary rules which must never be lost sight of in the galvanic treatment of palsies. Pain is an evil, and its infliction is always to be avoided as far as possible. Hence the rule never to use stronger currents than is necessary. It is very possible to fatigue a healthy muscle, much more a diseased one. A weak muscle may be greatly injured by being over-fatigued. Hence the rule that currents are not to be applied to muscles sufficiently long at a time to induce fatigue. In general, an electrical séance should last from ten to twenty minutes, no one muscle being subjected to the currents for more than five minutes, and it may be repeated daily, or three times a week.

Sensory System.—Affections of the sensory nerves are of three kinds, —pain, hyperæsthesia, and anæsthesia. There are, of course, distinct states or disorders, which may exist separately or conjointly: as an instance of the coexistence of pain and anæsthesia may be mentioned the anæsthesia dolorosa of Romberg. The use of electricity for the relief of these disorders is almost entirely empirical,—indeed, is often purely experimental in an individual case, as no clinical laws regulating the use or enabling us to decide as to the applicability of the agency have as yet been worked out.

It may be laid down, however, as an axiom, that the galvanic current is powerless to relieve the pain of phlegmonous inflammations, and that its use should be restricted chiefly to nervous pain or neuralgia. It is also true that the currents are possessed of no therapeutic power over neuralgia dependent upon central organic lesions; this is also probably true of such neuralgias as *migraine*, *malarial hemicrania*, and *toxic neuralgias*, in which, although there is no perceptible organic lesion, there is some deep-seated, inherent deficiency either in the central nervous system or in the constitution or condition of the patient.

In *rheumatic neuralgias*, such as *sciatica*, electricity sometimes does great good, but perhaps more often fails. I have seen it effect the greatest good, and I have seen it aggravate the disorder. My experience has not been sufficient to allow me to speak authoritatively, but it appears to indicate that the currents are most successful when the stage of acute inflammation is past and when the pain is maintained by some persistent condition or habit of the nerve-trunk. In regard to the selection of the current, my experience is that it must be purely empirical. The most usually successful is a very mild (four to eight cells) chemical current, which should be passed steadily for ten minutes down the nerves. It should not be so strong as to give actual pain, and must not be interrupted. As in the great majority of cases this method of application yields the best results, it should always be tried

first. When it does good, it *nearly always* affords relief after, at the most, two or three sittings. Some cases receive most benefit from a rapidly-interrupted faradic current, which should therefore be tried if the continuous current fails. To the employment of electricity should of course always be added the proper constitutional treatment of the case.

In *hysteria*, in some cases whose nature is very obscure, and rarely as a sequela or result of a serious cerebral or spinal lesion which may have been more or less completely recovered from, there exist *local anesthesias* of the skin. When these are not dependent upon a too serious organic lesion, they are often very much benefited, or even cured, by the use of the electric brush. This should be large and composed of fine wires, while the other electrode should consist of a large, well-wetted sponge, placed upon a distant part of the body. Either the faradic or the chemical current may be employed; in either case it should be a very strong one.

APPLICATION TO THE NERVE-CENTRES, AND USE AS A TONIC.—Galvanism in various forms has been applied locally to the nerve-centres in various diseases. In regard to the brain, I have never yet met with any clear clinical evidence of good having been accomplished; and, with our present physiological knowledge, it is difficult to imagine in what way or under what circumstances cerebral galvanization can produce good results. On the other hand, harm certainly has been wrought by the application of strong currents to the head. Galvanic currents passed through the brain can act only as irritants, and I agree entirely with the dictum of Cyon (*Principes d'Electrothérapie*, Paris, 1873), that galvanization of the head ought to be abandoned.

An enormous amount of influence in all sorts of diseases has been claimed for the so-called *galvanization of the sympathetic*. In this application an olive-shaped electrode is pressed firmly into the auriculo-maxillary fossa, while a large sponge electrode is placed over or by the side of the sixth and seventh cervical vertebræ. For anatomical reasons, I do not believe it possible by this method to affect the upper cervical sympathetic ganglion; and the physiological and clinical evidence seems to me to point to the same conclusion. The ganglion is placed deeply beneath the carotid artery, and so situated that any current traversing it *en route* to the other pole, as usually applied, would have to pass through the vertebræ. The laws of electrical conduction, however, show that the currents would seek the routes of least resistance, so that it is *a priori* improbable that any appreciable portion of the galvanism would pass through the ganglion.

Leaving all this aside, the physiological proof that the currents of appreciable power do not reach the ganglion are, to my mind, absolute. When the slightest galvanic stimulus is applied to the bared ganglion, the results which follow are uniform, constant, and so apparent that a child can see them: they are dilatation of the pupil, and

contraction of the vessels of the eye, ear, etc., and *nothing more*. These results do *not* follow the application of the currents in man, as above described. It has been asserted that the vessels of the retina have been seen to contract; but Professor William F. Norris, one of the best ophthalmologists in the country, has very closely observed the retinal vessels under these circumstances, and has never been able to detect the slightest change. Moreover, some of the observers who have seen the vessels alter state that they dilate, while others affirm that they contract, or that they sometimes contract and sometimes dilate. If the vessels change under the influence of the current, why does not the pupil? Any unprejudiced observer can be convinced at once that it does not alter, and any prejudiced and not very skilful ophthalmologist may find in the retinal vessels what he expects. Drs. Beard and Rockwell strongly insist upon the possibility of galvanizing the cervical sympathetic, yet they acknowledge (*loc. cit.*, p. 129) "that the ordinary therapeutical measures for electrizing the sympathetics *do not* produce the same effects as electrizing the ganglia." This being so, it would seem unnecessary to discuss the subject further; yet I shall analyze somewhat the evidence upon which the gentlemen mentioned, along with other electro-therapeutists, rest an opinion so seemingly opposed to all scientific induction. This evidence, as founded on the large series of experiments of Drs. Beard and Rockwell, is embraced in the following paragraphs:

First. The alleged action on the retinal vessels.

Second. A hypnotic effect was sometimes perceptible, but *only* in the very nervous and impressionable.

Third. A sensible perspiration was caused when very strong currents were used.

Fourth. The pulse was sometimes accelerated, sometimes slackened.

In regard to the evidence contained in the first paragraph: as already stated, the results of observations are altogether contradictory, even Beard and Rockwell stating that "much seemed to depend on the temperament and condition of the individual; what would cause contraction in one would cause dilatation in another." The changes in the retinal vessels could not, under these circumstances, have been due to an action of the galvanism upon a ganglion, stimulation of which *always* produces contraction of the vessels: evidently, if alterations of the vessels really occurred, they were the results of physical or other influences, and not directly due to the galvanic current.

As none of the phenomena mentioned in the second, third, and fourth propositions are produced when the bared ganglia is galvanized, and as all of them are producible by pain or nervous excitement, it seems very plain that, like the asserted retinal changes, they must have had their origin in the psychical disturbance of observer or patient.

Very great therapeutic value has been attached by various writers to the effect of *galvanization of the spinal cord*. As in the case of

the sympathetic, most opposite opinions are held by equally high authorities: one asserting that a downward spinal current dilates and an upward one contracts the vessels of the cord, while another strenuously insists that upward currents contract the vessels and downward currents dilate them. The same line of reasoning that has here been given in regard to the sympathetic nerve applies to the spinal cord. The infinitely weak current formed between a silver grooved director and a pair of iron forceps, moistened with the fluid of the body, will induce when applied to the bared cord very distinct evidences of functional excitement, in the form of spasms; and yet no current I have ever been able to apply to the spine in patients has caused a tremor in the muscles other than those of the back. If spinal currents do good directly, I conceive it must be by an action upon the nerve-peripheries; for it is entirely possible that such an action may affect the nutrition of the cord. Moreover, in some of the diseases in which the measure has been practised with most success, the very great power of the emotions is notorious; and I conceive electricity often cures by acting on the mental or the moral nature. Of course the cure may be no less real and important on this account. In that peculiar affection allied to hysteria, variously known as *spinal irritation*, *spinal anæmia*, etc., I have seen the application of electricity to the back of the greatest service. Sometimes a rapidly-interrupted, strong faradic current has appeared to be most effectual; sometimes a moderate, continuous chemical current has best suited the case. In *spinal congestion*, and in *chronic spinal inflammations* of all forms, I have used downward chemical currents in a large number of cases, but in every instance other measures were at the same time employed, and only in a very few cases has there been any definite evidence of the galvanism being of any service. From ten to twenty-five cells may be employed, the positive pole being applied for fifteen to twenty minutes upon the nape of the neck, and the negative over the coccyx or on the centre of the lumbar vertebrae.

It has recently been shown that galvanism has some tonic powers, and may be used as such in cases of simple debility or nervous exhaustion without any definite lesions. From what we know of its physiological action, it is reasonable to suppose that the force must be able to modify the circulation of every part that has muscular fibres in itself or in its blood-vessels; and such parts constitute the great bulk of the body. It has also been shown by Dr. S. Weir Mitchell that it is capable of temporarily elevating the general bodily temperature. Whether its action is solely by modifying the circulation and causing muscular contractions, or whether it has also a more direct influence upon the nutritive cell actions, is uncertain. Beard and Rockwell* employ two

* A Practical Treatise on the Medical and Surgical Uses of Electricity New York Wm. Wood & Co., 1875.

methods of application, which they denominate general faradization and central galvanization, as follows:

General Faradization.—In practising this, the patient should put the feet upon a copper plate, which serves as one electrode, or should have a large, moistened sponge placed over the coccyx, while a large sponge electrode is passed over the surface of the body. The movable electrode should be first placed upon the forehead, then back of the ears, a mild current being used. It may then be pressed firmly over the sixth and seventh cervical vertebrae, and a powerful current employed; then it should be passed to the posterior cervical triangle just by the posterior border of the sterno-cleido-mastoid muscle; then to the middle of the spine, where very strong currents are usually well borne; then down the chest to the pit of the stomach, and finally to the extremities. Beard and Rockwell give the following as the usual length and proportion of the séance: head, one minute; neck and cervical spine, four minutes; back, three minutes; abdomen, three minutes; upper and lower extremities, four minutes.

In employing this method, at first the currents should not be too powerful, afterwards they should be made as strong as can be borne without pain. The séances should be held two or three times a week.

Central Galvanization.—"The object in central galvanization is to bring the whole central nervous system—the brain, sympathetic and spinal cord, as well as the pneumogastric and depressor nerves—under the influence of the galvanic current. One pole (usually the negative) is placed at the epigastrium, while the other is passed over the forehead and top of the head, by the inner borders of the sterno-cleido-mastoid muscles, from the mastoid fossa to the sternum, at the nape of the neck, and down the entire length of the spine." In applying the pole to the head, the hair should be wetted, or, if this be objected to, the application should be made to the top of the head, locally dampened, and over the prominences back of the ears. Care should be taken not to interrupt the current, and in increasing it to use the rheostat no oftener than is absolutely necessary. The séance should be repeated twice or three times a week, and should be arranged as follows: head, one to two minutes (six to eight cells); neck, both sides, one to five minutes (ten to fifteen cells); back, three to six minutes (ten to thirty cells).

In regard to the choice of these plans, Beard and Rockwell affirm that general faradization is to be preferred where great muscular debility exists; central galvanization where there is rather a nervous exhaustion, as in *hysteria* and *chorea*, *hypochondriasis*, etc. In many cases the best effects are to be obtained by alternating the modes of application, either from day to day or from week to week.

My own experience leads me to prefer decidedly the faradic current as a tonic. I believe that when properly used it does increase the activity of the circulation, probably by an influence upon the smaller vessels: it is further possible that it has a direct as well as an indirect

influence upon the chemical movements of the general tissues. In order to get the best results, the séance should last from forty minutes to an hour, and should be divided into two parts. Thirty to forty minutes should be occupied in the first part, during which the effort is to bring into contraction all the muscles of the body. The current used should be a slowly-interrupted one, of such strength as to produce powerful muscular contractions. Beginning at one or other of the extremities, and bearing constantly in mind the position of the motor points, the operator should go over the whole body, not forgetting the muscles of the chest, back, and abdomen. When the muscular system is sluggish the poles should be brought near enough to one another to bring the desired response. A plan which I have sometimes adopted with good results is to affix a large stationary electrode to the feet, or during part of the séance to the coccygeal region, and then to apply slowly and successively a smaller electrode to the motor points of the various muscles of the upper extremities, neck, trunk, and lower extremities; also to place for longer periods one electrode over the larger abdominal viscera.

MAGNETISM.

Various clinicians claim that they have obtained extraordinary therapeutic results from the use of magnets, but in an elaborate investigation made by Dr. Fred. Peterson and A. E. Kennelly with magnets of enormous power upon blood, frogs, dogs, and human beings it was conclusively shown that magnetism has no demonstrable effect upon any portion of the animal; and it must be concluded that the therapeutic effect of magnets is confined to their psychical influence (*New York Med. Journ.*, vol. lvi., 1892).

PART II.

DRUGS.

A SKETCH OF THEIR NATURAL HISTORY AND PHARMACEUTICAL PREPARATIONS, WITH AN EXHAUSTIVE STUDY OF THEIR PHYSIOLOGICAL, THERAPEUTICAL, AND TOXICOLOGICAL ACTIONS.

PRELIMINARY CONSIDERATIONS.

ALTHOUGH PHARMACY, or the science of preparing medicines, is entirely distinct from THERAPEUTICS, or the science of the application of medicines to the cure of disease, it is evident that some acquaintance with the former is necessary to the correct appreciation of the latter. Further, the basis of each of these studies is a knowledge of MATERIA MEDICA, or the substances used as medicines. PHARMACOLOGY is the general term employed to embrace these three divisions.

In every civilized country there is some recognized official list of drugs and their preparations, known as the *Pharmacopœia*. In most places, this, being prepared with the sanction of the government, partakes of the nature of a law, but in the United States conformity to it depends upon the voluntary action of the professions of Medicine and Pharmacy, by a representative convention of which it was originally prepared and is decennially revised.

The preparations made from crude drugs are as follows:

DECOCTA.—*Decoctions* are made by boiling crude drugs for a greater or less time in water. It is evident that this method of preparing is ineligible when the active principle is volatile or is easily decomposed by heat, or when the drug contains much starch, whose extraction would make the preparation very thick and predispose it to rapid decomposition. The method is especially adapted to hard, woody sub-

stances, and to those containing much albumen, which is coagulated by the boiling water and left in the original drug.

INFUSA.—*Infusions* are made with water, either cold or hot, without boiling. They are prepared by maceration or by displacement.

LIQUORES.—*Solutions* are preparations in which an active, *non-volatile* principle is dissolved in water.

AQUÆ.—*Waters* are solutions of *volatile* principles in water.

MISTURÆ.—*Mixtures* are preparations in which one or more medicinal substances are held in suspension in water. Of such nature are emulsions, in which some oily material is suspended by a gummy or an albuminous body.

MUCILAGINES.—*Mucilages* are solutions of gummy substances in water.

SYRUP.—*Syrups* are sugary liquids, the menstruum or basis of which is water, with, in some cases, vinegar or alcohol.

MELLITA.—*Honeys* are preparations whose basis is honey.

ACETÆ.—*Vinegars* are preparations in which vinegar or dilute acetic acid is used as the menstruum.

TINCTURÆ.—*Tinctures* are alcoholic solutions prepared by maceration or displacement from the crude drug, or by dissolving *non-volatile* principles. In some of them strong, in others dilute, alcohol is used.

SPIRITUS.—*Spirits* are alcoholic solutions of *volatile* principles, made by direct solution or by distillation from the crude drugs.

VINA.—*Wines* are preparations whose menstruum is wine.

GLYCERITA.—*Glycerites* are preparations in which glycerin is the solvent.

OLEA DESTILLATA.—*Volatile, distilled, or ethereal oils* are active principles obtained from plants by distillation or by other processes. They have no chemical relations with fixed oils, and are readily to be distinguished by the fact that the stain which they leave upon paper disappears in a little time. They are usually composed either of carbon and hydrogen, or of carbon, hydrogen, and oxygen, to which, in the case of certain bad-smelling oils, sulphur is added. By oxidation they are converted into resinous compounds. They are all inflammable, usually of powerful odor, commonly, but not in all instances, lighter than water, slightly soluble in water, and freely soluble in petroleum benzin. By the destructive distillation of various organic substances are obtained products resembling somewhat volatile oils. These are the so-called *empyreumatic oils*.

OLEATA.—*Oleates* are solutions of definite principles in oleic acid.

OLEORESINÆ.—*Oleoresins* are concentrated preparations, composed generally of a volatile oil and a resin. They are really ethereal extracts, made by the action of ether upon the crude drugs; in the case of ginger, a mixture of alcohol and ether is used.

SUCCI.—*Fresh juices* are obtained by expression of the green plant, enough alcohol being added to preserve them.

EXTRACTA.—*Solid extracts* are of two kinds; one being prepared by the evaporation of the fresh juice, the other being made in various ways from the crude drug.

EXTRACTA FLUIDA.—*Fluid extracts* are very concentrated fluid preparations, generally so made that one minim represents one grain of the crude drug.

RESINÆ.—*Resins* are peculiar solid vegetable active principles, soluble in alcohol and insoluble in water, most of which are obtained by the precipitation of saturated tinctures with water. The majority of the officinal resins are purgatives.

CONFECTIONES.—*Confections* are medicinal substances beaten up with sugar into a pasty mass.

TROCHISCI.—*Troches*, or *lozenges*, are gummy pellets or disks, so made as to dissolve slowly in the mouth.

SUPPOSITORIA.—*Suppositories* are conical bodies, prepared for introduction into the rectum, where they melt with the heat of the body. Their basis is generally cacao butter.

UNGUENTA and CERATA.—*Ointments* and *Cerates* are fatty solid preparations for external use. The cerates containing wax (*cera*) are the firmer of the two.

EMPLASTRA.—*Plasters* are solid substances spread by the aid of heat upon muslin, skin, or other similar material, and of such nature as to be adhesive at the temperature of the body.

CHARTÆ.—*Papers* are medicated leaves or sheets of paper for external use. The only officinal papers are those of mustard, of nitrate of potassium, and of cantharides.

LINIMENTA.—*Liniments* are liquid preparations, generally soapy or oily, and always intended to be applied externally by rubbing.

The names of **PILULÆ** (*Pills*) and **PULVERES** (*Powders*) sufficiently indicate the character of the preparations.

The effects of medicine are commonly divided into the *primary* and the *secondary*, or the *immediate* and the *remote*. An example will probably show the difference between these in the briefest and most forcible manner. Thus, the immediate effect of a diuretic is increased urination; the secondary effect may be removal of serous effusion in some part of the body. It is evident that the latter is brought about not by the medicine itself, but by the changes it induces; the increased excretion causing a diminution of the amount of the fluid in the blood-vessels, which in turn leads to absorption.

The term or expression *indication* for a given remedy, being in constant use, ought to be distinctly understood; by it is meant the pointings of nature, or, in other words, the evident needs of the system. Thus, hard feces collected in the colon are an indication for a purgative of such character as will produce watery secretions to soften them. Relaxation in a part indicates a remedy that will awaken into new life the natural contractility of the part,—i.e., an astringent. Again, the

suppression of secretion from over-excitation, or from irritation, is an indication for some drug which will allay irritation; while the same suppression, when dependent upon torpor or loss of cell-activity, will call for an excitant,—an irritant. The childish absurdity of treating symptoms by any such law as "*similia similibus curantur*" or "*dissimilia dissimilibus curantur*" is at once apparent. The same symptoms may be the result of absolutely antagonistic conditions and require absolutely opposite treatment. Without occupying space with details, one example will suffice. Either irritation or depression of the stomach may cause vomiting. Therefore in one case of vomiting a stomachic stimulant such as ipecacuanha, which when given freely in health will produce vomiting, may relieve the nausea because the depressed stomach needs a stimulation to bring it to the normal level; in another case a stomach which rejects food because it is irritated needs a sedative like bismuth, which in health will not produce vomiting. In the first case the law of similars seems to hold good, in the second the law of dissimilars appears to be dominant. A law of nature has no exceptions. If an alleged law of nature has exceptions it is not a law. If it were proved that under certain circumstances the earth without the intervention of any second force repels bodies, we should know that the alleged law of gravity is not a law. It is plain, therefore, that neither of the alleged therapeutic laws of similars or of dissimilars is, in truth, a law. They are the results of coincidence, the expressions of half truths. Symptoms are, indeed, but the surface-play of disease, and the rational therapist always seeks their hidden meaning. The conscientious physician refuses to practise upon homoeopathic, allopathic, or any other restricted basis, but gleans therapeutic knowledge from all sources, guiding himself as far as may be by the light of reason and science, but hesitating not to go beyond into the region of the unknown and uncertain when distinctly led by the lantern of empiricism.

By far the greater number of remedies are absorbed into the blood, and thus find access to the part upon which they act. It is necessary, therefore, for them to be so placed that they can be taken into the blood-vessels.

There are five paths of entrance for medicines into the circulation.—the stomach, the cellular tissue, the rectum, the skin, and the lungs. By far the most frequently employed of these is the *stomach*. It is evident that, in order to pass rapidly and readily into the absorbents, medicines must be in solution. When administered by the stomach, however, it is equally plain that solubility in an ordinary menstruum, such as water, is not a *sine quid non*, since the varying acidities, alkalinities, and organic contents of the alimentary juices give to them a solvent power far above that of less complex and varying fluids. Thus, a medicine insoluble in water may be dissolved by the acids of the gastric juices, while another drug may owe its activity to its solution by the alkalies or by the fatty matters of the intestinal fluids.

The dissolving power of the *rectal fluids* is very slight: hence, in order to act efficiently, medicines when given by the rectum must be in solution or be readily soluble. Absorption, moreover, does not occur so rapidly from the rectum as from the stomach, and a longer time is therefore needed to impress the system in this way. In the great majority of cases medicines are thus exhibited to obtain peculiar effects more or less local in character. Thus, an opium suppository is given in dysentery, or to quiet irritation of the genito-urinary organs.

Medicines which are thrown into the *subcutaneous tissue* are said to be administered hypodermically. The syringe employed is provided with a sharp needle, which must be kept scrupulously clean and free from rust. The medicine must be in perfect solution and not too irritating. The advantages of this method of exhibition are promptness and certainty of action. If twenty minutes be required for the absorption of a certain medicine from the stomach, forty minutes will be usually necessary when it is exhibited by the rectum, and five minutes when it is thrown into the subcutaneous tissue. The objections to the hypodermic method are, first, the danger of producing local inflammation and abscesses; second, the possibility of throwing the whole mass directly into a vein and having it swept in concentrated form into the heart or nerve-centres. I have seen the injection of a sixth of a grain of morphine followed inside of a minute by complete unconsciousness, collapse, arrest of respiration, dropping of the jaw, and apparent death. The danger of such a mischance can be greatly lessened by withdrawing the point of the needle an eighth of an inch, after it has been plunged into the tissue. The local irritation produced by hypodermic injections has not only very frequently produced abscesses, but in not a few cases has caused fatal tetanus. Excessive irritation can be largely prevented by certain precautions, but there are many medicinal substances whose hypodermic employment might be advantageous were they not too irritant for such use. In all cases solution must be complete, and if the medicinal substance be of such nature that it is liable to be precipitated by alkalies, an excess of acid should be present in the water to prevent precipitation by the juices of the cellular tissue. An irritant which is rapidly taken up from the part may produce at first smarting and pain without creating any permanent irritation, but a small solid particle lying in the cellular tissue is almost sure to cause inflammation and abscess. All hypodermic injections should, therefore, be filtered before being used. It is of the utmost importance, even when a non-irritating substance is employed, that the injection should be absolutely antiseptic. No solution which has undergone any decomposition or contains any growth should be used at all. Ordinarily the solution should be freshly made. It should always be prepared with boiled or distilled water, and should usually have added to it half a drop of carbolic acid. This amount of carbolic acid when thrown into the cellular tissue, so far from increasing the irritation, has a distinct power of relieving pain by

virtue of its local anæsthetic influence; it also tends to prevent abscess, and has no perceptible effect upon the general system. When hypodermic solutions are intended to be kept, they should contain ten per cent of carbolic acid with a drop or two of glycerin to every fifteen minims, which is the maximum amount that should be injected at one time. A considerable proportion of glycerin will throw out of solution most of the alkaloids, but when solution of the medicinal substance is distinctly favored by glycerin, as is the case with extracts, three or four drops of the glycerin should be added to the hypodermic solution. Not only the hypodermic needle but the whole syringe should be carefully disinfected before use with a strong solution of carbolic acid or other similar agent. The local influence of the injection is also influenced by the method in which it is given. If it be thrown directly under the skin, it may by raising and tearing the skin from its attachment, so interfere with the supply of blood as to cause local irritation. The injection should, therefore, always be thrown deeply into the tissues, where it may diffuse itself. The arm, leg, or any other fleshy portion of the body may be selected, but there is reason for believing that the best place of injection is the buttocks, about one and one-half inches behind the great trochanter.

There are several ways in which medicinal principles are introduced through the skin, although the only one in common use is the application of medicated fatty preparations, either with or without friction. Absorption takes place, of course, most rapidly at those places where the skin is thinnest,—the inside of the thighs, the surface of the abdomen, and especially the armpits. Almost the only remedy which in practical medicine is introduced into the system in this way is mercury. Absorption will take place through the skin from baths, but so slowly that this method is never made use of in the constitutional treatment of disease,—unless the sulphur baths, sometimes employed in rheumatism, impress the general system by absorption, which seems to me doubtful. Formerly, medicines were sometimes exhibited by placing them on blistered surfaces, *beneath* the raised cuticle; but, except in the instance of morphia, so much used in gastric disturbance, at present the *endermic* method is very rarely employed.

In order for a medicine to be absorbed through the lungs in sufficient quantity to affect the general system it must be in the form of vapor or gas.

For *local* purposes medicines are applied to various parts,—to the skin, to the ear, nares, fauces, stomach, larynx, lungs, rectum, vagina, urethra, etc. For the last three, liquid preparations known as *injections*, or solid ones known as *suppositories*, or, in case of the urethra, as *bougies*, or sometimes as *urethral suppositories*, are employed.

For the purpose of making local applications to the respiratory organs, *atomization* is very commonly practised. Many forms of apparatus are in use, but the principle in all of them is the same. A

rapid current of air, or of steam, is forcibly ejected from a horizontal pipe, through a capillary orifice, directly across a similar opening in a vertical tube. The rush of the vapor over this second orifice forms a vacuum; the fluid into which the base of the vertical tube is set, rushing up to fill this, is sucked or drawn out through the orifice, and as it emerges is broken into a fine spray, and is carried along by the current of air or steam into a mouth-piece, at which sits the patient. It cannot be gainsaid that in this way we are able to carry medicinal substances not merely into the larynx, but into the lungs themselves. Volatile medicines vaporized by heat are also sometimes employed in the treatment of lung-affections.

There are various classes of agencies which so modify the action of drugs as to necessitate their consideration. Such are disease, climate, habit, temperament, idiosyncrasies, sex, age, time of administration, and emotions.

Disease often fortifies the system against the action of remedies, so that the dose has to be greatly increased to obtain perceptible effects. Thus, pain or delirium tremens will interfere greatly with the production of narcotism by opium; or spinal disease with purgation. Disease may altogether prevent the action of a remedy. In all these cases two rules should never be lost sight of: first, never give the medicine in such doses as would in health cause death; second, always be sure, before giving large amounts, that the remedy will not make matters worse (as a drastic in intussusception).

Climate, by producing physical habits or tendencies in the patient, often greatly influences the proper selection and dose of remedies. It is only necessary to allude to the great consumption of quinine in malarial regions as an example.

Habit—including mode of life—seems to alter, as it were, the very constitution of man. Not only does it give type to disease, by producing habitual plethora, or its opposite, but it also fortifies against the action of single remedies, or whole classes of them. Thus, in the opium-eater, a dose sufficiently large to kill an ordinary man serves only to gratify the cravings of appetite. Again, a man accustomed to one narcotic, as alcohol or opium, loses, to a greater or less degree, his susceptibility to all narcotic influence; and the patient whose bowels require daily to be moved by a cathartic finds that he reacts more and more slowly to medicines of that class. Again, a nervous system blunted by exposure and toil in the open air is far less susceptible to the action of remedies, and requires larger doses to influence it, than does the delicate organization of a woman weakened by indolence and luxury.

Temperaments are peculiarities of organization characterizing classes of individuals; *idiosyncrasies*, peculiarities belonging to single individuals. This is scarcely the place to discuss the subject of temperaments, but it is allowable to state that while the *phlegmatic* person is no more

easily moved by medicinal than by other agencies, the *nervous* individual answers as quickly to the one as to the other. Idiosyncrasies seem at present to be beyond law. They are often very remarkable, and a knowledge of them is most important for the practitioner. Thus, a relative of the author's is thrown into the most alarming fainting-fits by eating even so much butter as would be ordinarily used as a dressing for vegetables at dinner. Some persons are poisoned by the slightest touch of turpentine, others are frightfully salivated by a mere particle of a mercurial. These idiosyncrasies are numerous, cannot be foreseen, and are often very important: hence the necessity, in prescribing for an unfamiliar patient, of always asking as to his or her peculiarities.

Sex modifies all diseases connected with the organs or the process of generation, but it also does more. Woman is more impressionable, less robust, with less power of resisting external agencies, than is man. Consequently, the dose for her should, as a rule, be less than that for him. It is needless to remark here at length on the necessity for abstinence from strongly perturbing remedies during pregnancy or at menstrual periods.

Age, of course, modifies materially the dose. The rule of Dr. Young, the one which is the most practical and generally useful, is to add twelve to the age and divide the age by the result. Thus, a child one year old would require one-thirteenth, one three years old three-fifteenths, of the amount necessary for an adult. Other rules have been invented, but the only one which is at all practical is the following, proposed by Dr. R. O. Cowling (*American Practitioner*, vol. i.):

"The proportionate dose for any age under adult life is represented by the number of the following birthday divided by twenty-four:" *i.e.*, for one year it is $\frac{1}{24} = \frac{1}{12}$; for two years, $\frac{2}{24} = \frac{1}{6}$; for three years, $\frac{3}{24} = \frac{1}{8}$; for five years, $\frac{5}{24} = \frac{1}{5}$; for eleven years, $\frac{11}{24} = \frac{1}{2}$, etc.

Professor Clarke (*Boston Med. and Surg. Journ.*, 1872) has proposed a rule, which, although probably more accurate than either of those given, seems too cumbersome for ordinary purposes. It is based upon relative weights:

"Assuming the average weight of an adult to be one hundred and fifty pounds, for whom an appropriate dose is 1, or one drachm, the dose of most medicines must be increased or diminished in the proportion of the weight of the patient to that number of pounds. This proportion is represented by a fraction whose numerator is the patient's weight and whose denominator is 150. If a child at birth weighs six pounds, the appropriate dose for it would be $\frac{6}{150}$, or $\frac{1}{25}$; if it weighs ten pounds, $\frac{10}{150}$, or $\frac{1}{15}$. A child two years old, weighing twenty pounds, would require $\frac{20}{150}$, or about $\frac{1}{8}$ of an adult dose; or, more precisely, $\frac{1}{12}$. A person whose weight is two hundred pounds should have $\frac{200}{150}$, or $1\frac{1}{3}$ of an average adult dose."

It must never be lost sight of that children bear narcotics very

badly, and that the doses of such remedies for them should always be proportionally smaller than for the adult.

Time of Administration.—Absorption takes place most rapidly in an empty stomach, and consequently, when rapidity of action is desired, the medicine should be given under such circumstances. Thus, a purgative acts soonest when given before breakfast. Substances which are irritating to the stomach should always be administered not only properly diluted, but also when the viscus is filled by a mass of food, which may serve still further to lessen their concentration. Hence such remedies as iodine and arsenic are preferably exhibited after meals. On the other hand, whenever a remedy is especially intended to act on the mucous membrane of the stomach, it should be given when the viscus is empty. Again, some drugs, such as iron, are best dissolved by the acid gastric juice, and it is a matter of some importance to place them in the stomach after eating, when the process of digestion is most vigorous.

Mental Emotion.—Space is wanting to discuss at any length the influence of the imagination upon the action of remedies; and the reader must be referred to the delightful book of Dr. Tuke for illustrations. Suffice it to state that a positive announcement that a remedy will have a certain effect has often a most remarkable influence in producing that effect, especially on persons of nervous organization and of not too great culture to have faith. I have given a hypodermic injection of a grain of morphine to a man, inducing a degree of hypnotism, and the next day, doubling the size of the injection but withdrawing all morphine, have caused a much more intense effect.

ON THE ART OF PRESCRIBING MEDICINES.—In the practical use of remedies, very much depends upon the methods of their combination, and, so far as concerns the reputation of the physician, no little importance is to be attached to the mere prescription-writing. The recipes of the master are very widely seen, and he who is incorrect in the grammar or spelling of his English or Latin, or departs without reason from the traditional forms, lays himself open to ridicule, than which nothing is more damaging. A crooked, bad chirography is the traditional mark of literary fame; but absolute plainness should be a *sine quâ non* in the writer of prescriptions. This should also apply to abbreviations: these should be of such a character as not only to be readily made out, but also to be so evident as to afford no shelter to the apothecary whose carelessness has led to serious error. In the case of alkaloids and other powerful remedies, the chief name at least should be written in full. In writing the prescription, all the ingredients should first be put down, then the number of doses should be decided upon, and the individual amounts of each substance marked *seriatim*. It is a very good custom always to place first upon the list the strongest of the drugs employed. Without further comment, the

following recipes are appended, simply as examples of the method of writing prescriptions: the first two only are given in full, with date, signature, etc.:

JOHN SMITH, Esq.

R Tr. cantharidis, ℥ss;
Tr. ferri chlor., ℥ss.

M.

S.—Fifteen drops three times a day.

July 1, 1888.

S. W. W.

Feniculi, ℥i;
Aquæ bullientis, Oss.

Macerate per horam in vase leviter clauso et cola.

S.—Black Draught. Dose.—A teaspoonful every six hours, until it operates.*

The art of combining remedies is not a difficult one; but in practice certain principles should not be lost sight of. Chief of these are, to prescribe as few remedies as possible, and to use no powerful drug without a very distinct idea of what it is intended to do. Whenever it is desired to give a powerful remedy in increasing doses until its physiological effect is produced, it should always be given by itself. Thus, it may be necessary to give arsenic so as to impress the system, at the same time that iron is indicated; but the two remedies should be given separately, so that the dose of either can be increased or diminished independently of the other.

The principles of combination, formulated below, were long ago

* These prescriptions are printed as usually written, with abbreviations. The full sentences of directions to the apothecary are:—Misco—Misco et fiat emulsio—Fiat emplastrum iii × iv unciarum—Misco et fiat massa in pilulas viginti dividenda—Misco et fiat pulvis sex—Fiat pulvis in chartulas sex dividendus—Misco et fiat pilule duodecim.

enunciated by Dr. Paris, but are to-day as imperative as ever. Medicines are combined :

First. To augment, correct, or modify the action of a medicine. Thus, purgatives act much more kindly when a number of them are united together. The chief reason of this probably is, that as different remedies affect different portions of the gut, the whole intestine is best reached by a union of the diverse substances. It may take an intense irritation of the mucous membrane to purge as actively as does a mild irritation of both the mucous membrane and the muscular coat.

There are powerful medicines which act similarly upon some parts of the organism but dissimilarly upon other parts. By combining such remedies powerful effects can be obtained at the points where the two lines of action cross each other, without influencing to a great extent other portions of the system. Thus, chloral produces sleep by its action upon the brain, and also has a distinct influence upon the heart, but none upon the intestinal tract. Morphine acts upon the brain, and does not influence the heart, but has a powerful effect upon the intestinal tract. By combining chloral and morphine we get an overwhelming conjoined influence upon the brain in producing sleep with the least possible disturbance of the heart and of the intestinal tract.

Secondly. To obtain the joint action of two or more diverse remedies. Thus, in a cough mixture, morphine may be included to quiet the cough, while ipecacuanha and squill (in accordance with the first principle) are added to affect the mucous membrane. The application of this principle requires caution, or the practitioner will be led into that chief abomination, polypharmacy. It is worse than futile to attempt to prescribe for every symptom. It is the underlying cause of the disorder or the understratum of bodily condition which must be sought out and prescribed for simply.

Thirdly. To obtain a special combination which is really a new remedy, or which experience has shown acts almost as a new remedy. Thus, when to iodide of potassium in solution corrosive sublimate is added, a new chemical compound is formed, which experience has shown to be of great value in syphilitic diseases. Griffith's anti-hectic mixture is another instance of the use of chemical changes, the proto-carbonate of iron being formed out of the sulphate of the metal and the carbonate of potassium. In the famous Dover's powder no chemical change occurs, but the ordinary action of opium upon the skin is so enhanced that the combination may be looked upon almost as a new remedy.

Fourthly. To afford a suitable form. Thus, acacia is added to make an emulsion, or confection of rose to make a pill. In the choice of excipients, care should be exercised to select a substance free from medical properties, having no chemical incompatibility with the medicinal agent, and of suitable physical character. Bread-crumbs often make a good basis for pills; but with nitrate of silver they are chemi-

cally incompatible, on account of the chlorides in them. When writing a prescription, the utmost care should be taken to use such excipients that the combination shall not only be attractive to the eye, but also as little repulsive to the palate as may be. Whenever possible, the pill form should be employed with bitter or disagreeable medicines. The pill may be readily coated with silver-foil; tonic pills may be coated with iron by shaking or rolling them in ferri pulvis while soft and sticky. Sugar-coated pills and "compressed pills" are liable to get so hard and insoluble that their use requires caution. In regard to mixtures, flavoring oils should be freely used, and the power of glycerin to conceal the disagreeable taste of many substances should be remembered. The recent introduction of capsules for the administration of nauseous medicines is a pharmaceutical improvement of the first rank. These capsules occur in two forms. *Hard capsules* are prepared to be filled extemporaneously. They can be made large enough to hold ten minims, although this size cannot be easily swallowed by every person without a little training. The soft, flexible capsules are filled by the manufacturing chemists. They can be readily swallowed by most persons up to the size of one drachm. Not only may solid preparations be given in capsules, but also essential oils, volatile liquids, fixed oils, and fluid extracts; indeed, almost any liquid the dose of which is not too large.

Incompatibilities.—In combining remedies, the subject of incompatibilities must never be lost sight of. The kinds of incompatibilities are two in number,—physiological and chemical. The first of these it would require large space to discuss fully, and any one familiar with the text of the book, if possessed of the slightest reasoning powers, can readily make all necessary deductions.

In many works on materia medica long lists of chemical incompatibilities are given in the accounts of individual drugs. These lists have seemed to me useless, as I have never met with a student who could commit and retain them. Moreover, they contain so much matter of no practical use that the valuable portion is hidden out of sight. A certain amount of chemical knowledge is essential to the student, and is not to be taught in a book like the present. He who would ignorantly combine sulphuric acid and a carbonate needs to re-study his chemical text-book. All that I shall do here is to point out certain principles and a few especial reactions. The following rules may serve for a guide:

Soluble salts which can by mutual decomposition form an insoluble compound will undergo such decomposition when they meet in solution, and will precipitate, unless in some very rare instances, in which a double salt is formed.

Soluble salts which are not capable of forming an insoluble salt never precipitate, and rarely undergo decomposition, when they meet in solution.

Mineral acids decompose salts of the weaker (carbonic, acetic, etc.) acids, and form ethers with alcohol and alcoholic preparations.

Alkalies precipitate the alkaloids and the soluble non-alkaline metallic salts.

Glucosides, such as *santonin* and *colocynthin*, should not be prescribed with free acids or emulsin.

Tannic acid and all substances containing it are incompatible with alkaloids and drugs containing them, with albumen and gelatin, and with most soluble metallic salts used in medicine.

Iodine and *iodides* are incompatible with the alkaloids and the substances containing them, as well as with most soluble metallic salts. The *iodide of potassium** should always be prescribed alone, or only in combination with corrosive sublimate (with which it forms a double salt), or with iodine itself.

Tinctures and other *alcoholic preparations* containing resin precipitate the latter when water is added.

Nitrate of silver should always be prescribed alone, or in combination with opium or extract of *hyoscyamus* only. Most vegetable extracts decompose it, and with creasote it is said to make an explosive compound.

Corrosive sublimate is incompatible with almost everything, and should be given in simple syrup: even the compound syrup of *sarsaparilla* is said to decompose it.

Syrup of squill, containing acetic acid, is incompatible with carbonate of ammonium, but not with the chloride.

Acetate and *subacetate of lead* are incompatible with almost everything, but are nevertheless frequently used in lotion with opium, the insoluble compound formed being therapeutically active.

Vegetable infusions are generally incompatible with metallic salts.

CLASSIFICATION.—In every treatise on therapeutics some method of arranging the individual drugs is necessary. In earlier editions of this work I stated that no satisfactory classification of drugs seemed possible with the then existent knowledge of the subject. Our acquaintance with therapeutic agents and their action upon the organism has enormously increased in the last two decades, and it has appeared to me that at present we can approach much more closely to a really scientific arrangement than was before possible. I have, therefore, arranged the book in accordance with the scheme directly hereafter set forth. Some of the families as here defined are not thoroughly natural, but most of the groups have much of unity in themselves, and of propriety in their relations. Thus, antispasmodics are little better than a heap of incongruities, but delirifacients are singularly united together and opposed to somnifacients, while antiperiodics, perhaps, ought to be merged in the alteratives, with which through arsenic they are closely related.

* Death has resulted from a prescription containing strychnine and iodide of potassium, all the alkaloid being taken at the last dose.

DIVISION I.—SYSTEMIC REMEDIES, substances which act on the solid or fluid tissues of the body.

DIVISION II.—EXTRANEOUS REMEDIES, substances which are employed to act on secretions, excretions, or other liquid or solid bodies which are not human tissues.

SYSTEMIC REMEDIES.

CLASS I.—GENERAL REMEDIES, drugs which affect the tissues of the body generally or such organized systems as reach all portions of the body.

ORDER I.—Nervines, drugs which affect the nervous system.

ORDER II.—Cardiants, drugs which affect the circulation.

ORDER III.—Nutriants, drugs which affect the nutritive movements of the body.

NERVINES.

A. Medicines which act upon the cerebrum.

B. Medicines which act on the lower or nervo-muscular apparatus.

A.

FAMILY I.—Antispasmodics, feeble cerebral stimulants which are employed for the relief of minor spasms and other nervous symptoms, the result of insufficient nerve-power.

FAMILY II.—Anæsthetics, drugs which are used for the production of anaesthesia.

FAMILY III.—Somnifacients, drugs which when in sufficient doses produce deep sleep without delirium.

FAMILY IV.—Delirifacients, drugs which when in sufficient doses produce delirium, followed by stupor.

B.

FAMILY V.—Excito-motors, drugs which produce violent tetanic spasms.

FAMILY VI.—Depresso-motors, drugs which cause paralysis.

CARDIANTS.

FAMILY I.—Cardiac Stimulants, drugs which increase the arterial pressure.

FAMILY II.—Cardiac Depressants, drugs which lower the arterial pressure.

NUTRIANTS.

FAMILY I.—Astringents, drugs which call into exercise the vital function of contractility.

FAMILY II.—Tonics, drugs which so influence nutrition as to increase the vital power.

FAMILY III.—*Alteratives*, drugs which so modify nutrition as to overcome certain chronic pathological processes.

FAMILY IV.—*Antiperiodics*, drugs which so modify nutrition as to overcome the effects of malarial poisoning.

FAMILY V.—*Antipyretics*, drugs which so modify nutrition as to overcome febrile movements.

CLASS II.—**LOCAL REMEDIES**, drugs which affect one organ or apparatus more or less isolated from the remainder of the body.

FAMILY	I. — <i>Stomachics</i> .*
"	II. — <i>Emetics</i> .
"	III. — <i>Cathartics</i> .
"	IV. — <i>Diuretics</i> .
"	V. — <i>Diaphoretics</i> .
"	VI. — <i>Expectorants</i> .
"	VII. — <i>Emmenagogues</i> .
"	VIII. — <i>Oxytocics</i> .
"	IX. — <i>Sialagogues</i> .
"	X. — <i>Errhines</i> .
"	XI. — <i>Epispastics</i> .
"	XII. — <i>Rubefaciens</i> .
"	XIII. — <i>Escharotics</i> .
"	XIV. — <i>Demulcents</i> .
"	XV. — <i>Emollients</i> .
"	XVI. — <i>Protectives</i> .

EXTRANEOUS REMEDIES.

FAMILY	I. — <i>Antacids</i> .
"	II. — <i>Anthelmintics</i> .
"	III. — <i>Digestants</i> .
"	IV. — <i>Absorbents</i> .
"	V. — <i>Disinfectants</i> .

* The definitions are not given in these families, as they are old and well known and their names show the reader to what organs each applies. It should be stated, however, that the family *stomachics* contains drugs which are used simply as stimulants to the gastrointestinal tract, including, therefore, *Simple Bitters*, so called, and *Aromatics*.

DIVISION I.—SYSTEMIC REMEDIES.

CLASS I.—GENERAL REMEDIES.

ORDER I.—NERVINES.

FAMILY I.—ANTISPASMODICS.

UNDER the name of *Antispasmodics* are grouped in this treatise a number of medicines generally of very feeble powers, but of frequent use. In certain conditions of the nervous system—conditions associated with weakness rather than with simple depression—the nerve-centres appear to be more susceptible than is normal to external impressions, as well as to those impulses which originate in the cerebral centres themselves and are connected with the emotions. As a result of this state, various symptoms arise, of trifling import, but often apparently severe, and always annoying. Such symptoms, in their mildest form, constitute the state of unrest known as *nervousness*; in their severer type they may rise in intensity up to the wildest convulsion of *hysteria*. It is in this class of affections that the so-called antispasmodics are useful. As the condition which they relieve is always associated with weakness, they are often spoken of as “nerve-stimulants.” In regard to most of them there is but little evidence of their increasing power or functional activity when administered to healthy individuals. Some of them act very slightly upon the circulation when given in very large doses, and a few when administered as freely as possible induce slight cerebral symptoms, such as vertigo; but, except camphor and Hoffman’s Anodyne, none are capable of producing serious poisoning. As any theory of the method in which the hysterical convulsion originates—of its immediate cause and the mechanism of its production—would, with our present knowledge, be at best but an ingenious speculation, the safest plan in regard to the action of drugs belonging to the class now under consideration is to accept the teachings of clinical experience as to facts, and to avoid theorizing as to the way in which the results are brought about.

MOSCHUS—MUSK. U.S.

A highly odorous, unctuous substance, obtained from the glands situated just in front of the preputial orifice of the *Moschus moschiferus*, or musk-deer of Thibet. The genuine musk-sac is to be distinguished from imitations of it by the hairs being arranged concentrically around a minute orifice. As it occurs in commerce, musk is very greatly adulterated.

PHYSIOLOGICAL ACTION.—Musk appears to act upon the nervous system simply as a mild stimulant and antispasmodic. Jörg and Sundelin have experimented with it upon healthy men with somewhat contradictory results. According to the first-named observer, twenty grains of it induce exhilaration without lassitude, but, according to the latter authority, may cause giddiness, drowsiness, and lassitude. Both observers noted a slight increase in the frequency of the pulse. It seems to me evident that the action of musk upon the healthy organism is a very feeble and uncertain one. Yet there is considerable clinical evidence that when the nervous system is exhausted it is of service in calming restlessness and equalizing the disturbed balance of nervous power.

THERAPEUTICS.—Musk is at present very little used, but it is strongly recommended by some of the older writers in various spasmodic affections, especially in *hysterical convulsions*. In *hiccough* it has been considered a specific. In my experience, in the crisis of low fevers when the symptoms of nervous exhaustion are extreme and threaten death, musk is a very valuable remedy. Thus, in advanced *typhoid fever* a condition sometimes develops in which the pulse is exceedingly feeble, and the temperature has a tendency to rise to a great height, but yields almost immediately to the use of cold, only, however, to remount as soon as the cold is withdrawn. I have seen musk at such time control the temperature, steady the pulse, and apparently save life. In other cases of advanced fevers the powers of the system entirely give out, and the patient passes into a condition of collapse, with subnormal temperature, and mayhap coma-vigil: this state I have also seen relieved by musk. Many years ago Trousseau recommended musk very highly in the *ataxic pneumonia* of drunkards. In all cases of adynamic pneumonia with wild or muttering delirium musk is a very useful remedy. From ten to fifteen grains of musk (the best attainable) must be given at a dose, preferably by rectal injection, suspended in mucilage. The effect of the single dose lasts about six hours. The dose of the *Tincture of Musk* (*Tinctura Moschi*—5 per cent., U.S.) is from one to two fluidrachms.

CASTOREUM—Castor.—The preputial follicles of the beaver are pyriform sacs, occurring in pairs, and containing an unctuous material,—the *castor*. This is a substance allied to musk in its physical properties,

and apparently also in its medicinal qualities. It is certainly less efficient, however, than musk, and Mr. Alexander (*Pereira's Materia Medica*, American edition, 1866, p. 949) is said to have taken a quarter of an ounce of it without having experienced any effect. It is employed in the same affections as musk, in doses of fifteen to sixty grains, suspended in mucilage. The tincture of the U. S. P. 1870 was stronger in alcohol than in castor.

VALERIANA—VALERIAN. U.S.

The root of the *Valeriana officinalis*, an herbaceous perennial of Great Britain. It consists of a short, yellowish-white rhizome, with numerous fibrous roots, of a bitter taste and peculiar odor. The active principle of valerian appears to be the oil of valerian, which, according to Pierlot, consists of a mixture of valerian camphene, valerian camphor, valerianic acid, resin, and water.

PHYSIOLOGICAL PROPERTIES.—Upon cats valerian has a very extraordinary effect, attracting them strongly, and greatly exciting their sexual passions. It is possible that this action is suggestive, due rather to the resemblance of the odor to that of the animals during sexual excitement, than to a direct action of the drug. Valerianic acid given to rabbits in large doses produces, at first, a slight acceleration of the pulse, which, with the respiration, afterwards becomes less frequent than normal, and at the same time lassitude and muscular weakness are developed. Enormous doses kill rabbits somewhat suddenly, or cause fatal gastro-enteritis. According to the experiments of Dr. L. Butte, the extract of valerian has a pronounced effect in checking the destruction of glucose in the blood (*Compt.-Rend. Soc. Biol.*, vol. iii., 1891).

Upon man, large doses (3ii to 3iv) are said to produce a feeling of warmth in the stomach, and sometimes nausea, vomiting, and colicky pains. The pulse is generally slightly quickened, and a sense of exhilaration is induced, accompanied, however, by formication in the hands and feet. Very large amounts cause a feeling of heaviness, and even of pain, in the head.

THERAPEUTICS.—Clinical experience has demonstrated the value of valerian as a means of relief for the milder forms of functional disturbance dependent upon a weak and over-excitabile or an exhausted nervous system. In the state of unrest familiarly known as "nervousness," by soothing and quieting the patient, it will often indirectly procure sleep. In *hysteria* it has been the most frequently used of medicines, and its action is oftentimes most happy. It has also been employed, but with more doubtful advantage, in *mania a potu*, and in the *delirium of adynamic fevers*. In these cases it is almost invariably conjoined with more powerful remedies, and it is very difficult to decide how far it assists in procuring the beneficial result.

ADMINISTRATION.—The best preparations of valerian are the *fluid extract* (*Extractum Valerianæ Fluidum*, U.S.), dose, one fluidrachm;

and the ammoniated tincture (*Tinctura Valerianæ Ammoniata*—20 per cent., U.S.), dose, one to three fluidrachms. The dose of the infusion is a wineglassful; that of the simple tincture (*Tinctura Valerianæ*—20 per cent., U.S.) is one to three fluidrachms.

ACIDUM VALERIANICUM.—*Valerianic Acid* is an oily, colorless liquid, of a caustic taste, and a strong odor, resembling, but differing from, that of valerian. It is made by the action of chromic acid upon amylic alcohol, by a somewhat complicated process, and is employed for the manufacture of *Valerianate of Ammonium* (*Ammonii Valerianas*, U.S.), a white salt occurring in quadrangular plates, which effloresce in a dry and deliquesce in a moist atmosphere, have the odor of valerianic acid and a sharp sweetish taste, and are very soluble in water and in alcohol.

THERAPEUTICS.—Dr. W. E. Parke (*Therap. Gaz.*, 1887, 167) in some experiments in the laboratory of the University of Pennsylvania found that the valerianate of ammonium produces in the frog convulsions followed by general paralysis, both the convulsions and the palsy being due to an action upon the spinal cord. Brought in contact in a concentrated form with any portion of the nerve-tissue, the valerianate produced rapid death of the part. It is very uncertain how far these results were due to the ammonia, and how far to the valerianic acid. They throw no light upon the therapeutic action of the drug, which was originally introduced by M. Déclat, of Paris, as a remedy for *neuralgia*. It has since been used very largely for *nervous headache* and in *hysteria*. It appears to be about equivalent to valerian, but, unless it be in nervous headaches, is less efficient. The dose of it is ten grains, which is generally administered in the form of an *elixir*.

ASAFETIDA.—ASAFETIDA. U.S.

An exudation obtained by incising the living root of the Ferula Narthex, an umbelliferous plant of Afghanistan. It occurs mostly in irregular opaque masses of a dull yellowish- or pinkish-brown, white when freshly broken, of a bitter acrid taste and a strong garlicky odor. Even this *lump asafetida* is largely composed of tears agglutinated together; sometimes these tears are distinct and separate, when they constitute the variety known as *asafetida in tears*. Asafetida is composed chiefly of gum and resin, but its properties are in great part due to the volatile oil, of which it contains from 3.5 to 4.5 per cent.

PHYSIOLOGICAL ACTION.—When taken into the stomach, asafetida acts as a local stimulant and carminative, and on this account is in some parts of the East used as a condiment. The oil is without doubt absorbed. The evidence as to its action upon healthy men is both scanty and contradictory. Thus, while M. Pidoux took half an ounce in a single dose without perceptible effects other than to render his secretions horribly offensive for two days, Jörg and his disciples found that in twenty-grain doses it produced gastric uneasiness and pain with

alvine dejections, increased the pulse-frequency and animal warmth, quickened the respiration, and caused headache, giddiness, and erotic excitement.

THERAPEUTICS.—Clinical experience has abundantly proved that *asa-fetida* is one of the most efficient of the so-called antispasmodics, and may be given to fulfil the same indications as valerian in *functional spasm*, in *hysteria*, and in *nervousness*. It differs from valerian in having a much more decided action upon the mucous membranes. It is an excellent *carminative*, and in the form of injection is constantly used for the relief of *tympanites*. It also in small doses increases the appetite, and affords relief in *dyspepsia*, with flatulent colic and costiveness, of the aged or hysterical. As a *stimulating expectorant and antispasmodic*, it is useful in *whooping-cough* and in *chronic bronchial catarrh*. It is especially efficient in palliating the latter affection as occurring in old people, when the difficulty of breathing is paroxysmally increased by spasm of the bronchial tubes. In *infantile convulsions* and in *severe infantile colic*, *asa-fetida enemata* (f3ii to f3ss of the milk) are exceedingly useful and harmless.

ADMINISTRATION.—The *Pills of Asa-fetida* (*Pilulæ Asa-fetidæ*, U.S.) each contain three grains: from two to four may be given at once.

The dose of the *mixture or milk of asa-fetida* (*Emulsum Asa-fetidæ*—4 per cent., U.S.) is half to one fluidounce; for injections, one to three fluidounces; that of the *tincture* (*Tinctura Asa-fetidæ*—20 per cent., U.S.), half to one fluidrachm. The *suppositories* contain the equivalent of forty minims of the tincture. *Emplastrum Asa-fetidæ* is used externally.

CAMPHORA—CAMPHOR. U.S.

Camphor is obtained in China, Japan, Cochin China, the Sunda Islands, etc., by boiling the comminuted wood of the root, stem, and branches of the *Laurus Camphora*, and skimming off the camphor as it rises to the surface of the water when cooled. This camphor is then partially purified by sublimation, and comes into commerce as *crude camphor*, which is in grains of a whitish or pinkish color, and is finally purified by sublimation with lime.*

Refined camphor (or, as it is commonly called, *camphor*) occurs in disks or hemispherical bowl-like translucent masses, of a fibrous or granular fracture. Its taste is hot and peculiar; its odor very strong and characteristic; it is volatile, inflammable, tough, but readily pulverized on the addition of a few drops of alcohol; melts at 347° F.; is soluble in one thousand parts of cold water,† in one part of strong

* A variety of camphor, as well as of camphor oil, yielded by the *Dryobalanops Camphora*, is very highly valued in the East, but does not reach this country. For a physiological study of it, by Paolo Pellacani, see *Arch. Exper. Pathol. and Pharm.*, xvii. 376.

† By rubbing the gum up with magnesia in water, the latter can be made to take up much more than one part in one thousand.

alcohol, and still more soluble in chloroform; thrown upon water, a granule of camphor floats, and exhibits a rotatory movement.

By slow sublimation at ordinary temperatures, camphor can be made to crystallize in handsome hexagonal tables.

PHYSIOLOGICAL ACTION.—Locally applied, camphor is a decided irritant, although when it is taken into the mouth a sense of coolness after a time is experienced, due no doubt to the volatility of the drug: a precisely analogous phenomenon occurs with some other volatile irritants, such as oil of peppermint.*

Great differences of opinion have prevailed in regard to the action of camphor upon man, and it is scarcely doubtful that it acts differently upon different persons, or at least that doses which in some cause only exhilaration produce general depression in others. When a moderate dose (five to ten grains) of camphor is taken, a feeling of exhilaration is usually induced, a sense of comfort and quietness, especially marked in those previously suffering from "nervousness;" the pulse may be somewhat accelerated, although it is undoubtedly not markedly affected in the majority of cases, and Trousseau saw it fall after the ingestion of ten grains of the drug. After larger doses (twenty to thirty grains) the pulse is usually lowered in frequency, and giddiness, with a feeling of lassitude, is produced, preceded, it may be, by a short period of exhilarative excitement. After poisonous doses (thirty to sixty grains) the symptoms, which are tolerably uniform, are as follows: faintness, headache, vertigo, confusion of ideas, burning pain in the stomach, delirium, violent convulsions, insensibility, general paralysis; a pulse generally small, but sometimes accelerated and sometimes lowered in number; a skin cool, pale or livid, generally bedewed with sweat. Sudden unconsciousness, with or without convulsions, has been in some instances the first manifestation of the action of the poison, and, of course, in any individual case many of the symptoms detailed above may be wanting.†

The only fatal poisonings I know of are: Adult, quantity unknown (*Austral. Med. Journ.*, June, 1888); sickly infant, ten grains; child two years old, unknown amount (*New York Med. Rec.*, March, 1887); fatal abortion produced by three drachms.

Much contradictory evidence might be adduced as to the influence of camphor upon the genital organs. The truth evidently is that its action varies according to the dose and the idiosyncrasies of the patient. In the great majority of instances, I think, camphor in moderate doses has no decided influence upon the sexual system; at least I have seen many hundred such doses taken and have never yet seen any aphro-

* For the physiological action of camphor-cymol, see *Arch. f. Exper. Path. und Therap.* 1873, Bd. 1.

† Cases, *Edinburgh Med. Journal*, May, 1873; *The Clinic*, March, 1873; *Wiener Medicinische Presse*, 1874, p. 258; *Berlin. Klin. Wochens.*, Sept. 1873-74; *Trans. Lond. Clin. Soc.*, 1874, p. 27; *London Lancet*, 1876, ii. 71; *Brit. Med. Journ.*, Feb. 1875, also 1877, i. 607.

disiac effect. In some persons, however, full therapeutic doses are said to cause sexual excitement. In regard to very large doses, the testimony is quite uniform that if they exert any action it is to lessen the erotic feelings.

Camphor acts upon articulates as a violent poison; in birds, according to Menghini, it causes stupor or delirium with epileptiform seizures, in mammals it produces symptoms similar to those seen in man, such as vomiting, violent convulsions, coma, and death, apparently from asphyxia. The convulsions must be of cerebral origin, as, according to the experiments of C. Weidemann (*Arch. f. Exper. Path. und Therap.*, vi. 216) and of Hoffmann (quoted by Weidemann), they do not occur after section of the cord in portions of the body below the point of division.

The cerebral symptoms in camphor-poisoning indicate that the drug has a depressing influence upon the cerebral cortex and that the epileptic convulsions produced by it are probably cortical in their origin, a conclusion which is strongly confirmed by the research of R. Stockman (*Journ. of Physiol.*, vol. ix., 1888), who found that after removal of the cerebral cortex in the rabbit camphor did not produce convulsions. As was first shown by Weidemann, and later by Stockman, toxic doses of camphor in the frog produce paralysis of the motor nerves, the muscles retaining their functional power. That this loss of nerve-power is not the sole cause of the motor disturbance is, however, shown by the fact that spinal reflexes persist in the poisoned frog long after voluntary movements have ceased; and that great lessening of the reflex activity always occurs before the motor nerves show any falling off in their excitability. All investigators are in accord in believing that finally in camphor-poisoning there is centric paralysis of the spinal cord, but both Binz and Grisar (*Archiv f. Exper. Path.*, viii., 1878, and *Centralbl. f. Med. Wissensch.*, 1874) believe that a stage of spinal stimulation precedes the depression. The later experiments of Stockman, however, throw great doubt upon this.

The action of camphor upon the circulation is decided, although our knowledge of it is incomplete. There is reason for believing that the drug acts directly as a stimulant to the heart-muscle, since Heubner has found that camphor is able to excite the heart when arrested by muscarin (*Archiv der Heilkunde*, 1870, ii.), and Heubner, Harnack, and Wittkowski (*Arch. f. Exper. Path.*, v.), Weidemann, Umpfenbach (*Inaug. Diss.*, Erfurt, 1881), Maki, and Stockman all agree in asserting that though the drug decreases the rate it markedly increases the energy of the contractions of the frog's heart. It is true that Alexander Lewin has reached contrary results (*Arch. f. Exper. Path.*, 1890), but these results seem to have been due to his employing too large amounts of the drug. In the mammal toxic doses of camphor lessen the arterial pressure, even after section of the spinal cord. It would appear, therefore, probable that the heart, though first stimulated, is

Afterwards directly depressed by camphor. The action of the drug upon the circulation in the mammal seems to be complicated, and not as yet thoroughly worked out. Heubner failed to get any rise of arterial pressure in rabbits; but in the more extended researches of Weidemann it was found that in the convulsive stage of camphor-poisoning there is a very marked rise of the arterial pressure, which is largely due to the convulsions and disturbances of breathing, as it is in a measure prevented by curarization and artificial respiration. Under these circumstances, however, sudden periodical elevations of the arterial pressure occur. The cause of this phenomenon is not obvious. Stockman found it, at least with Borneo camphor,* to be very inconstant, and Weidemann affirms that it is prevented by section either of the cord or of the vagi. Stockman, as the result of his experiments, concludes that the failure of camphor to elevate the arterial pressure is due to its depressing the vaso-motor centre in the medulla and thereby producing a vascular dilatation which masks the increased action of the heart. This view is somewhat confirmed by the fact that both Maki and Lewin have found that camphor in deeply chloralized animals elevates the blood-pressure. Further investigation is, however, needed before a positive conclusion can be reached.

Although further investigations are necessary to fully establish any conclusion, our present knowledge indicates that camphor in *small dose* directly stimulates the heart and widens the blood-paths by a centric depression, and that in *toxic dose* it depresses both the heart and the arterial system.

According to Stockman, in mammals poisoned with camphor the rate of respiration is very notably increased, but Professor Binz found that in narcotized rabbits camphor greatly increased the activity of the respiration (*Centralb. Klin. Med.*, ix., 1888); and in the experiments of Lewin, in the narcotized rabbits the amount of respired air movement was greatly increased by camphor.

Camphor is undoubtedly very much changed in the organism; the most important of its derivatives is *campho-glycuronic acid*,† discovered in the urine by Schmiedeberg and Meyer (*Zeitschrift f. Physiol. Chem.*, 1881). Glycosuria has been noted by Stockman in camphor-poisoning.

THERAPEUTICS.—Camphor is very largely used internally as an antispasmodic, to quiet restlessness and "nervousness." It is also employed in certain painful affections seen in those persons who are especially liable to the condition of the nervous system just mentioned: thus, it is often useful in *nervous headaches* and *dysmenorrhœa*. Indeed, in the

* Borneo camphor, obtained in Sumatra and Borneo from the *Dryobalanops camphora*, does not reach European commerce, which is also true of the *Ngai camphor* of China. According to the researches of Stockman, the physiological action of these camphors closely resembles that of true camphor.

† For a physiological study of campherol, a derivative of campho-glycuronic acid, see *Archiv f. Exper. Path.*, xvii. 372.

latter disease, either alone or combined with opium in bad cases, it is a most valuable drug, but must be given freely. In *diarrhœa* not dependent upon inflammation, in *cholera*, and even to some extent in *cholera*, camphor is a very efficient remedy, allaying intestinal pain and spasm, and also checking intestinal secretion. It enters into a large proportion of the popular cholera-mixtures. In *cardiac failure* and in *adynamic fevers* it is much used in Germany, but in this country it is very rarely employed either as a cardiac or general stimulant; nevertheless, in the nervous restlessness of adynamic conditions it is very soothing. In *abnormal sexual excitement*, and in *chordee*, large doses of camphor are useful as adjuvants to more powerful remedies. The drug has also been frequently exhibited in various spasmodic affections, such as *whooping-cough*, *epilepsy*, and even *puerperal* and *strychnic convulsions*, but is, I believe, at present never so employed. In *hysterical convulsions*, as in other phenomena of similar origin, camphor is a useful antispasmodic.

Externally, camphor is much used in liniments as a stimulant application for *bruises*, *sprains*, etc.

ADMINISTRATION.—Large doses (ten to fifteen grains) of camphor are best administered in emulsion, because when given in this way, being very finely subdivided, they create as little irritation as possible, and are rapidly absorbed; smaller doses may be given in pill. As an antispasmodic, the *Camphor Water* (*Aqua Camphoræ*— $\frac{1}{8}$ of 1 per cent., U.S.) is usually preferred; its dose is half a fluidounce to two fluid-ounces, but, when a decided effect is desired, the *Spirit of Camphor* (*Spiritus Camphoræ*—10 per cent., U.S.) is more effective; its dose is fifteen to thirty minims. For external use are official the *Linimentum Camphoræ* (camphor one part, cotton-seed oil four parts, U.S.) and the *Linimentum Saponis*, or *Soap Liniment*, U.S.,—a mild liniment, very popular either by itself or as the basis of more stimulating preparations.

OLEUM CAMPHORÆ.—*Oil of Camphor* is the volatile oil of the *Camphora officinarum*. As it occurs in our market, it is a reddish or yellowish-brown liquid, having a strong odor of camphor, and a hot, camphoraceous taste. It contains camphor in solution, and is probably equivalent to it in physiological action, except that it is locally more stimulating, and therefore preferable in intestinal disorders. The dose is five to ten drops.

CAMPHORIC ACID.—This is produced by boiling camphor with concentrated nitric acid. It occurs in small white, acicular or scaly crystals, free from odor, of a feebly acid taste, sparingly soluble in cold, freely in hot, water, also in alcohol, ether, and fatty oils. It was first proposed by Fürbringer (*Berlin. Klin. Wochenschr.*, 1888) as an antiseptic of practical value for the disinfection of the intestinal canal and in the treatment of *tuberculosis* and *ammoniacal cystitis*. During his clinical

experiments the great power of camphoric acid over the *night-sweats* of phthisis was noticed by his assistant, Wittkowski. Max Reichert, Niesel, and other physicians have found the remedy valuable as a local application in the treatment of tubercular and other *catarrhs* of the upper and lower air-passages. According to the studies of Buhland (*Deutsche Archiv f. Klin. Med.*, 1891), camphoric acid is very rapidly eliminated, the whole of a single dose escaping from the kidneys in the course of five hours unaltered. Although Dreesmann and Finkler have investigated the subject to some extent, we are not at present in a position to determine just how camphoric acid arrests excessive sweating, but of the value of the remedy there seems to be no doubt.

In the treatment of *cystitis*, fifteen grains may be given three or four times a day. In cases of *night-sweats*, fifteen to thirty grains may be given at bedtime, or, when the sweat occurs late in the night, the dose may be divided, the patient being awakened to take the last dose after midnight. Gastric irritation and even vomiting have been noted after thirty grains, and Niesel saw in a patient who had taken in four weeks fifty grammes severe renal irritation.

CAMPHORA MONOBROMATA. U.S.—*Monobromated Camphor*, or *Bromated Camphor*.—With iodine and bromine camphor unites to form compounds. According to Laurent, *bromcamphor* occurs in red orthorhombic crystals. These when exposed to the air undergo rapid spontaneous decomposition, but by heating in a closed vessel are resolved into hydrobromic acid, and a compound in which one atom of hydrogen in the camphor has been replaced by bromine. This bromated camphor is a crystalline solid, or occurs in large acicular crystals several inches long.

Our present knowledge of the physiological properties of bromated camphor rests upon the work of Bourneville (*Le Progrès Méd.*, 1874; also *Compt.-Rend.*, Août, 1875), of Lawson (*Practitioner*, 1874, 1875), of Pathault (*Bromure de Camphor*, Paris, 1875), of Richard Peters (*Schmidt's Jahrb.*, Bd. ci. 126), and of Pellicani (*Ibid.*). In frogs there is progressive loss of reflex excitability and of voluntary movement (Peters), which, according to Pellicani, is due to paralysis of the motor nerves. Death is caused by arrest of respiration (Peters). In mammals it produces violent convulsions, muscular weakness passing almost into paralysis, reduction of temperature (after small doses preceded by a rise—Peters), great decrease in the rate of the respiration and of the pulse, with occasional periods of hurried respiration (Peters), profound sleep or stupor, and finally death. Bourneville states that the blood-vessels of the eyes and ears are diminished in calibre. Upon man the drug probably acts as upon other warm-blooded animals; in a case reported by M. Rosenthal (*Schmidt's Jahrb.*, Bd. ci. 127), forty-five grains of it caused tremblings, marked slowing of the pulse, and coma of six hours' duration.

THERAPEUTICS.—Bromated camphor was first introduced by Pro-

fessor Deneffe (*Presse Méd. Belge*, 1871) as a nervous sedative, and as an antispasmodic, especially in *delirium tremens*. It has not, however, sustained its first rapidly acquired reputation, and is little used. I have seen it do good in *spermatorrhœa*, and it may be tried in *chordee*, but especially in *hysteria* and allied convulsive disorders. It is taken with difficulty, and is apt to irritate the stomach. Bourneville proposes the following formula for hypodermic use: Bromated camphor, gr. xlv; Alcohol, f3ix; Glycerin, f3vss; but Lawson states that bromated camphor is so pungent that it cannot be employed hypodermically. The dose of the drug is five to ten grains, given after meals in capsule or coated pill, and repeated as necessary. In Bourneville's experiments twelve grains injected under the skin of a cat caused death in seventy-two hours.

CARBOLATED CAMPHOR.—When fifteen grains of carbolic acid dissolved in an equal quantity of alcohol are rubbed up with thirty-five and a half grains of camphor, an oily, pale-yellow liquid with a feeble odor of camphor results. This does not mix with water or glycerin, but does with almond and olive oil. It has been proposed by Dr. Soulez as a non-irritant, antiseptic dressing for wounds (see *Amer. Journ. Med. Sci.*, July, 1877, or *London Med. Record*, May, 1877).

SUCCINUM—AMBER.

Amber is a fossil resin found on the southern coasts of the Baltic and in other portions of the world. It is not itself officinal or used in medicine, but by destructive distillation yields an empyreumatic oil which is included in the *Materia Medica* list of the U. S. Pharmacopœia.

OLEUM SUCCINI—OIL OF AMBER. U.S.

Oil of amber is an amber-colored liquid, of a hot taste, and a very strong, disagreeable odor. As kept in the shops it is said to be usually sophisticated. It is a powerful local irritant, and has been used as a rubefacient in chronic *rheumatism* and similar disorders. It is also an efficient antispasmodic, and as such is used in *hysteria*, in *whooping-cough*, and in *infantile convulsions*. In the *bronchitis* of infants, with severe nervous symptoms, as well as in the two affections last named, it is very useful as a counter-irritant and nerve-stimulant when diluted with from one to three parts of olive oil and freely applied over the spine. In obstinate *hiccup*, given by the stomach, it is probably, next to musk, the most efficient remedy. Dose, ten to twenty drops, given in emulsion. One tablespoonful caused violent vomiting and diarrhœa, with marked fever and symptoms of general intoxication followed by recovery notwithstanding the fact that the woman aborted (*Viertel-jahrsch. f. Gerichtl. Med.*, xliii.).

SPIRITUS ÆTHERIS COMPOSITUS—COMPOUND SPIRIT OF ETHER.
U.S.

Hoffmann's Anodyne consists of alcohol a pint, ether half a pint, and ethereal oil six fluidrachms. It is a colorless, inflammable liquid, of an aromatic, ethereal odor, and a burning, slightly sweetish taste. Its specific gravity is 0.815. *Hoffmann's anodyne* is sometimes offered for sale without the ethereal oil. Forty drops of the genuine preparation will render a pint of water distinctly milky; but if no oil of wine be present, milkiness will not occur. *Ethereal Oil* (*Oleum Æthereum*, U.S.) is a transparent, nearly colorless, volatile liquid, of a peculiar aromatic odor, and a sharp, bitter taste. Its specific gravity is 0.91. It is *heavy oil of wine*, prepared by the action of an excess of sulphuric acid on alcohol, and diluted with an equal part of strong ether.

PHYSIOLOGICAL AND THERAPEUTIC ACTION.—Dr. H. A. Hare, in studies made in the laboratory of the University of Pennsylvania, found that the *heavy oil of wine* produces, when in moderate dose, a rise in the pulse-rate and in the arterial pressure, followed, if the amount of the poison has been sufficient, by a very remarkable fall in the arterial pressure, and also in the pulse-rate. The rise in the arterial pressure did not occur when the spinal cord had been severed high up, and must, therefore, be in large part, if not altogether, due to a stimulant influence upon the vaso-motor centre. In the period of lowering of pressure the individual heart-beats were extremely full and strong, indicating that the fall of pressure is due to the widening out of the blood-paths by a vaso-motor paralysis. Dr. Hare believes that this paralysis is chiefly peripheral, because he found that the fall was not so great in the dog in which the cord was intact as it was when the cord had been divided. The rapidity of the beat of the isolated frog's heart was at first increased by the drug, but it was not positively determined how far the heavy oil of wine acts in small doses as a cardiac stimulant: that very large doses paralyze the heart by a direct action on the muscle, was indicated by the final diastolic arrest. Careful studies upon frogs by Dr. Hare failed to detect any indication of an action of the oil upon the spinal cord, nerves, or muscles. The toxic properties of the heavy oil of wine are very feeble: 30 cubic centimetres given by the mouth to a small dog weighing twelve pounds failed to produce marked symptoms. It is evident that the small quantity of the heavy oil of wine contained in *Hoffmann's anodyne* can exert no very pronounced influence upon the human system. But it probably has a slight stimulant, calmative effect, since clinical experience indicates that *Hoffmann's anodyne* is more persistent and powerful than an equivalent amount of ether. It is a very efficient carminative, and is also a useful antispasmodic in all the disorders for which such remedies are employed, especially when there is a tendency to failure of the circulation, as in *valvular cardiac disease*. The dose is one or two fluidrachms, repeated in half an hour or an hour, if required, and given in cold water.

HUMULUS—HOPS. U.S.

The strobiles of *Humulus Lupulus*, or the hop-vine, cultivated in northern and middle Europe and in the United States. Hops are soft, greenish cones, one or two inches in length, composed of thin, leaf-like, imbricated scales, having a bitter taste and a heavy narcotic odor. At the bases of the scales is a yellowish powder, officinal under the name of *Lupulinum*. *Lupulin* is in minute grains, and contains, according to Payon, 2 per cent. of volatile oil, 10.30 per cent. of bitter principle, and 50 to 55 per cent. of resin. Volatile oil of hops is yellowish, and has a strong odor of the drug, and an acrid taste. The bitter principle has been obtained by Lermer in brilliant rhombic columns, of an acid reaction.

THERAPEUTICS.—Hops are a bitter tonic, and a very feeble narcotic, producing, when taken very freely, some heaviness, and perhaps sleep. They are especially useful as tonics in cases of nervous irritability requiring medicines of the class. In *delirium tremens* they are very largely used to quiet nervous irritability, to aid more powerful remedies in procuring sleep, and at the same time to strengthen digestion. In *priapism*, in irritation of the bladder, and in abnormal sexual excitement, hops have been exhibited with asserted benefit. They may be tried in large doses, but usually will fail.

Externally, hops are employed in the form of poultices, and when fresh seem to aid the heat and moisture in allaying pain.

ADMINISTRATION.—Dose of the *tincture* (*Tinctura Humuli*—20 per cent., U.S.), half a fluidounce to three fluidounces. For a decided narcotic effect the practitioner may use either the *oleoresin* of *Lupulin* (*Oleoresina Lupulini*, U.S.), dose, ten minims to a fluidrachm, in capsules if desired, or the *fluid extract* (*Extractum Lupulini Fluidum*, U.S.), dose, half a fluidrachm to two fluidrachms.

A *hop poultice* is made by moistening with hot water the hops contained, alone or mixed with an equal part of Indian meal, in a gauze bag of the required size and shape.

LACTUCARIUM. U.S.

The concrete juice of the *Lactuca sativa*,* or garden lettuce, occurs in two forms in our markets. The English variety is in small irregular pieces about the size of a pea; the German, in masses about an inch in length and half an inch in thickness. The color varies from a dark reddish-brown to a light yellowish-brown. The odor is faintly narcotic, the taste bitter. It contains a bitter, crystallizable principle, *Lactucin*.

THERAPEUTICS.—Lactucarium is certainly a very feeble drug. Bouchardat gave half an ounce to a dog, with merely negative results; and in a number of trials made with it some years since I was un-

* For a case of reputed poisoning by *Lactuca virosa*, see *Schmidt's Jahrb.*, Bd. cxxi. p. 137.

able to perceive that it exerted any influence. It has been asserted that it exerts a peculiar soothing, hypnotic influence, like to, but much less intense than, that of opium, and free from its disagreeable after-effects. It may be that the drug varies according to age, time and mode of preparation, etc. Lactucin has been experimented with by Frommüller, who found it proportionately less hypnotic than the crude drug (*Deutsche Klinik*, 1865). The usually assigned dose of lactucarium is thirty grains, that of the *fluid extract* (*Extractum Lactucarii Fluidum*) half a fluidrachm. *Tinctura Lactucarii*, 50 per cent., U.S.; dose, one to two fluidrachms. *Syrupus Lactucarii*, 10 per cent., U.S.; dose, half to one fluidounce. Much larger quantities may be given with little effect.

CIMICIFUGA—BLACK SNAKEROOT. U.S.

The root of *Cimicifuga racemosa*, an indigenous herbaceous plant, growing abundantly in rich, shady woods, attaining a height of six or seven feet, and readily distinguished by its very large multi-compound leaves and its long-branched spikes of whitish polyandrous flowers, naked when open. The root consists of a knotted head, with numerous fine, brittle rootlets; the odor is faint, and the taste bitterish, somewhat astringent and acid. It has not yet been determined exactly upon what the activity of *cimicifuga* depends. Mr. Geo. H. Davis has found in it a volatile oil, which Professor Geo. B. Wood thinks is very probably active, since the virtues of the drug deteriorate on keeping. There are also two resins in the root.

PHYSIOLOGICAL ACTION.—*Cimicifuga* was introduced to the profession by Dr. Young in 1831 (*Amer. Journ. Med. Sci.*, vol. ix.), and Professor Chapman, in his *Elements of Therapeutics*, affirmed that in full doses it causes nausea, more or less general relaxation, vertigo, tremors, and decided reduction of the pulse; while in 1848 Dr. N. S. Davis (*Trans. Amer. Med. Assoc.*, vol. i. p. 351) dwelt very strongly upon its sedative influence. There have been no cases of human poisoning by it. I have seen it, however, when given in large doses produce giddiness with intense headache and general prostration, evidences that it has some influence upon the cerebrum. It also occasionally vomits, but its emetic action is never violent, and is probably simply the result of a gentle irritation of the stomach. Its effects upon the lower animals have been investigated by Dr. Randall Hutchinson (*Therap. Gaz.*, 1887, 731), who finds that in frogs it produces general and complete anaesthesia with loss of reflex activity, voluntary movement being preserved at a time when burning of the feet elicits no pain or motion. As tying the artery of the leg so as to protect the limb from the direct action of the drug on the nerve and muscles did not influence the development of the anaesthesia, this symptom must be due to a paralysis of the sensory side of the spinal cord. Both motor nerves and muscles were found after death functionally active. When the *cimicifuga* was

brought directly in contact either with the isolated frog's heart or with the exposed heart still *in situ*, the movements became slow, and in a little while the muscle was entirely paralyzed. In mammals, *cimicifuga* produced fall in the arterial pressure, with a slowing of the pulse, which was not prevented by previous section of the vagi, and finally diastolic arrest,—facts which prove that the drug is a direct depressant to the heart-muscle or its ganglia. Hutchinson further found that when the arterial pressure is low asphyxia produces no rise, so that it is probable that the vaso-motor centres are also paralyzed. The respirations are affected by *cimicifuga*, becoming slow, altered in rhythm, and suffering final arrest.

THERAPEUTICS.—*Cimicifuga* was originally proposed by Dr. Young as a remedy in *chorea*, and in the simple *chorea* of childhood its value is unquestionable. It must be given freely, and in most cases the simultaneous exhibition of iron and laxatives materially aids it. In acute *inflammatory rheumatism* *cimicifuga* has been highly recommended by Dr. Davis and other practitioners. I have seen it do good, but it is at present very rarely, if ever, used. In *chronic bronchitis* it is sometimes employed with asserted benefit, especially when the expectoration is free and hectic fever exists.

ADMINISTRATION.—As *cimicifuga* deteriorates by keeping, the fresh drug should always be used. The powder (dose, twenty grains) is preferred by some practitioners; but I have found the officinal *fluid extract* (*Extractum Cimicifugæ Fluidum*, U.S.) very active in doses of from twenty minims to a fluidrachm. *Tincture* (*Tinctura Cimicifugæ*—20 per cent., U.S.); dose, one to two fluidrachms. *Extractum Cimicifugæ*, U.S.; dose, five to twenty grains.

FAMILY II.—ANÆSTHETICS.

THE term *Anæsthetics* is here employed as the name of a group of volatile substances, whose vapor has the power of producing loss of consciousness, preceded by or accompanied with loss of sensibility and diminished muscular action. The medicinal properties of these substances are largely due to their volatility, by virtue of which they are very rapidly absorbed and almost as rapidly eliminated by the mucous membrane of the lungs. As a consequence of this, their action is easily controlled. That they are taken into the blood, and thereby reach all portions of the system, has been abundantly proved by recent investigations.*

The action of the anæsthetics certainly is upon the nerve-centres. Thus, Bernard has shown (*loc. cit.*) that a ligature so placed as to cut off all circulation from the posterior part of the frog does not prevent the production of abolition of sensation, voluntary motion, and reflex action in the hind legs when an anæsthetic is injected into the anterior part of the body.

Many of the theories which have been suggested to explain the production of anæsthesia are so groundless that it seems unnecessary to discuss them here. All that are worthy of consideration may, I think, be arranged in four groups, as follows: 1st, those which assert that the symptoms are produced by a partial arrest of oxidation; 2d, those which look upon anæsthesia as due to precedent physical changes in the blood; 3d, those which assert that anæsthesia, like sleep, is due to cerebral anæmia; 4th, those which teach that the various agents employed act directly upon the various organs and tissues concerned, —including in this group the theory of Bernard that anæsthesia is produced by a semi-coagulation of the nervous protoplasm.†

As the theories of the last group are the most natural, the burden of proof rests upon the supporters of the other theories. All the proofs of the first two groups as yet brought forward amount to no more than as follows: that in asphyxia the symptoms are similar to those of anæsthesia; that in profound anæsthesia there is an evident lessening of oxidation; and that some anæsthetics probably produce changes in the blood.

* See especially O. Schmiedeberg, *Inaugural Dissertation*, Dorpat, 1867, *Archiv d. Heilkunde*, viii., 1867; Claude Bernard, *Leçons sur les Anesthésiques*, Paris, 1875.

† For a study of the coagulation theory, see *Centralblatt Med. Wiss.*, 1877, p. 609.

The objections to regarding these facts as proving the truth of the theories alluded to are very grave. Thus, it is very well ascertained that the symptoms of asphyxia are only analogous to those of anaesthesia, not identical,* and indeed that anaesthesia as caused by different agents offers different phenomena; also, there is no proof whatever that the lessened oxidation and the blood-changes which are believed to occur when anaesthetics are employed are causes of the nervous symptoms, and not simply coincident phenomena. It must be insisted on, therefore, that these theories have never been proved. Moreover, positive proof of their incorrectness is not wanting. Thus, in regard to the theory of arrest of oxidation, there are substances, such as nitrite of amyl, which lessen oxidation, but are not anaesthetics; and an excess of oxygen in the air does not lessen the rapidity with which anaesthesia is induced.† The Anaesthetics Committee of the British Medical Association (*Journ. Anat. and Phys.*, xiii. 224) also found that during chloroform-narcosis there was an actual increase in the elimination of carbonic acid. In regard to the blood-theories, Ludimar Hermann (*Reichert's Archiv*, 1866, p. 27) calls attention to the fact that the anaesthetics produce the same general symptoms in the infusoria, which have no red blood, as in mammals; and Lewison‡ has shown that they influence the so-called "salt frog," which contains little or no blood, precisely as they do the normal frog, from which the conclusion is inevitable that they do not affect the frog by altering the nature of the blood or by inducing asphyxia. In regard to cerebral anaemia, it appears to be established that it occurs in sleep; and Claude Bernard (*loc. cit.*, p. 122) has shown that during the period of excitement preceding anaesthesia there is cerebral congestion, but during the anaesthesia cerebral anaemia. Cessation of function normally results in anaemia of the organ, and the anaemia of sleep and anaesthesia is, in all probability, an effect, not a cause, of suspended cerebration. In the frog it has been abundantly proved that absolute anaemia of the nerve-centres does not suspend their functions, and that on the bloodless cerebrum chloroform exerts its usual influence. The only theory at all compatible with our present knowledge is that anaesthesia is in most cases due to a direct action of the agent inducing it upon the cortex cerebri and other nerve-centres.

The action of the anaesthetic upon the nerve-structure is probably a purely vital one. But by no means all authorities acknowledge this. Many, if not all, of the anaesthetics have the power of dissolving the red corpuscles; and Ludimar Hermann (*Reichert's Archiv*, 1866) has pointed out a possible connection between this and anaesthesia. He states that *protophylla*, which constitutes the stroma of the red blood-disks, is an important constituent of the nerve-centres. As death would necessarily occur before the *protophylla* could be dissolved out of

* See Report of Chloroform Committee, *Medico-Chirurg. Trans.*, vol. xlviii. p. 329.

† *Ibid.*, p. 335.

‡ See *Chloral* for further details.

the nerve-centres,—i.e., before it could be dissolved out of the red corpuscles,—it is evident that no extensive destruction of the latter bodies can occur from the action of an anæsthetic and the patient survive. Bilo-acids also dissolve protagon, and Hermann states that some experiments he has made seem to indicate that they have anæsthetic properties. It has been shown by P'ath (*Pester Med.-Chir. Presse*, 1887) and by Strassmann (*Arch. Path. Anat.*, Bd. cxv.)* that chloroform does influence nutrition, and can produce fatty degeneration of internal organs; but there is not at present any sufficient reason for belief in the theories of Bernard or of Hermann. Like other narcotic drugs, the anæsthetics act directly upon the nervous system by virtue of certain inherent relations which at present cannot be explained.

In 1848 (*Archives Gén.*, 2e sér., t. xvi., 1848) Duméril and Demarquay showed that during anæsthesia there is a reduction of temperature. This has been confirmed by Bouisson (*Traité théorique et pratique de la Méthode anesthésique*, Paris, 1850) and by Sulzynski (*Ueber die des Alkohols*, etc., Inaug. Diss., Dorpat, 1865); and Scheinson (*Archiv der Heilkunde*, 1869) asserts that there is no increase in the giving out of heat by the body during anæsthesia, and consequently that the anæsthetics lessen the production of animal heat, no doubt, like alcohol, by checking tissue-metamorphosis. Albumen is not rarely to be found in the urine after anæsthesia, and G. Guerrin states that after anæsthesia by nitrous oxide on the addition of nitric acid an intense rose coloration appears. (*Thèse*, No. 299, Lyons, 1885.)

The action of anæsthetics may be modified by the injection of narcotics. Morphine given hypodermically about half an hour before the exhibition of the anæsthetic is said to have a decided effect in prolonging the anæsthesia. Chloral administered shortly before etherization certainly causes the first stages of the latter to be much quieter than usual, and also prolongs the narcosis.†

The chief purposes for which anæsthetics are used are to *relieve pain* and to *relax spasm*. To meet the first indication they are employed by surgeons especially; but they are also exceedingly valuable in cases of suffering from disease. It must be borne in mind that their action is very transitory and is accompanied by more or less disturbance of the general system, and that consequently they are to be employed only when the pain is exceedingly severe and transient. To relieve pain, anæsthetics are used with great propriety during *child-birth*.‡ In

* Consult also Philip Stommel, *Zur Lehre der fettig. Entartung*, etc. Siegburg, 1889.

† Mr. Bonwill has proposed rapid breathing as a means of producing slight anæsthesia in cases of minor surgery. The patient is required to breathe very rapidly for from three to five minutes, when a condition of partial loss of consciousness, probably dependent upon disturbance of the cerebral circulation, is induced. (*See Phila. Med. Times*, vi. 265.)

‡ I see no reason for believing that anæsthesia of the mother seriously influences the child, and do not think much weight can be attached to the assertions of Dr. Hofmeier (*Berlin. Klin. Wochenschr.*, 1883, xx. 230) that there is produced an increased elimination of nitrogen in the new-born babe.

natural labor it is not commonly necessary to produce complete anaesthesia. When the full effect of either ether or chloroform is induced, there is almost always a weakening, and very often an abolition, of the uterine contractions. The anaesthetic should be administered in such quantities as to relieve the pain without decidedly interfering with the muscular spasm. In certain cases this can be done, in others it is impracticable. I have obtained very advantageous results in some cases by suspending the pains for about half an hour by means of ether, and then entirely withdrawing the anaesthetic. By this treatment the weak, painful, ineffectual efforts of a worn-out, nervous patient may often be converted into regular, successful pains. I think that the risk of *post-partum hemorrhage* is materially increased by anaesthetics, and therefore habitually give after their use two drachms of the fluid extract of ergot, as soon as the perineum is well distended by the child's head.* Anaesthetics are frequently used in surgery for the purpose of relaxing spasm, as in cases of *dislocation*, *hernia*, etc. In medicine, they have been employed in various forms of *convulsions*, and are especially valuable in severe *hysterical convulsions*, in *puerperal eclampsia*, and in *spinal convulsions*; in *epilepsy* they are very rarely called for; in *infantile convulsions* they may be sparingly used when the convulsion itself threatens life. In various *spasms* of the *excretory ducts or canals*, and especially during the passage of *calculi*, they act very favorably, both by relieving pain and by producing relaxation. In *asthma*, and in *spasmodic stricture* of the *oesophagus*, as in all other cases of oft-repeated spasm, they should be administered only to meet temporary indications, as their habitual use is deleterious.

The question as to the propriety of the administration of anaesthetics to persons suffering from organic disease is of the gravest importance, and in individual cases must often be answered with much hesitation. By some practitioners heart-disease is thought to be a positive contra-indication to anaesthetic agents; when, however, the organic disease does not produce any obvious functional derangement of the heart, and when the heart-muscle is in a fair condition of health, ether may be used to the point of anaesthesia, provided the circumstances of the case are such as to justify the surgeon's taking a little risk. When, however, it is possible to avoid the anaesthetic by the use of cocaine or other device, this should be done. It must be remembered that pain or great emotional excitement may arrest at once the movement of a diseased heart. The shock and nerve-strain which attend a major surgical operation without anaesthetics would probably endanger cardiac arrest more than would the anaesthetic used to avoid them. When there is any tendency

* Deaths from anaesthetics are very rare during parturition; it has indeed been asserted that they never occur. This is, however, incorrect. Thus, Dr. C. B. Vanzant (*Chronic Diseases of the Lungs*, vol. xxx., 1893) reports a sudden death from chloroform during a premature labor, and others are on record.

to weak heart, chloroform should never be given; atheroma contra-indicates nitrous oxide.

It appears from the recorded accidents of anæsthesia that the existence of brain-tumors or of other organic brain-disease is of more importance as contra-indicating the use of anæsthetics than is disease of the heart itself. When the brain-arteries are believed to be atheromatous, although no positive signs of organic brain-disease are present, anæsthesia should be induced by the surgeon with the greatest reluctance. Dr. Moxon (*Lancet*, 1886, vol. i.) reports a case in which he believes (probably incorrectly) that a thrombus formed in the coronary artery during insensibility from ether.

Attention has recently been called (*New York Med. Record*, vol. xxxi. p. 199) to the danger which attends the use of ether in Bright's disease. Both Dr. Emmet and Dr. Millard report cases in which collapse with uræmic poisoning rapidly followed the administration of the anæsthetic. The clinical evidence which I have been able to gather together indicates that in patients suffering from renal disease chloroform is preferable to ether unless the heart-muscle has undergone secondary degeneration. This is probably because the amount of chloroform required to produce anæsthesia is so much smaller than that of ether that less strain is thrown upon the excreting organs for its elimination.

NITROGEN MONOXIDE—NITROUS OXIDE. (NO—N₂O.)

Nitrous oxide is a colorless, almost inodorous gas, of a sweetish taste. It is a very active supporter of combustion. Water absorbs nearly its own bulk of it. It is made by the distillation of the nitrate of ammonium, which resolves itself into the gas and water. Thus, $\text{NO}_3\text{NH}_4 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$. Nitrous oxide gas is now supplied in condensed form, or it may be prepared in apparatus best obtained at the dental depots. In using such apparatus the temperature should never be allowed to rise above 482° F., for fear of generating *nitric oxide*.

PHYSIOLOGICAL ACTION.—The inhalation of pure nitrous oxide gas is followed in from a half to three minutes by unconsciousness, which usually comes on quietly, but is sometimes preceded by hilarious, erotic, or pugnacious excitement. During the anæsthesia, the face presents a bloated, swollen, intensely livid appearance. It is probable that the paralysis of nerve function takes the same course as during etherization, but we have little positive knowledge concerning this point. An experiment made by Dr. Amory (*New York Med. Journ.*, August, 1870) indicates that the motor nerves are not affected.

It is well established that nitrous oxide will not support life. A taper will burn in it, it is true, but the liberation of the oxygen is due to the high heat, and at the temperature of the body nitrous oxide is a stable compound. MM. Jolyet and T. Blanche have found (*Archives de Physiologie*, July, 1873) that seeds will not germinate in it, and that animals

(frogs, sparrows, guinea-pigs, rabbits) live no longer in an atmosphere of pure nitrous oxide than in one of nitrogen. Even Dr. Colton, who maintains the absurdity that nitrous oxide produces hyperoxygenation of the blood, states (*The Physiological Action of Nitrous Oxide Gas*, Philadelphia, 1871) that in an atmosphere of the gas a mouse will live only from thirty to sixty seconds, a pigeon from one to two minutes, a kitten from one to two minutes, a frog from thirty to sixty minutes,—all dying of asphyxia.

The French observers above named affirm that nitrous oxide has no direct effect upon the system,—that the phenomena induced are simply due to deprivation of oxygen. The series of facts which they have experimentally proved, and upon which their conclusions are based, are: 1. An animal lives no longer in nitrous oxide than in nitrogen; 2. Anæsthesia occurs at the time that the blood of an animal becomes black; 3. Animals breathing an air containing sixty to eighty per cent. of nitrous oxide and twenty to forty per cent. of oxygen are unaffected; 4. The analysis of the blood of two dogs yielded the following results:

No. 1. Conscious.		No. 2. Unconscious.	
Carbonic acid	. . 46 per cent.	Carbonic acid	. . 36.6 per cent.
Nitrous oxide	. . 29 per cent.	Nitrous oxide	. . 34.6 per cent.
Oxygen	. . . 19.7 per cent.	Oxygen	. . . 3.3 per cent.

and other analyses showed that the coma was not developed until the oxygen in the blood was reduced to three or four per cent.* It is evident that if the above analyses are, as from their reports they appear to be, reliable, the anæsthesia is not due to the presence of carbonic acid in the liquor sanguinis, since nearly ten per cent. more of that gas was present in the blood of the conscious (No. 1) than in that of the unconscious dog (No. 2), and also that it is more rational to believe the decrease in the oxygen, rather than the slight increase in the amount of the nitrous oxide, made the difference between consciousness and unconsciousness. In conformity with this, Dr. Amory's experiments are most interesting. He found that during nitrous oxide narcosis the amount of carbonic acid exhaled from the lungs is only two-thirds of that eliminated before the inhalation, and that immediately after the recovery of consciousness less than one-third the normal amount of carbonic acid is given off.

Again, Mr. Elihu Thomson (*Phila. Med. Times*, Nov. 15, 1873) found that animals in an atmosphere of hydrogen and nitrogen, and also in vacuo, suffered symptoms precisely similar to those caused by the inhalation of pure nitrous oxide; also, that in man the inhalation of pure nitrogen causes the symptoms of nitrous oxide narcosis; finally, that

* These results are closely akin to those obtained by Gréhant, who found that in animals narcotised with a mixture of carbonic acid and air, the gas of the blood contained 95.4 per cent. of carbonic acid (*Compt.-Rend. Soc. Biolog.*, 1837).

nitrogen, hydrogen, and nitrous oxide, as well as a vacuum, are rendered capable of supporting life by the introduction of a proportion of oxygen approaching that existing in common air. Dr. C. A. MacMunn (*The Spectroscope in Medicine*, London, 1880, pp. 73-75) finds that when an animal is killed by nitrous oxide the arterial blood gives only spectrum lines of reduced hæmoglobin, while after death from chloroform the lines of oxyhæmoglobin are very apparent.

On the other hand, it has been asserted that nitrous oxide does not act as an asphyxiant, because the circulatory phenomena produced by it are usually different from those of mechanical asphyxia. It must, however, be borne in mind that the phenomena of mechanical asphyxia are largely due to the presence of an excess of carbonic acid in the blood, whilst in the asphyxia produced by nitrous oxide there is no excess of carbonic acid, so that the phenomena present are simply the outcome of a lack of oxygen. It is, therefore, *a priori*, to be expected that the symptoms of mechanical and of nitrous oxide asphyxia should differ to a certain extent. In an elaborate series of experiments I found (*Therap. Gaz.*, Aug. 1890) that the inhalation of nitrous oxide is usually followed by a rise of the arterial pressure, accompanied by a great disturbance of the pulse; the pulse at first becoming irregular and tumultuous, but by and by settling, so that when anaesthesia is complete the pulse-wave is remarkably large and full, and the rate very slow. The rise and fall of the arterial pressure in nitrous oxide anaesthesia was found to vary remarkably, not only in different inhalations, but at different periods of the same inhalation. Sometimes the rise was sudden, sometimes it was slow and gradual; sometimes it was maintained until near death, sometimes it was interrupted very early; sometimes it was not very well marked, sometimes it was enormous. Dr. Amory has found, in experiments with the cerebrometer upon the dog, that there is, during the anaesthesia, increased blood-pressure in the cerebrum, with stasis in the capillaries. These results show that the circulatory phenomena produced by nitrous oxide resemble those of mechanical asphyxia as closely as could, *a priori*, be expected.

Moreover, I have found that the addition of three per cent. of oxygen nearly doubles the time required for production of anaesthesia, five per cent. increases it more than twelvefold, whilst ten, or even eight, per cent. of oxygen suspends entirely the anaesthetic action in the dog. Again, in a series of experiments (*Dental Cosmos*, May, 1893), I found that two minutes thirteen seconds were required to produce complete anaesthesia with pure nitrous-oxide gas, while in mechanical asphyxia the same result was reached in two minutes nine seconds; also, that three per cent. of oxygen caused the average time required for the production of anaesthesia to lengthen from two minutes and thirteen seconds to four minutes and seventeen seconds, whilst five per cent. of oxygen increased the period to eighteen minutes and fifteen seconds. The evidence seems to me to be complete

and to prove that nitrous oxide acts as an anæsthetic simply by shutting off oxygen.*

Of all the anæsthetics, nitrous oxide is, so far as immediate danger is concerned, the safest. Nitrous oxide is probably administered to seven hundred and fifty thousand persons yearly; and yet there have been only four deaths directly attributable to it with any plausibility. In one of these (*Dental Cosmos*, editorial, June, 1872) it is doubtful whether the gas had anything to do with the fatal result, or, indeed, whether it was really administered. In the second case (*Brit. Journ. Dent. Sci.*, Feb., 1873), death from asphyxia, apparently induced by nitrous oxide, occurred in a healthy man. In the third case, death is asserted to have been produced by apnoea (*Brit. Med. Journ.*, 1877, i. 460). For the

* Paul Bert has shown that a mixture of eighty-five per cent. nitrous oxide and fifteen per cent. oxygen, under a pressure of at least two atmospheres, will produce anæsthesia, and has devised an apparatus which has been used in Paris for the purpose of surgical anæsthesia. The practical objection to the method is its expensiveness, and it has failed to come into vogue. In 1881, Kilkovitch, of St. Petersburg, used with alleged success in parturition Paul Bert's mixture of gases without pressure. His observations have been confirmed by Tittel, E. Cohn, by Swiecicki and Doederlein, from whose reports the conclusion seems to be drawn that the mixture will obtund but not absolutely destroy the pains of labor. In 1888, Witzinger seems to have been the first to have used in major surgical operations the mixed gases without pressure; and in 1889, Gersuny reported eight major operations performed under Bert's anæsthetic. In 1891 (*Amer. Journ. Med. Sci.*, vol. cii.) a serious and able investigation of the subject was made by Dr. Van Arsedale, who employed volumetric mixtures of oxygen and nitrous oxide of different strengths. It was found that in rare cases with fifteen per cent. of oxygen anæsthesia was produced, but usually the loss of consciousness was incomplete and was attended with much muscular rigidity. Afterwards, with ten per cent. of oxygen, usually administered under a certain amount of pressure (about five or six pounds of weight on the reservoir-bag), a moderate amount of anæsthesia was obtained in a number of cases without the production of any cyanosis or disagreeable symptoms. When, however, there was much excitement or fear, the anæsthesia mixture usually failed to produce an effect. The recovery of consciousness was almost immediate, and Van Arsedale seems to be correct in his conclusion that the mixture is a weak anæsthetic, only useful in minor operations. Dr. Frederic Hewitt (*Trans. Odontological Society*, 1891-92) has employed with great satisfaction for the extraction of teeth an ingenious apparatus devised by himself, which enables the operator at will to increase or decrease the amount of oxygen; but in none of his cases was anæsthesia maintained for a length of time, and the conclusions which I reached in the *Dental Cosmos* of May, 1893, by experimentation upon the lower animals, still seem correct. Theoretically, it is possible to get a mixture of oxygen and nitrous oxide which will contain sufficient oxygen to maintain for a length of time the vital functions, and yet have so little oxygen that consciousness will be lost. The zone, however, between unaccompanied loss of upper brain function and loss of respiratory and heart power is such a narrow one that it does not seem to me probable that the surgeon can avail himself practically of the existence of this zone: the danger of passing suddenly from anæsthesia into sensibility, or from partial into complete asphyxia, would always be too imminent.

Carbonic acid gas probably has a direct influence upon the nerve-centres, and it is possible that a dilution of the gas with oxygen would afford a practical anæsthetic mixture. As long ago as 1858, Dr. Osanam, in a communication to the French Academy, stated that he had found a mixture of carbonic acid and air to be a safe anæsthetic. M. Gréhant (*Compt. Rend. Soc. Biol.*, 1887) found that a mixture of oxygen, air, and carbonic acid, so made as to contain 50 parts of air to 100 parts of carbonic acid and 20.8 parts of oxygen, will produce in the rabbit in two minutes a complete anæsthesia which may be maintained for hours, and which disappears in the course of two or three minutes if the animal be allowed to breathe air.

fourth case, see *Ibid.*, 1883, ii. 729. The opinion of Dr. Cartwright (*Lancet*, 1876, 689) and of Dr. W. Ottley (*Ibid.*, 1883, i. 95), that in cases of heart-disease permanent increase of the cardiac weakness is caused by nitrous gas inhalation, is certainly not established. The fall of blood-pressure produced by the gas was found in my experiments to be due to paralysis of the vaso-motor apparatus, and death always occurred from paralysis of the respiratory function, the heart continuing to beat powerfully after respiration had ceased and the arterial pressure had fallen very low. Even when alarming symptoms occur during nitrous oxide anæsthesia, the results are very rarely disastrous, because the loss of function has been due, not to the presence of a poison, but to the absence of oxygen, and although the paralysis may be complete, the life-power sleeps before it dies and is ready to react to oxygen. *Immediate artificial respiration is the one remedy for the treatment of alarming symptoms during nitrous oxide asphyxia.*

Dr. Lafont (*La France Méd.*, vol. i., 1886) has called attention to the possible after-results of nitrous oxide anæsthesia, and among other alleged mishaps mentions miscarriage, chlorosis, epileptic symptoms, and albuminuria. He especially warns against the possible production of diabetes mellitus, and reports a case in which sugar appeared in the urine twice after the use of the gas. He also found sugar in large quantities in his own urine after an inhalation, and was successful in producing glycosuria in the dog. In five experiments made in the University Laboratory by Drs. Geo. S. Woodward and Alfred Hand, the gas failed to produce albuminuria or glycosuria, but Dr. Kenderdine, a well-known Philadelphia surgeon, died some years ago from diabetes, which he persistently attributed to nitrous oxide. Whilst the after-dangers of nitrous oxide are probably not great, the high blood-pressure with venous stasis, which are undoubtedly present during the anæsthesia, strongly indicate that when atheroma or other disease of the arterial walls exist, nitrous oxide is probably a less safe anæsthetic than is ether.*

ETHER—ETHYL OXIDE. ($C_2H_5O-(C_2H_5)_2O$.)

Ether is a colorless, very volatile liquid, obtained by the dehydration of alcohol by sulphuric acid. It is very inflammable, as is also its vapor, which is two and a half times heavier than air. It is freely soluble in alcohol, and is itself a powerful solvent. Its odor is strong and peculiar; its taste is hot. Its specific gravity, when pure, is 0.713, and its boiling-point $95^{\circ} F$.

The U.S. Pharmacopœia formerly recognized ether as official in two forms, *Æther* and *Æther Fortior*; at present it recognizes only one form of ether, under the name of *Æther (Ether)*, and requires that it shall contain ninety-six per cent. by weight of absolute ether and about four per cent. of alcohol containing a little water. It should be noted that

* For fatal apoplexy, following nitrous oxide anæsthesia, see *Dental Cosmos*, 1890.

this preparation corresponds to the *Æther Fortior* of the old Pharmacopœia. The British Pharmacopœia recognizes *Æther*, containing not less than ninety-two per cent. by volume of pure ether, and *Æther Purus* or *Absolute Ether*, giving the specific gravity of the latter preparation as not exceeding 0.720. Ether of the U.S. Pharmacopœia should boil "when a test-tube, containing some broken glass and half filled with it, is held for some time in the hand." U.S.

PHYSIOLOGICAL ACTION.—The first effects of ether when inhaled are burning in the fauces and a feeling of strangulation, both due to the local impression of the irritant vapor. The primary indications of its systemic action are a sense of exhilaration and a lightness in the head, associated with a roaring or buzzing in the ears. These are soon succeeded by a feeling of the immediate surroundings being afar off, which soon fades into semi-unconsciousness, with visions and illusions. These are of various characters, and are often accompanied by a species of delirium. Some patients weep, others laugh; some shout, some pray, some rave, and some become exceedingly pugnacious. In rare instances the dreams become erotic; and cases are on record in which there were distinct evidences of the occurrence of a complete venereal orgasm. In this stage the patient in most cases may be more or less perfectly aroused. There is rarely sufficient anæsthesia for practical purposes before the period of complete unconsciousness.

The second stage of ether-narcosis may be considered to begin with the complete loss of consciousness. Muscular rigidity may persist for a length of time, but usually it soon passes off, and the patient lies relaxed and quiet, with slow, regular, automatic respiration.* The occurrence of stertorous respiration, due to a paresis of the muscles of the palate, shows that the stage of muscular paralysis is being reached. It should, except in rare cases, be the signal for the immediate withdrawal of the anæsthetic.

The face during etherization is reddish; marked pallor and lividity are respectively important indications of failure of the heart's action and failure of respiration. The stage of excitement generally lasts only a few minutes, but in some cases is prolonged, and in nervous women may pass into a violent fit of hysterics, which soon yields, however, to a persistent use of the anæsthetic. The pulse is quickened and increased in force by ether, and it will often maintain itself during a prolonged narcosis. If the vapor of ether be taken in a concentrated form, there is usually in the beginning a momentary arrest of respiration, accompanied by a decided sense of suffocation, evidently the result of the irritant action of the vapor upon the upper air-passages. So soon as this has passed off, the respirations are usually accelerated as well as deepened; but as the stage of anæsthesia is reached they be-

* For a full discussion of motor phenomena during profound anæsthesia, see Rudolf Jauch (*Wien. Med. Wochenschr.*, vol. xxxix., 1899, p. 359).

come slower, and, if the inhalation of the ether be persisted in, they grow not only more and more distant, but also more and more shallow, until they are gradually extinguished. The respiratory phenomena seem to be the same in the lower mammalia as in man. The primary arrest of respiration during the first stages of etherization is undoubtedly due to a local irritation of the mucous membranes of the air-passages. According to Kratschmer (*Sitzungb. Wiener Akad.*, 1870, Abth. ii.), in the rabbit it is prevented by previous section of the trigeminal nerves, but not by division of the vagi; nor does it occur when the ether is administered through a tracheal fistula. This would indicate that the respiratory disturbance is due to irritation of the peripheral trigeminal nerves, but Dr. H. A. Hare (*Univ. Med. Mag.*, vol. i. p. 419) has found that in the dog tracheal irritation with ether produces respiratory arrest, which is, however, prevented by previous section of the vagus. As stated by Dr. P. Knoll (*Sitzungb. Wiener Akad.*, Oct. 1876), the arrest of respiration is sometimes replaced by very irregular breathing. The importance of the matter is increased by the fact that Kratschmer has noticed that the disturbances of respiration are accompanied by spasm of the glottis. It is evident that these disturbances are reflexes due to irritation of the trigeminal nerves in the upper, and of the pneumogastric filaments in the lower respiratory tract. It is possible, but not probable, that some of the accidents which have happened early in human anæsthesia, have been due to these reflexes; the important practical fact is that aberrations of respiration occurring in the beginning of an etherization are to be overcome by persistence in the inhalation, after which the respirations will become slower, deeper, and more regular; indeed, as pointed out by Kronecker (*Corresp. Blatt. Schweizer Aerzte*, 1890), the late and dangerous arrest of respiration during anæsthesia occurs only after the reflex function has been abolished. When the administration is continued to the end, the respirations become very slow and more and more shallow until extinguished. Irregularities of respiration occurring in the later stages of an etherization are of the most serious import, and demand immediate withdrawal of the drug. Clinical experience confirms the experimental proof obtained by Dr. Knoll, that these late disturbances of respiration are the result of the direct influence of the drug upon the respiratory centres.

According to Professor Eulenberg, in the beginning of anæsthesia produced either by ether or by chloroform, the knee jerk in man is increased; but, while this increase soon disappears when chloroform is employed, with ether it endures even into the narcosis (*Hoffmann und Schwalbe Jahrb.*, 1883, p. 117).

Upon the lower animals ether acts as upon man, and it has been shown by Claude Bernard that the most primitive infusoria are susceptible to its influence (*Le Progrès Méd.*, 1876, p. 77).

Nervous System.—As the cerebral functions are the first to be affected, it is very apparent that the brain is especially sensitive to the

narcotic. Flourens (*Comptes-Rendus*, vol. xxiv., 1847, pp. 161, 242, 253, 340) found that, at a certain stage of etherization, pricking of the anterior or motor nerve-roots caused motor disturbance, although the posterior or sensory portions of the spinal centres were completely insensible. After a more prolonged inhalation, the anterior or motor centres also failed to respond to mechanical irritation, although the functions of the medulla oblongata were regularly performed, and stimulation of its anterior centres gave rise to motor disturbance, and pricking of its sensory portions even caused manifestations of pain. When the inhalation of ether was maintained for a sufficient time, the sensory and finally the motor functions of the medulla oblongata were compromised, and death from paralysis of the respiratory centres ensued.

Longet (*Archives Gén.*, 4e sér., tome xiii. p. 374) in part confirms and in part questions the results of Flourens. He states that he has found the sensory functions abolished very early, but has never failed in any stage of the narcosis to get a response from the anterior part of the cord. These apparently different results are simply due to the fact that, while Flourens used only mechanical stimuli, Longet employed powerful galvanic currents.

Flourens was substantially correct, and the order of the involvement of the nerve-centres in man and animals is—first the cerebrum, next the sensory centres of the cord, next the motor centres of the cord, next the sensory centres of the medulla oblongata, and finally the motor centres of the medulla oblongata.

That ether is capable of impressing the nerves seems established by the experiments of Longet (*loc. cit.*, p. 382) and of Serres (*Archives Gén.*, 4e sér., tome xiii. p. 433). These observers found that the direct application of ether to a nerve produced a paralysis of the sensory fibres of that nerve; so that pinching the nerve below the point of application caused no pain, although voluntary movement was preserved, and galvanization of the nerve-trunk above the point of application induced spasms in the tributary muscles: i.e., the power of conducting an impulse downwards was preserved, that of conducting it upwards was lost. By a longer application of the anæsthetic the function of the efferent as well as of the afferent fibres was abolished, temporarily at first, but, if the application were persisted in, permanently. Practically, however, inhaled ether has no influence upon the nerve-trunks, because the nerve-centres are so much more sensitive to its influence that their functional power is abolished before the nerves are affected. Indeed Conly (*Soc. de Biologie*, February 13, 1876) found that in animals killed by ether, chloroform, or chloral, the motor nerves and muscles preserve their function longer than in animals killed by sudden violence.*

* Dr. F. H. Hooper was, I believe, the first to note that stimulation of the recurrent laryngeal nerve causes a dilatation of the glottis in the thoroughly etherized dog, although

Upon the motor system of organic life ether certainly acts, but much less energetically than upon the voluntary system. Thus, after death from ether the vermicular movements of the intestine, although less active than normal, are very rarely, if ever, entirely absent.

Circulation.—The first effect of ether is usually to cause a pronounced rise in the arterial pressure, which is commonly maintained even through a prolonged ether narcosis, and may continue until manifest failure of respiration; commonly, however, it is after a time succeeded by a fall of pressure. According to Sansom (*Chloroform*, Phila., 1866), the vessels of the frog's web are thrown into a persistent spasm by the inhalation of ether; and in the research of Drs. Bowditch and Minot upon mammals (*Boston Med. and Surg. Journ.*, May, 1874), the conclusion was reached that the vaso-motor centres are at first stimulated, and afterwards depressed. Our present evidences show that the action of ether upon the circulation is very similar to that of alcohol; that there is, during ether anesthesia, a rise of pressure, the result in part of increased cardiac action, and in part of vaso-motor centric stimulation; and that this rise is followed by a fall, the outcome of a consentaneous cardiac failure and vaso-motor centric and peripheral paralysis.

It is frequently asserted that ether when added to blood coagulates it. A. Schmidt, however, states that the coagulation is due to ozone which has been generated by the ether and is contained in it, since freshly distilled ether does not coagulate albuminous substances.

The researches of Wittich (*Schmidt's Jahrbücher*, Bd. cxlii. p. 212) and A. Schmidt (*Virchow's Archiv*, vol. xxix., 1864, p. 19) have shown that when ether is added to the blood of horses,* cats, or rats, the red corpuscles disappear in a very short time, and, as their stroma cannot be demonstrated by the aid of reagents, this disappearance is due to its solution. The oxyhæmoglobin thus set free is dissolved in the serum, but the presence of the ether soon causes it to crystallize. There is no proof that these changes occur to any extent when ether is inhaled; and the usual rapid recovery from the effects of the anæsthetic indicates that there is no profound alteration of the blood.

An imperfect study by Harley of the effect of ether on the gases contained in drawn blood indicates that ether does not exert much influence upon their proportional amounts. It is, however, quite possible that a more thorough investigation would give a different result.

in the normal animal it always produces a constriction. This remarkable observation has given rise to several investigations, the most recent and extended of which is that of Prof. H. P. Bowditch (*Amer. Journ. Med. Sci.*, April, 1887), to which the reader is referred for a full summary and discussion of the matter. Dr. Bowditch corroborates the observation of Hooper, and also finds that during partial etherization weak irritation of the recurrent nerves causes dilatation and strong irritation constriction of the glottis. As yet no satisfactory explanation of these curious phenomena has been offered.

* Schmidt (*loc. cit.*, p. 22) says that sometimes crystallization fails in the blood of the horse.

THERAPEUTICS.—For a discussion of the use of ether as an anæsthetic, see page 154.

Administered by the mouth, ether has been used with advantage in various forms of *colic*, but is generally inferior to chloroform. When, however, as in some cases of *retrocedent* or *internal gout*, there is with the painful gastric and intestinal spasm a condition bordering on collapse, the stimulant properties of ether make it very valuable.

In sudden *sinking-spells*, either from poison or from natural causes, ether, as a powerful and very quickly acting stimulant, is often indicated. In some cases of this description it may even be administered by inhalation. Of course, under these circumstances its influence should not be carried nearly to the point of producing anæsthesia.

As an *anthelmintic*, ether has been used by M.M. Bourdier and Lortet with success against the *tapeworm*. For this purpose, an ounce and a half may be administered at once, followed in two hours by a full dose of castor oil.

In *hysteria*, *neuralgia*, *nervous headache*, and *spasmodic neuroses*, such as *hiccough* and *asthma*, ether is occasionally employed with benefit.

When ether is swallowed, it produces a sense of strangulation and choking, which seriously interferes with its use. For this reason, it is best given in capsules, or in ice-cold water. Probably large doses are best administered by putting them, mixed with an equal amount of brandy, on finely-cracked ice before drinking. The dose is from one fluidrachm to half a fluidounce.

Etherization by the rectum has been tried, but has been discarded on account of the severe irritation of the rectum and lower bowel which it causes, as well as because of the slowness of the production of insensibility.

CHLOROFORMUM—CHLOROFORM.

METHENYL CHLORIDE—TERCHLORIDE OF FORMYL.

This substance, which was discovered in 1831 by Mr. Samuel Guthrie, of Sackett's Harbor, New York, is produced by the action of chlorine upon alcohol. It is a colorless, limpid, and neutral fluid, which is for practical purposes non-inflammable, although it can be made to burn with a greenish flame (*Fownes's Chemistry*, Am. ed., 1869, p. 566). Its taste is hot and sweetish, its odor fragrant and peculiar. It is soluble in alcohol and in ether, but when dropped into water it sinks, if pure, as transparent globules without milkiness. The alcoholic solution, when moderately diluted with water, forms an aromatic, sweetish liquid. It is antiseptic, and does not coagulate albumen.

The U.S. Pharmacopœia of 1880 recognized chloroform in two forms, *Chloroformum Venale* or *Commercial Chloroform* and *Chloroformum Purificatum* or *Purified Chloroform*. The Pharmacopœia of 1890 recognizes only Purified Chloroform, under the name of **CHLOROFORMUM** or *Chloro-*

form, and requires that it should contain by weight 99 to 99.4 per cent. of absolute chloroform and 1 to 0.6 per cent. of alcohol.

PHYSIOLOGICAL ACTION.—Although somewhat of an anæsthetic, chloroform applied locally is a powerful irritant. On the skin it produces redness and burning; if the evaporation be restrained, vesication will be induced by it. Taken into the mouth, it causes a burning sensation, and, when swallowed, a sense of warmth in the stomach.

The vapor of chloroform, when inhaled, produces symptoms seemingly similar to those induced by ether, except that the choking sensations are absent, and that the stage of excitement is generally, but not always, shorter and less violent than is that of etherization.

Dr. Snow (*On Anæsthetics*, London, 1858) divides the chloroform narcosis into four degrees or stages, but the division adopted by Sabarth (*Das Chloroform*, Würzburg, 1866) and most writers seems more useful. This classification recognizes three stages. In the first of these, the symptoms are similar to those of alcoholic intoxication. This stage is generally very short, but in athletic persons, and especially in those who have been intemperate, it may be very long and very violent, and may persist after loss of consciousness. In drunkards, this excitement at times cannot be overcome without grave danger to life. During this first stage, although consciousness is not lost, the sensibility is generally blunted, but very rarely is it altogether annulled. Dr. Coleman (*Sansom, Chloroform*, p. 55, Philadelphia, 1866) states, however, that he has extracted his own teeth without pain; and Dr. Snow relates the anecdote of a child who played with his toys during the operation of lithotomy.

During the second stage, which is that of anæsthesia, the consciousness and sensibility are abolished, the muscles are relaxed, and the patient lies perfectly quiet. This is the surgical stage, during which ordinary operations are performed. As already intimated, in some cases the first and second stages are united, so that violent excitement, muscular spasm, and rigidity may coexist with loss of consciousness and of sensibility.

The third stage is one of profound narcosis, with stertorous breathing, intense muscular relaxation, and abolition of ordinary reflex actions.*

* Dr. Baudin (*Le Progrès Méd.*, Sept. 1874) called attention to the pupil as a guide in chloroformization, stating that, although at first it is uniformly dilated, afterwards it is uniformly immovably contracted, and that this is the period for operating. Schläger is in accord with Dr. Baudin; in one hundred and twenty out of one hundred and twenty-two cases observed the pupil was dilated during the stage of excitement, and during complete anæsthesia narrowly contracted. He also states that if during anæsthesia the pupil return to normal, more chloroform is required, but if it suddenly dilate, danger is imminent. At present, however, the condition of the pupil cannot be considered a safe guide in anæsthetization. Dogiel (*Reichert's Archiv für Anat.*, 1886) affirms that in rabbits, during the stage of excitement, the pupil is contracted, during anæsthesia dilated. Professor Schiff has strenuously combated the conclusions of Baudin; and in a very careful series of experiments on animals Dr. W. H. Winslow found that the state of the pupil varies greatly in the same stage of anæsthesia. Thus, in

This is always a condition of danger, and its induction by chloroform, except under very peculiar circumstances, is unjustifiable.

The pulse in the first stage of chloroform-narcosis may be quickened, even apparently strengthened; in the second stage it is generally about normal in frequency, but is more or less weakened; in the third stage it may be rapid and weak. Dr. Noel (*London Med. Record*, 1877, p. 457) calls attention to a cervical venous pulse, most marked in the external jugulars, which he asserts frequently occurs during the waking up from chloroformization. He believes it to be a symptom of serious cardiac embarrassment. E. Simonin found that the temperature usually rises during the first stage ($.1^{\circ}$ – $.8^{\circ}$ C.), falls slightly during the second or remains above normal, and falls decidedly during the third stage (*Centralbl. f. Chirurgie*, 1877, p. 234).

In man the first arrest of respiration, so obvious in etherization, rarely if ever occurs. This is probably in great measure owing to the chloroform vapor, as employed, being much more dilute than the ether vapor. The experiments of Holmgren, Kratschmer, and others have shown that upon the lower animals the respiratory action of chloroform is similar to that of ether (see p. 136), except that it is much more intense.

The action of chloroform on the nervous system, like that of ether, is chiefly upon the brain and the spinal centres. Carter (*Brit. Med. Journ.*, Feb. 1867) found that very decided anæmia of the brain can be seen in animals subjected to its influence after the cerebrum has been laid bare; and accident in man (*Amer. Journ. Med. Sci.*, 1860) has furnished the corroboration of his experiments. As the result of chemical studies, Julius Pohl (*Arch. f. Exp. Pathol. u. Pharm.*, xxviii, 1891) believes that more chloroform exists during the narcotic period in the brain-tissues than in the blood coming to it. Bernstein (*Schmidt's Jahrbucher*, Bd. cxlii, p. 227) has demonstrated that its action on the peripheral nerves is very slight. He found that there was no perceptible difference in the conducting power of the two ischiatic nerves of a frog chloroformed after one of its iliac arteries had been tied. It is doubtful how far the muscular excitement of the second stage is due to real spinal exaltation and how far it arises from other causes. Bort asserts (*Comptes-Rendus*, t. lxiv., 1867) that it is purely psychical, and that there is during the production of anæsthesia a steady lowering of reflex activity. He rests this assertion upon the fact that in animals chloroformed after section of the cord there is no motor disturbance below the point of section,—a fact which certainly demonstrates at least that the muscular excitement and the convulsions are cerebral.

In some animals the first effect of the inhalation of chloroform upon

complete anæsthesia, sometimes the pupil was widely dilated, sometimes contracted; and death sometimes occurred with a dilated, sometimes with a contracted, pupil,—in the former case probably being syncopeal, in the latter asphyxial (*Phil. Med. Times*, vi. 275).

the circulation is a decrease in the frequency of the heart's action. Dogiel believes that this is due to a stimulation of the inhibitory centres, because he has found that it does not occur after section of the vagi. The after-increase in the rapidity of the pulse appears to be due, at least in part, to paralysis of the inhibitory centres, upon which chloroform seems to act as upon the oculo-motor centres, producing in them at first excessive functional activity, but afterwards functional paralysis. Both Kratschmer and Knoll (see p. 139) have noticed in rabbits, when either ether or chloroform is inhaled through the nose, a momentary rise of arterial pressure corresponding to the arrest of respiration, and, like it, evidently produced by irritation of the peripheral trigeminal branches.

As was first proven by the English Chloroform Committee (*Med. Chirurg. Trans.*, vol. xlviii. p. 326), after the first half-minute of the inhalation of chloroform there is a progressive lowering of the arterial pressure. This has been confirmed by all observers and is an established fact. The matter still somewhat in dispute is as to the immediate mechanism of the fall. Sansom and Harley state that there is a spasm of the small vessels, which can be readily seen to occur in the web of the frog during chloroformization. Not until the third stage is reached, according to these authors, do the vessels relax into dilatation. If these observations be correct, chloroform first stimulates and afterwards depresses the vaso-motor centres. In accordance with this are the important experiments of Gaskell and Shore (*British Med. Journ.*, vol. i., 1893), who find that the local application of chloroform to the medulla or its injection into the cerebral artery produces an immediate rise of blood-pressure, usually accompanied by a slowing of the heart, which is followed by a fall of pressure as soon as the chloroform is able to diffuse itself over the circulation. In a further very ingenious series of experiments, Gaskell and Shore so connected the carotid arteries and jugular vein of an animal (A) with the similar vessels of a second animal (B) that the brain of A was fed exclusively with blood from B. It is plain that chloroform given to B would reach the brain of A but would not reach the heart of A. Under these circumstances it was found that chloroform administered to B produced rise of blood-pressure in A. In a second series of experiments the blood-vessels of A were so connected with those of B that when chloroform was administered to B it reached the heart of A and all other portions of the body except the brain. When this was the case, chloroform given to B produced an immediate fall of pressure in A without there having been any rise. In other words, when chloroform reached the vaso-motor centres and not the heart, it caused rise of arterial pressure; when it reached the heart and not the vaso-motor centres, it caused fall of pressure.

The only experiments with which I am acquainted, to which any weight should be attached, as indicating that chloroform primarily paralyzes the vaso-motor centres, are those published as long ago as 1874 by Professors H. P. Bowditch and C. S. Minot (*Boston Med. and*

Surg. Journ., 1874). In these experiments, which were made upon curarized animals, "irritation of the saphena nerve caused a much less marked rise of blood-tension than when the anæsthetic was not used. Sometimes there was absolutely no rise of tension to be observed, while at other times the rise was from one-third to one-half that produced by the same irritation on an animal not subjected to the action of chloroform." Further compression of the carotid in the chloroformed animal did not cause the customary spasm and rise of arterial pressure.

It must be remembered that these experiments of Bowditch and Minot were made at a time when the importance of the subject had not been fully realized; that on the carotid but a single experiment was made; and that there was frequently in the experiments of Bowditch and Minot a great rise of pressure following irritation of the sensitive nerve, though the rise was not as great as in the normal dog. There seems to be no doubt that late in chloroform-poisoning there is a vaso-motor paralysis, and it may very well be that in the single carotid experiment of Bowditch and Minot the chloroformization had been carried on to the fullest extent, whilst the rise of pressure which occurred in many of their chloroformed dogs when the saphena nerve was irritated shows that at such times at least the vaso-motor centres were not paralyzed, though the arterial pressure had fallen very distinctly. The results, therefore, of Bowditch and Minot are not in any way proof of the incorrectness of the theory of Gaskell and Shore; and the drift of the present evidence is to show that chloroform in the *earliest stages of its action stimulates rather than depresses the vaso-motor centres.*

On the heart itself chloroform undoubtedly exerts a steady, powerful depressing influence. Injected into the jugular vein,* it instantly arrests the heart's action and destroys its muscular irritability.† Even the vapor of chloroform, when locally applied to the exposed heart, paralyzes it (*Edinb. Med. Journ.*, 1842). When artificial respiration is maintained, the effect of chloroform upon the heart is very apparent (*Journ. Anat. and Physiol.*, xiii. 226). By a very ingenious series of experiments, Dr. MacWilliam (*Brit. Med. Journ.*, vol. ii., 1890) has proved that very early in chloroform anæsthesia there is a marked diminution of the force of the auricular and the ventricular beats, accompanied with dilatation of the cardiac chambers, due to the direct influence of the chloroform. Again, as stated by Gaskell and Shore, even the tracings of the Hyderabad Commission demonstrate that from the very beginning of chloroformization the excursions of the heart-beat, as shown on the Fick manometer in the most typical manner, get smaller and smaller as the pressure falls. Indeed, as Gaskell and Shore say, "every one would agree with the Commission that they [the pulse-waves] are of the typical kind which would be produced if direct weak-

* See also MacWilliam's experiments.

† Glover (*Edinb. Med. Journ.*, 1842), Gosselin (*Arch. Gén.*, 1845), Anstie, H. C. Wood.

ening of the heart were the cause of the fall of blood-pressure in chloroform administration."*

Putting all the evidence together, it seems to me to have been completely demonstrated by physiologists, first, that chloroform is a direct depressant and paralyzant to the heart-muscle or its contained ganglia;† second, that the fall of blood-pressure which occurs in chloroformization is in great part due to this direct depression of the heart.

Respiration.—So soon as psychical excitement has passed off, or, at first, if there be no such excitement, the respirations may be rendered slower by chloroform, but after a time they are generally quickened, and as the inhalation is persisted in they become more and more shallow, irregular and distant, and finally cease. In 1870 (*Journal of Anatomy*, May, 1870), Paul Bert asserted that during chloroformization there is more than the normal percentage of oxygen in the blood, but in 1885 he affirmed that there was less than the normal percentage (*Bull. Soc. Biolog.*, Juillet, 1885). There does not seem to be much doubt but that the results of L. G. de Saint-Martin (*La Respiration*, Paris, 1893) are correct.—namely, that whilst (probably on account of excessive respiration from excitement) in the beginning of chloroformization there is sometimes hyperoxygenation of the blood, the rule during full anaesthesia is decrease of the oxygen of the blood with increase of the carbonic acid.

Blood.—According to Harley (*Physiol. Trans.*, London, 1865), blood to which as little as five per cent. of chloroform has been added becomes very liquid and of a bright arterial hue. After a time crystals of oxyhæmoglobin form in it. Boettcher (*Virchow's Arch.*, vol. xxxii. p. 126) was,

* The work of the Hyderabad Commission has become so celebrated that it hardly seems necessary to explain that they reached with extreme positiveness the conclusion that chloroform kills purely through the respiration, and that it is a perfectly safe anæsthetic. Rather strangely, they based their belief that the fall of blood-pressure under chloroform is not due to weakening of the heart chiefly upon certain atypical tracings which they obtained. The publication of these tracings show, in the language of Gaskell and Shore, "that these cases afford no proof whatever that the heart's action is not impaired by the action of chloroform."

† REFLEX CARDIAC INHIBITION.—Intense irritation of the respiratory passages may have a very marked influence upon the heart by acting reflexly through the inhibitory centres, and some authorities believe that sudden arrest of the heart's action in this way occasionally occurs during chloroformization. Vulpian has shown (see CHLORAL) that a heart under the influence of chloral, a substance closely allied to chloroform in its heart action, is exceedingly sensitive to slight inhibitory impulses. It is notorious that during chloroformization death has often occurred immediately after the first incision. This suggests that the fatal syncope may be due to the irritation produced by the knife, and that it is wiser for the surgeon to wait until complete chloroformization occurs with absolute abolition of reflexes. I am myself, however, not inclined to attach much credence to the theory of reflex inhibitory arrest of the heart. In a careful series of experiments (see address on *Anæsthesia*), I found it easy in the dog to cause marked reflex inhibition of the heart by irritating the upper air-passages with chloroform, but it was impossible to produce complete cardiac arrest. The more rapidity of the occurrence of the syncope after the first whiff of the chloroform is of little importance as an argument in favor of the theory that death is caused by irritation of the peripheral nerves in the lungs, since the pulmonary absorption of chloroform is practically instantaneous and the blood goes directly from the lungs to the heart.

I believe, the first to study these changes closely. The first alteration noticeable in the red blood-disks is a diminution of their size, which A. Schmidt and F. Schweiger-Seidel (*Berichte d. königl. sachs. Gesellsch. d. Wissensch., math.-phys. Kl.*, 1867, p. 190) assert to be due to contraction, because when blood is treated with water until the red globules disappear, and carbonic acid gas is passed through the liquid until they reappear, on the addition of chloroform the sharply-contoured bodies will be seen to undergo marked contraction. As was first shown by Boettcher (*loc. cit.*, p. 127) and confirmed by Schmidt and Schweiger-Seidel, chloroform alone produces no other alteration than contraction in the red blood-disks. If, however, air be admitted to blood containing chloroform, the corpuscles rapidly disappear, dissolving in the serum, out of which, after a time, oxyhæmoglobin crystallizes. Both of the authorities quoted believe that the latter changes are due to oxidation. Boettcher states (*loc. cit.*, p. 129) that chloroform-vapor mixed with air converts enough of the oxygen of the latter into ozone to react with iodinated-starch paper; and Schmidt and Schweiger-Seidel have found that an excess of carbonic acid in the blood interferes with the changes caused by chloroform. From these facts it seems probable that their opinion as to the nature of the blood-changes is correct. Harley (*loc. cit.*) has studied the effect of chloroform on the absorption of gases in the blood. He states that when chloroform is added to fresh blood, and the mixture allowed to stand for twenty-four hours, a marked increase takes place in the proportion of oxygen and a lessening in that of carbonic acid. This is in accord with the theory just mentioned; for, after the complete oxidation of the hæmoglobin brought about by the chloroform, further consumption of oxygen could not occur, and, as it continued to be absorbed from the air, it must accumulate instead of being converted into carbonic acid.

How far, during ordinary narcosis, chloroform produces the changes just described in the blood is somewhat uncertain; but it would seem very improbable that they occur to any great extent. A very sensitive test of the destruction of the red disks in the body is found in the production of icterus; and icterus never follows anæsthesia. On the other hand, Husemann (*Schmidt's Jahrbücher*, Bd. cli. p. 84) intimates, on what authority I do not know, that after anæsthesia bile-acids (the precursors of icterus) appear in the urine. Nothnagel (*Berlin. Klin. Wochenschrift*, 1866) found in rabbits, after subcutaneous injections of chloroform or ether, bile coloring-matter in the urine; but Kappeler (*Die Anaesthetica*, Stuttgart, 1880), in twenty-five cases of chloroform-narcosis, was not able to obtain a trace of biliary coloring-matter (*Zeitschrift f. Physiolog. Chem.*, viii.). Dr. Sokolowski claims that the first few hours after chloroformization there is a decrease of the immature white blood-corpuscles, with an increase of the mature white blood-corpuscles, followed by gradual return to normal.

Action on Tissues.—The question of the general action of chloroform

upon the nutrition of the body is exceedingly important in relation to the various cases of death which have followed, some of them one, two, or perhaps three days after the chloroform-anæsthesia, and which seem to be unaccountable except by referring them to the anæsthesia. In 1890, OSTERLAG (*Deutsche Med. Zeit.*, Jan. 1890) reported an elaborate research made upon various species of the lower animals, in which it was found that the prolonged administration of chloroform was followed by a wide-spread fatty degeneration, affecting not only the glandular organs, but the skeletal muscles, especially of the diaphragm. There was at the same time alteration of the red blood-corpuscles. The fatty degeneration he believed to be due to direct action of the anæsthetic upon the tissues concerned. Dr. E. FRAENKEL (*Virchow's Archiv*, cxxix., 1892) has made pathological studies of four men dying a length of time after a prolonged chloroform-narcosis, and found a wide-spread necrotic degeneration of the parenchymatous cells in the kidneys, liver, and other organs, and also of the heart-muscles.

That chloroform affects the nutrition of the body is shown by the observation of STRASSMAN (*Virchow's Archiv*, 115), that marked increase of the nitrogenous elimination follows chloroform-narcosis, an increase which would seem to be directly due to the chloroform, since SALKOWSKI found that chloroform-water given to dogs distinctly increased the destruction of nitrogenous substances in the body without producing narcosis.*

Elimination.—Chloroform is undoubtedly, at least in part, eliminated as chloroform escaping with the breath, also with the urine. FUBINI (*Moleschott's Untersuchungen zur Naturlehre*, Bd. xiii., 1882) discovered it in the urine five hours after its inhalation. Dr. A. ZELLER believes that it is in part decomposed, because he has found the chlorides in the urine nearly doubled by its inhalation (*Zeitsch. f. Physiolog. Chemie*, Bd. viii. p. 74).

Albuminuria has been noticed both in animals and in man after chloroform-narcosis (*Gaz. Hebdom.*, Fév. 1884, 104; also *Brit. Med. Journ.*, 1883, ii. 623). It is affirmed, also, that astigmatism has been produced by chloroform inhalations (*Brit. Med. Journ.*, 1883, ii. 476).

In autopsies on persons who have died during chloroform-anæsthesia the presence of gas in the vessels and in the heart has been frequently noted. The sources of this gas have been much discussed, and various authors have arrived at the conclusion that the gas was the cause of the fatal issue. The subject has recently been elaborately studied by Dr. KAPPELER (*Archiv f. Klin. Chirurg.*, 1887, Bd. xxxi. p. 373), who appears to prove that in most cases the gas has been produced by putrefactive changes occurring after death. PIROGOFF, however, asserts that

* Dr. J. PETRUSCHKY (*Deutsche Med. Wochenschr.*, xvii., 1891) has noticed that after death from chloroform the intercellular juices become rapidly acid, and he has found that this is not peculiar to chloroform, but takes place also after death from ether, arsenic, and other poisons.

he has witnessed the throwing out of gas in the blood during life, but this observation stands alone. It is possible that the chloroform has some influence upon the capacity of the blood for holding gas. According to the researches of Strassmann (*Centralb. für Med. Wissensch.*, 1888), and of Salkowski (*Fortschr. d. Med.*, ix., 1891), chloroform is an active antiseptic and germicide. Both Salkowski and A. Bertels (*Virchow's Archiv*, cxxx., 1892) find that the drug also checks the action of pepsin and other unformed ferments.

THERAPEUTICS.—For a discussion of the use of chloroform as an anæsthetic, see page 154.

When administered by the mouth in sufficient quantity, chloroform produces symptoms similar to, but much more permanent than, those which it causes when inhaled. It is, however, very rarely, if ever, used in this way for its constitutional effect, but is sometimes of advantage in severe *neuralgia*. When quinine for any reason cannot be administered in an *ague*, a sufficient dose of chloroform (f3ss to f3i) to produce a mild narcosis, given just before the expected time for the recurrence of the chill, will usually abort it.

Chloroform by the mouth has been also highly recommended as a vermifuge in cases of *tape-worm*, but is of very doubtful value.

When chloroform is taken into the stomach, a considerable portion of it is, without doubt, evaporated, so that the intestinal canal becomes filled with the vapor. Chloroform, therefore, when so placed exerts both a local anodyne and a stimulant carminative action. For this reason it is extremely valuable in all cases of *colic*, and it will often even assuage the pain of *colica pictorum*.

Externally, as a rubefacient and anodyne, chloroform is very largely combined with other substances into liniments, which are especially useful in cases of *chronic neuralgia* or *rheumatic pains*.

Poisoning has been produced by the swallowing of chloroform. The symptoms induced have been stupor, with contracted, or, in later stages, dilated, pupils, and a stertorous respiration, which finally becomes very irregular, shallow, and often distant. The amount necessary to destroy life probably varies greatly, but, according to L. Lewin, a single drachm has produced death. In some cases (*N. Y. Med. Rec.*, July 11, 1885) the fatal result has occurred from secondary gastritis eight days after taking the medicine; and not rarely violent gastritis with jaundice apparently from inflammation of the gall-ducts has followed the taking of a poisonous dose of chloroform. Recovery has occurred after the ingestion of two ounces (Stillé, *Therapeutics*, vol. ii. p. 107), of one ounce (*Canada Lancet*, March, 1874), also of three ounces without vomiting (*Brit. Med. Journ.*, 1882, i. 776). The treatment consists in the use of the stomach-pump and of the various ordinary methods of arousing a narcotized patient, especially the alternate cold and hot douche, artificial respiration, and the very cautious use of diffusible stimuli if required. Death may occur during the narcosis,

or the patient may survive this and perish from inflammation of the trachea, œsophagus, and stomach, caused by the local action of the chloroform.

The recognition of chloroform as the probable cause of any given death cannot be based upon the post-mortem appearances. Indeed, the latter are of no value in deciding such a question. The anæsthetic may, however, be recovered by distillation of the lungs and blood within a certain period of time after death. As to the length of this time, so far as I am aware, no investigations have been made.

Criminal Relations.—Experiments made at the Philadelphia Hospital and confirmed by Professor Dolbeau (*Annales d'Hygiène*, Jan. 1874) have proved that persons sound asleep may be chloroformed without being awakened. Anæsthesia cannot, however, be produced in any one partially awake, or even sleeping lightly, without his or her knowledge.

Quite a number of professional men have been accused, and some convicted on the charge, of committing rape on females in whom they had induced anæsthesia. No doubt the women believed that they had been violated; but it is certain that in many of the cases, and probable that in all of them, they mistook for the real act the subjective erotic sensations induced by the chloroform or ether. The valuelessness of the testimony of persons as to occurrences during the time of their intoxication with anæsthetics should be recognized by law as a governing principle of evidence.

ADMINISTRATION.—Internally, from fifteen drops to a fluidrachm of chloroform may be given in emulsion, or, as it has recently been stated, dissolved in glycerin (1 to 3). The deep injection of half a drachm of chloroform has been recommended very strenuously by Professor Bartholow in obstinate neuralgia, and has found some favor in France (*Bull. Therap.*, xciii. 433, 471). In the only case in which I have tried it, one of trigeminal neuralgia, the local symptoms caused by it were so severe as to imperil the life of the patient. The U.S. Pharmacopœia recognizes a spirit (*Spiritus Chloroformi*—6 per cent., U.S.), dose, one to two fluidrachms, and an emulsion (*Emulsum Chloroformi*—4 per cent., U.S.); also a liniment (*Linimentum Chloroformi*—30 per cent., U.S.).

BROMIDE OF ETHYL is a colorless, very volatile, very fluid liquid, having the specific gravity 1.49, of a sweet, chloroform-like smell; not readily inflammable: insoluble in water, but mixing with ether, chloroform, fat, and ethereal oils in all proportions. It does not solidify at 32° F. Any preparation of it which has color, or seems irritating, or has a disagreeable smell, is unfit for medicinal use. It must clearly be separated by the practitioner from bromide of ethylene, which has a specific gravity 2.16, and solidifies at 32° into a crystalline mass. At least one, and probably more deaths have been produced by the substitution of the bromide of ethylene for the bromide of ethyl (see *Therap. Monatsh.*, 1889, vol. iii.). The bromide of ethyl degenerates under the

influence of light and air, and should, therefore, always be kept in small bottles of dark glass, closely corked. The impurity of the bromide of ethyl of commerce, and the difficulty of obtaining a pure drug, constitute an important objection to its common use.

The bromide of ethyl was first proposed as an anæsthetic by Dr. Thomas Nunnally in 1849, but was not brought earnestly before the profession until 1876-77, when attention was called to it by Rabuteau in France and Laurence Turnbull in the United States. Its influence is usually manifested a few seconds after the beginning of an inhalation and lasts from one and a half to three minutes after the removal of the drug from the mouth. A peculiarity that has been noted by several observers is a tendency for sensibility to be lost before consciousness has been completely destroyed, and Professor Montgomery has especially noted that during parturition the bromide of ethyl will do away with most of the suffering without arresting the pains or producing complete unconsciousness. The narcosis is only in rare instances accompanied by complete relaxation of the muscles; indeed, it appears to be common for the general muscular tonus to be greatly increased. According to Professor John H. Brinton, muscular excitement, as shown by rigidity, local spasms, and even general tetanus with opisthotonos, occurs so frequently as to seriously interfere with the anæsthetic use of the drug, especially as this condition during a surgical operation is attended with great increase of hemorrhage (*Therap. Gaz.*, viii.). During narcosis the corneal and pupillary reflexes are usually preserved, and the eyes are sometimes wide open and crossed from contractions of their muscles (Dr. Gilles, *Berlin. Klin. Wochens.*, xxix., 1892).

The physiological action of the bromide of ethyl has been partially studied by Schneider, by Abonyi, by Thornton and Maxwell (*Therap. Gaz.*, 1892), and by myself. Schneider states that the arterial pressure does not fall until very late in the bromide narcosis, and that death takes place always through arrest of the respiration. In these statements he is in accord with results obtained by Abonyi (*Wiener Klinik*, 1891. Heft 1), who was not able to detect any alteration in the beat of the exposed heart of the frog in which narcosis was produced. On the other hand, the experiments of Thornton and Maxwell are in agreement with my own in showing that fall of the arterial pressure occurs very early and increases steadily with a persistent inhalation. In my own experiments the bromide of ethyl seemed to act on the circulation precisely as does chloroform, although less powerfully. It is possible that this difference of result has depended upon some of the bromide of ethyl used being impure.

In the eighth edition of my "Treatise on Therapeutics" it was stated that clinical results show that the bromide of ethyl is a very dangerous anæsthetic, at the time of issue there having been three deaths reported as produced by it in a very limited number of administrations (*Therap. Monatsh.*, vol. ii., 1888, and Turnbull's *Anæsthesia*). To these

cases must be added the death recorded by Dr. A. Gleich (*Wien. Klin. Wochens.*, vol. v., 1892). On the other hand, Dr. Gilles claims (*Berlin. Klin. Wochens.*, vol. xxix., 1892) there were given in Germany during three years twenty thousand administrations without a single fatal result, and that there is no fatal result on record in which it has been proved that a chemically pure bromide has been administered. In Gleich's case, however, the bromide was that habitually used in the large German clinics, and it can scarcely be claimed that the bromide of ethyl is entirely free from danger. Our present knowledge appears to indicate that an absolutely pure bromide of ethyl is a proper substance for the production of brief anæsthesia, a substance whose extreme volatility lessens very greatly the danger of its use, because it escapes from the body almost as soon as the mask is removed from the face. The very brevity of its narcosis, and the muscular excitement apt to attend it, would seem to forbid the general use of the bromide as an anæsthetic, though it is well fitted for employment in minor operations.

The ease with which the bromide of ethyl undergoes change offers a serious difficulty to its use. Certainly the surgeon should see that the individual specimen employed has every appearance of being pure. Dr. Reich reports in the *Therap. Monatsh.*, 1893, a case in which the inhalation of a yellowish specimen of the bromide was followed by continuous vomiting and symptoms similar to those of acute phosphorus-poisoning, death occurring after seven days of excessive suffering. The liver and also the kidneys were found acutely degenerated. In using the bromide of ethyl the best way is to pour two to four drachms upon an Allis inhaler or the cone-shaped napkin.

PENTAL.—TRIMETHYLETHYLENE.—This is a colorless, highly inflammable liquid, boiling at 100.4° F., originally proposed by Dr. W. Lombardino as a practical anæsthetic. It acts with great promptness without marked disagreeable symptoms, producing a short narcosis, which is, however, longer than that caused by the bromide of ethyl. In three hundred narcoses by it, Dr. P. Philipp failed to find any depression of the heart or severe asphyxia (*Arch. f. Klin. Chir.*, xlv., 1892). The narcotic is also commended by Kleindienst, who, however, noted that very frequently three or four days after the narcosis there was abundant albuminuria, and not rarely hæmaturia or hæmoglobinuria occur. In a study of the drug given intravenously, and also by inhalation, by Dr. David Cerna (*Trans. Texas State Med. Assoc.*, 1893), anæsthesia with it in the dog was found to be accompanied always by marked fall of the arterial pressure, and the conclusion reached that the remedy depresses the heart. The alleged action of pental upon the kidneys, if it be true, negatives its use as a practical anæsthetic. From the statistics of Gurli (*Arch. f. Klin. Chir.*, xlv., 1893), it is the most dangerous of all the anæsthetics, there having been three deaths in the six hundred reported narcoses.

PRACTICAL ANÆSTHESIA.—Although various substances have from time to time been used as anæsthetics, the surgical profession has practically settled down to the employment of either ether or chloroform, and experience seems to show that there are no other known agents which act as well as do these two liquids. The question as to which of them should be preferred is a vital one, as are also the questions how to recognize and how to treat the accidents which occur during anæsthesia. It must be in the beginning granted that the production of anæsthesia is always attended with a danger which, though small, is positive, and that fatal accidents will always occur from time to time. All that a surgeon can hope for is to reduce the number of these accidents to a minimum.

In selecting the agent, convenience of administration both to the surgeon and to the patient is, of course, of importance; but I hold that such advantage ought not to be pitted against danger of fatal results. Without going into a detailed consideration of the statistics, it is sufficient for our purpose to accept the figures of the most recent and elaborate statement of the matter, that of Dr. Laurence Turnbull, who has collected three hundred and seventy-five deaths as reported from chloroform, and fifty-two from ether. For reasons which I gave in full in my address on anæsthesia before the Berlin International Congress, it seems to me almost certain that these deaths do not represent more than a third of those which have occurred. The ratio of deaths to inhalations for chloroform is given by Lyman as 1 in 5860; by Richardson as 1 in 2500 to 3000 (see also Coats, *Glasgow Med. Journ.*, xxxiv. 323); whilst Andrews put it for ether at 1 in 23,204, and Lyman at 1 in 16,542. In nearly one million of inhalations (Geo. M. Gould, *Medical News*, Oct. 1892) the mortality was, with chloroform, 1 in 3749; ether, 1 in 16,675. These later figures rest upon such a wide basis, and so concord with previous results, that it seems to me it must be considered established that the ratio of deaths from chloroform is about four times greater than that from ether.

The advantages of chloroform over ether are—that it is less disagreeable to the patient, produces less excitement, more speedily reduces the subject to insensibility, and is less apt to cause excessive after-nausea and vomiting. These advantages do not at all counterbalance the great danger to life, and I believe that the surgeon is not justified in using chloroform unless under certain circumstances, and for certain definite reasons.

Moreover, I believe that many of the so-called disadvantages of ether can be overcome by a little care. If the stomach be empty, the after-nausea will rarely be severe, and when the ether is properly given with an Allis inhaler, the average time required for the production of complete insensibility is eight minutes, and the sense of suffocation and the symptoms of excitement are rarely pronounced. These remarks naturally lead to a consideration of the best methods of producing anæsthesia.

Unlike the vapor of chloroform, the vapor of ether should be administered in a concentrated form. According to Dr. Snow, air at 80° F. saturated with ether contains seventy-one per cent. of the vapor. This point is probably never reached in the practical use of ether, but the more nearly it is approached the more rapid will be the induction of anæsthesia.*

The ordinary method of the administration of ether in Philadelphia is as follows:

Out of stiff paper a cone is made of such size and shape that its base will fit closely over the nose and mouth of the patient. In this cone a napkin, a small towel, or a conical, hollowed-out sponge is to be placed. About an ounce and a half of ether having been poured on the napkin, the cone is to be closely applied to the face of the patient, and kept there. When patients are fastidious and a few moments are of no importance, the gradual commencement of the inhalation is much more pleasant, as the first choking sensation is thereby to a great extent avoided. The Allis inhaler† gives, however, much better results in every way than can be obtained by the cone.

Various mechanical inventions have been made for the administration of chloroform; but these inhalers do not appear to offer any advantages over the simple napkin, and, at least in this country, are rarely, if ever, used. A handkerchief or towel may be folded into a bird's-nest shape, and twenty or thirty drops of the anæsthetic be put upon this and then held close to the mouth. Dr. Simpson advises that a towel be laid over the mouth and nose, and the chloroform slowly dropped upon this until anæsthesia is induced. Whatever plan be employed, it is of vital moment that the vapor be well diluted; not more than three and one-half per cent. of it should be contained in the inspired air.

The use of ether at night requires care. I have seen a flame, by lighting the vapor, pass through eight feet and set on fire the ether sponge and the patient. As the vapor of ether is heavier than air, if the anæsthetic be used at night the light should always be elevated. In the *London Practitioner* (vol. xlii.), Dr. D. R. Paterson details cases

* I have allowed this to stand as in former editions, but the researches of Dr. H. Dreser throw doubt upon the need of this great concentration. He found the air under the ether mask contained in some successful cases only 1.2-1.7 per cent. by volume; he further found that the percentage of carbonic acid was more, and of oxygen notably less, than the norm, showing that the respiratory activities were really increased, not decreased.

† The inhaler invented by Dr. O. H. Allis is based upon the theory that the patient to be etherized should be supplied with a full abundance of air, saturated with the vapor of ether. It consists essentially of a series of foldings of muslin on a wire framework, arranged almost like the gills of a fish, so as to allow the air to pass freely through, but everywhere to come in contact with ether. It should be placed upon the face of the patient dry, and the ether gradually poured on from a bottle with an especially prepared cork, known in Philadelphia as the "polyclinic" bottle. When properly used the Allis inhaler almost does away with the sense of suffocation and the consequent struggles which have made etherization alike so repulsive to patient and surgeon.

in which violent catarrhal inflammation of the respiratory passages has been produced by the use of chloroform in confined rooms with artificial light. The irritation he believes to be caused by phosgene gas formed by the decomposition of the chloroform (see also *Arch. f. Hygiene*, xiii., 1891). I cannot, however, conceive that any influence could be produced by phosgene gas during chloroformization, except in the small state-room of a ship or in a similarly confined apartment.

A study of the reasons of the great fatality of chloroformization leads to a study of the methods in which chloroform and ether produce death. My own teaching, in accordance with the general professional belief, has hitherto been: "First, that although ether in moderate doses acts as a stimulant to the circulation, yet, in overwhelming amount, it is capable of depressing the heart, but that such depression of the heart is always less than the depression of the respiration, and, therefore, ether kills always through the respiration; secondly, that chloroform may produce death by paralysis of the respiratory centre, or by a simultaneous arrest of respiration and circulation, but that primary paralysis of the heart may occur, and is especially prone to do so when the chloroform vapor has been given in concentrated form."

These teachings have been very strongly combated by the so-called Hyderabad Commission, led by Dr. Lauder Brunton, of London, who, as the result of four hundred and fifty experiments made upon the pariah dogs of India, came to the absolute conclusion that chloroform never kills by causing sudden stoppage of the heart. There is no space in the present volume to go over in detail the evidences which I brought forward in the address already spoken of. It was, however, I think, definitely proved that the clinical and experimental facts are accordant, and "that chloroform acts much more promptly and much more powerfully than does ether, both upon the respiratory centres and the heart; that the action of chloroform is much more persistent and permanent than is that of ether; that chloroform is capable of causing death either by primarily arresting the respiration, or by primarily stopping the heart, but that commonly both respiratory and cardiac functions are abolished at or about the same time; that ether usually acts very much more powerfully upon the respiration than upon the circulation, but that occasionally, and especially when the heart is feeble, ether is capable of acting as a cardiac paralyzant, and may produce death by cardiac arrest at a time when the respirations are fully maintained. These conclusions, which were based upon a thorough examination of clinical records and a very large number of experiments performed in the laboratory, have since been confirmed by Dr. John A. MacWilliam (*Brit. Med. Journ.*, vol. ii., 1890), who has recorded cases of death in the lower animals from chloroform, in which there was primary collapse of the heart; by the clinical studies of the Lancet Commission (*Lancet*, i., 1893), who found that out of 357 deaths caused by chloroform, whose

records they had examined, the fatal result was caused by cardiac failure 227 times, by respiratory failure 80 times, by simultaneous failure of the two functions 77 times.

MacWilliam also found that in the dog cardiac weakness and dilatation are always caused by chloroform, and in rare instances produced by ether. Both chloroform and ether are capable of causing arrest of the heart by a direct action upon the viscus, but chloroform is more apt to cause fatal accidents than ether, partly because its influence upon the heart is very much more decided, and partly because it persists much more tenaciously than does ether in its action upon the whole organization after its administration has been interrupted. It lets go its hold much less easily and much less rapidly than does ether.*

In practical anæsthesia it is a matter of the gravest importance to recognize the coming on of accidents. Cessation of respiration may be sudden; more usually it is gradual. Irregularities of respiration, and increasing shallowness of respiration appearing during the *advanced stages* of anæsthesia, are most urgent signals for the withdrawal of the anæsthetic and the use of prompt measures for relief. Failure of the pulse is, of course, of still more serious import, but it is often so sudden as not to be noticed immediately. It is always accompanied or immediately preceded by a peculiar change in the facial color or expression, and the anæsthetizer should therefore not merely watch the pulse, but especially the face. The measures which in the past have been especially relied upon in the treatment of chloroform anæsthesia are: dragging out of the tongue, inverting the patient, slapping with wet towels for the purpose of arousing reflex respiration, and the hypodermic use of ether, alcohol, ammonia, and certain other drugs.

Hypodermic injections of ether, though frequently employed, are so absolutely absurd that one wonders at the fatuity of surgeons. Ether in the blood acts as ether, whether it finds entrance through the lungs, through the rectum, or through the cellular tissue; and the man who would inject ether hypodermically into a patient who is dying from ether, should, to be logical, also saturate a sponge with the ether and crowd it upon his unfortunate victim.

The drug which has probably been most largely used is alcohol. The clinical and physiological relations of alcohol to ether and chloroform are, however, so close, that many years ago I became very doubtful of the value of this drug as a stimulant to a heart depressed by anæsthesia. These doubts continually grew stronger from what I saw and read as to the effects of the administration of alcohol during anæsthesia, and were finally changed into conviction by the experiments of R. Dubois (*Progrès Médical*, 1883, xi. 951), who found that in the animal to which alcohol has been freely given much less chloroform is required to kill than in the normal animal.

* If the observations of Julius Pohl (see page 144) be correct, the cause of this tenacity is storing of the chloroform in the nerve-centres, outside of the blood-vessels.

In a series of experiments made by injecting alcohol in various doses into the jugular vein of the dog whose heart was depressed with chloroform, I have found that the alcohol, if in sufficient dose to exert any perceptible influence, always increases the cardiac weakness, or, if in considerable dose, immediately paralyzes the viscus. I have no doubt that many persons have been killed by alcohol given to relieve cardiac failure during anaesthesia.

Experiments similar to those with alcohol just spoken of were made by myself:—with ammonia, which was found usually to have a distinct, though very fugacious, influence upon the chloroformed heart; with digitalis, which was found to have a very powerful stimulant influence upon the heart and blood-pressure; with nitrite of amyl, which failed to produce any pronounced influence for good; with caffeine, which seemed to have little or no power; with strychnine, which had some slight influence upon the blood-pressure, but an enormous one upon the respiration of the chloroformed animal. Thus, I have seen a respiration, which had practically ceased for ten seconds, suddenly, under the influence of an injection of strychnine, become very quick and full. Cocaine I did not try, but studies made with it since upon chloralized dogs indicate that it has distinct value, especially when given with the strychnine.

In the first edition of the present treatise I wrote: "Whenever there is any failure of the heart's action, as is nearly always the case, the body should be laid at an angle of 40° , with the head downward, so as to favor the passage of arterialized blood to the brain" (Dr. E. L. Holmes, *Chicago Medical Journal*, Sept. 1868). Some years after this the method was claimed as having originated with Nélaton. It undoubtedly has value. In a series of experiments I have found that the body of the animal whose circulation has been paralyzed by chloroform acts in a measure like a tube filled with liquid. When the feet are raised above the head there is a marked increase in the blood-pressure in the carotid, with decrease in the blood-pressure in the femorals; and when, on the other hand, the feet are dropped below the head, the blood-pressure falls in the carotid, but rises in the femorals. In none of my experiments was the respiration affected by the procedure, but in a number of cases the heart, which had entirely ceased, suddenly resumed its work when the feet were elevated, and the conclusion was reached that inversion causes the blood which has collected in the extremely relaxed abdominal vessels to flow into and distend the right side of the heart, and that this distention at times has a sufficient influence to stimulate into action a failing organ.

The one measure which I found in my experiments upon fatally anesthetized animals to surpass, in practical efficiency, all others combined, was artificial respiration, by means of which I frequently resuscitated animals in which all cardiac and respiratory movements had ceased.

In the light of all our present clinical and experimental knowledge,

the following rules may be formulated as embodying the treatment of the accidents of anæsthesia :

First. Unless the pulse be beating actively, partially invert the body of the patient.

Second. Place the index fingers of each hand upon the corresponding cornua of the hyoid bone, whilst the middle fingers rest upon the angle of the jaw, and then press forward and upward, the same force serving to extend the head upon the neck ; if this fail to open the glottis, by means of a tenaculum, thrust far back into the base of the tongue, draw it forward.*

Third. Make a momentary effort to stimulate respiration by slapping the chest, by douching with cold water, or by the method, suggested by Dr. Hare, of pouring a little ether on the bared abdomen, so as to get the effect of cold. Do not waste time if respiration has failed in any of these attempts.

Fourth. Avoid the use of all drugs except digitalis, strychnine, cocaine, ammonia, and possibly nitrite of amyl. Give digitalis, strychnine, and cocaine hypodermically or intravenously, as the most reliable of agents.

Fifth. Commence artificial respiration at once, even when the heart is primarily affected, as the great hope of the patient is the removal of the anæsthetic from the residual air of the lungs, so as to facilitate its escape from the blood.

It is evident that the ordinary methods of practising artificial respiration in men are exceedingly imperfect and feeble, and that in the accidents of anæsthesia so-called *forced artificial respiration* should be at once employed (see address on *Anæsthesia*). The principle of forced artificial respiration consists simply of pumping air into the lungs by means of a bellows. Fell's apparatus is efficient, but unnecessarily complicated ; a simpler one is described in a foot-note.† When no apparatus

* Dr. Benjamin Howard asserts that the common practice of drawing out the tongue has no influence in raising the paralyzed epiglottis, which he affirms can only be accomplished by extending the head and neck ; but in the elaborate experiments made in the University laboratories by Drs. Hubert A. Hare and Edward Martin it was demonstrated that the method of Dr. Howard is inferior to that given in the text (*Medical News*, 1889).

† APPARATUS FOR ARTIFICIAL RESPIRATION.—Dr. Fell's apparatus consists of a pair of foot bellows by which air is forced into a receiving chamber, which is connected with an apparatus for warming the air, and a valve which can be opened and shut by a movement of the finger. This valve, in turn, leads to the tracheal tube. When the valve is opened the air rushes through the chamber into the lungs and expands them ; the finger is lifted, the valve shuts, the lungs contract, and so the respiration goes on.

A much simpler, cheaper, and probably equally efficient apparatus may consist simply of a pair of bellows of proper size, a few feet of india-rubber tubing, a face mask, and two sizes of intubation tubes ; there should also be set in the tubing a double tube, with an opening similar to that commonly found in the tracheal canula of the physiological laboratory, so that the operator can allow the escape of any excess of air thrown by the bellows. In a recent article (*Journ. Amer. Assoc.*, xii., 1892) Dr. Fell insists on the superiority of his apparatus, and possibly in a large surgical clinic it might be well to provide his rather complicated mechanism.

is at hand, *forced insufflation* by breathing into the patient's mouth may be tried. Dr. A. E. Prince reports (*New York Med. Record*, 1892) a case saved in this way.

In using this apparatus, the mask should be first tried, care being exercised to see that the tongue is well drawn forward and held in place by a thread through it, and that the epiglottis is kept open. If the lungs do not fully expand, the intubation tube may be used. Whether the mask or the intubation tube be employed, the lungs should be thoroughly but slowly expanded by each stroke of the bellows, and a respiratory rate of about sixteen to twenty a minute be steadily maintained. It is essential to free the lungs and blood as rapidly as possible of chloroform, by quickly changing the residual air of the lungs; but of course due care must be exercised that no force sufficient to rupture air-vesicles be employed. When the symptoms are protracted, and the bodily temperature falls, the bodily heat must be maintained by external warmth, and the temperature of the room, unless the air entering the lungs be artificially heated, should not be less than 80° F.

BICHLORIDE OF METHYLENE was introduced to the notice of the profession by Dr. B. W. Richardson (*Med. Times and Gaz.*, 1867, p. 478) as an anæsthetic similar to, but more pleasant and possibly safer than, chloroform, and has been rather extensively used in London. It has never been largely employed in this country. There is no way of knowing how many times it has been administered, but nine cases of death from its use are recorded (*Brit. Med. Journ.*, 1883, ii. 104). The detailed phenomena in these cases indicate that, like chloroform, the bichloride of methylene kills by paralyzing the heart. It is not probable that it will ever come into general use as an anæsthetic.

BROMOFORM.—According to the researches of Bonome and Mazza, this substance acts as a general anæsthetic both upon man and upon the lower animals, causing, however, much irritation of the conjunctiva and the nasal mucous membrane. The narcotic stage is slowly developed and passes off slowly; the blood-pressure sinks somewhat; the respiration is not disturbed; the irritability of the brain-cortex is diminished. Bromoform is said also to be a powerful antizymotic (*Centralblatt f. Chirurgie*, 1884, 594. W. Gerhardt (*Inaug. Diss.*, Bonn, 1891) has shown that bromoform is capable of producing wide-spread fatty degeneration in the lower animals, and it is not probable that the drug will prove to be a practical anæsthetic. See also *Wien. Med. Jahrb.*, 1883, p. 497. For case of poisoning by mouth, see *Times and Register*, 1892.

FAMILY III—SOMNIFACIENTS.

In the family somnifacients are placed in this treatise those drugs whose chief use in practical medicine is for the production of sleep. The alkaloid hyoscyne is a hypnotic: it belongs, therefore, to the present family, and ought, theoretically speaking, to be considered in it. In nature hyoscyne, however, is closely associated with the mydriatic alkaloid hyoscyamine, which dominates all the crude preparations containing hyoscyne, and it is somewhat more convenient to discuss it along with that mydriatic alkaloid under the heading of *Hyoscyamus*, the crude drug from which both are derived.

OPIMUM. U.S.

The inspissated juice of the unripe capsules of the *Papaver somniferum*, or poppy. It is obtained by incising the capsules with a small, sharp knife, and twenty-four hours afterwards scraping off the exuded juice with a blunt blade. Opium is produced in various parts of the world,—chiefly in Turkey, Asia Minor, Persia, and India, but also to a very slight extent in England, Germany, and the United States. Our market is almost exclusively supplied from Asia Minor, with the variety known as *Smyrna* or *Turkey Opium*. This occurs in masses from the size of the fist to that of a child's head, irregularly globular, more or less flattened, covered externally with the capsules of a species of *Rumex* or dock, hard externally, softer and of a reddish-brown color within, and of a strong narcotic odor and taste.

Smyrna opium is at times variously adulterated with gum, liquorice, and other substances. Such specimens are said generally to want the *Rumex* capsules. A rough but pretty fair test of the purity of opium is performed by drawing a piece of it across a sheet of white paper. If it be much adulterated, the mark will be continuous,—not interrupted, as it should be. Often the black color, the adhesive consistency, and the sweetish taste will also betray the nature of the sample.

On exposure to the air, opium becomes hard and brittle, and is readily reduced to a powder of a yellowish-brown color. It yields to water, alcohol, and diluted acids, forming dark-brown solutions. Ether does not extract all of its medicinal principles. It is a very complex body, containing the alkaloids morphine, codeine, narceine, narcotine, thebaine, papaverine, porphyroxine, cryptopine, meconine, opianine, and

paramorphine, besides meconic, thebolactic, and sulphuric acids, extractive matter, gum, glucose, fixed oils, a volatile odorous principle, and other substances of no importance. In regard to the proportions of the more important principles, Messrs. Smith, of Edinburgh, obtained from 100 parts of fine opium 10 parts of morphine, 6 of narcotine, 1 of papaverine, 0.15 of thebaine, 0.03 of codeine, 0.01 of meconine, 0.02 of narceine, and 4 of meconic acid (*Pharm. Journ. and Trans.*, October, 1865, p. 183). Good opium should yield from nine to fourteen per cent of morphine.

As meconic acid strikes a blood-red color with a persalt of iron, the latter affords a ready, although not decisive, test for opium and the meconates.

PHYSIOLOGICAL ACTION.—When opium is taken in such dose as to produce its mildest physiological effects, it exerts a quieting influence, inducing a peculiar dreamy condition,—very generally a feeling of *bien-faisance*,—during which images and ideas float before the mind, and by their endless and effortless repetition shorten the time, which seems to lose itself in rest. It is commonly asserted that there is a stage of the action of opium in which the activity of the mental faculties is exalted. This may be so in some persons, and especially in those who have accustomed themselves to the use of the drug as a stimulant; but my experience is that in those who do not habitually take opium true mental power is, during all the stages of the action of the drug, diminished rather than increased. The state induced is rather the fabled calm of the lotus-eater than the energetic activity of production. Even in those who are accustomed to the use of opium as an aid to work, I think it is the imagination rather than the reasoning faculty that is excited by it. After a length of time, varying according to the idiosyncrasies of the patient and the dose of the drug, the condition which has been noted gradually passes into sleep,—either light and dreamful, or natural, or heavy and deepening into stupor, according to the amount of the drug ingested. On awakening, the patient may return at once to his normal condition, but very often he experiences a state of depression, as shown by languor, a little headache, nausea, or even vomiting, which may last for some hours.

After very large doses, the first stage of the action of opium is very short, or it may be entirely wanting, sleep coming on almost at once. Thus, I have seen deep coma produced in three minutes by a hypodermic injection of morphine. The symptoms of the second stage of opium-poisoning closely resemble those of congestion of the brain: the pupils are strongly contracted; the face is more or less suffused, often deeply cyanosed; the pulse full, slow and strong; the skin generally dry and warm; the respiration slow and deep, and, it may be, stertorous; unconsciousness is apparently complete, though generally the subject can be aroused by violent shaking or by shouting in his ear, but relapses at once when left to himself. When the patient is aroused, the

respirations become more rapid, and the skin often regains almost at once its normal color. Death very rarely occurs during this second stage of opium-poisoning. When the symptoms do not gradually ameliorate, the third stage, that of prostration, is developed. The coma is now profound, and to arouse the patient may be impossible; the pupils are absolutely contracted, or, as death approaches, are widely dilated; the respirations are distant, slow, feeble, and imperfect, and often interrupted by intervals of death-like quiet; the countenance is at once pallid and cyanosed; the pulse grows more and more rapid and more and more feeble; the skin is cold and moist, finally becoming covered with a clammy sweat. Even yet the patient may recover: if he do so, the return to life is very gradual; if he do not, death occurs generally by failure of the respiration, but amid an almost complete extinguishment of the vital functions.

Although the symptoms which have been narrated are those usually produced by opium, yet in certain individuals the drug provokes quite different phenomena. One of the most common of these departures from the ordinary course of symptoms is an excessive depression following the sleep produced by moderate doses of the medicine. This state is seen, so far as my experience goes, most usually in females of weak, nervous organization, such as are peculiarly liable to attacks of neuralgia. The symptoms are a feeling of weakness and prostration, often accompanied by chilliness, dull headache, and giddiness, but especially marked by intense nausea and frequent vomiting. Very frequently the latter does not occur so long as absolute rest in the horizontal position is maintained: indeed, an almost diagnostic sign of this affection may be found in the fact that the stomach is quiet so long as the patient keeps the head upon the pillow, but the distress occurs at once upon rising up. In some cases this condition of depression even replaces the normal second stage, so that opium, instead of inducing quiet sleep, will provoke alarming depression and vomiting, either with or without drowsiness. Thus, cases have been reported in which one-fourth of a grain, or a somewhat greater quantity, of morphine, hypodermically injected, has been followed at once by syncope, with struggling for breath, and apparently imminent or even present death.* A rarer idiosyncrasy exists in those persons who are rendered by opium very delirious, it may be even wildly so. In certain cases of opium-poisoning, partial or complete convulsions have occurred amidst the more usual phenomena. (Cases, *Brit. Med. Journ.*, 1876, ii. 496; *Pacific Med. and Surg. Journ.*, July, 1876.) Severe itching of the skin is a common phenomenon when the action of opium is going off, and there are persons in whom such violent erythema is produced even by

* See Report of the Committee on the Hypodermic Method of Injection, *Medico-Chirurgical Transactions*, vol. i.; see also *Medical Times and Gazette*, 1868, cases reported by Mr. Braine and by Mr. Roberts.

therapeutic doses as to forbid the use of the drug (case. *Wien. Med. Presse*, xxiv. 568; Dr. R. V. Jaksch (*Deutsche Med. Wochenschr.*, xiv. 1888) reports temporary blindness as produced by opium.

Opium at first sight appears to act so differently upon the lower animals from the way in which it acts upon man, that it seems necessary to discuss the former action by itself.

In 1526, Charvet (*Petrus's Materia Medica*, vol. ii p. 1035, Philadelphia, 1854) found that opium acts upon all classes of animals, inducing in the invertebrata weakness or paralysis of the contractile tissue, with gradual sinking and death: in fishes, a weakened paralytic condition of the muscular system, associated with convulsions; in birds and mammals, paralysis, convulsions, and stupor. These researches have been recently much extended, but in considering them I shall confine myself to the vertebrata.

When one or two grains of opium are injected under the skin of a frog (Kolliker, *Firchow's Archiv*, Bd. x. p. 248; J. F. H. Albers, *Firchow's Archiv*, Bd. xxvi. p. 229), in from six to ten minutes a condition of excitability is induced, so that the least touch produces violent tetanic convulsions, which, a little later, also occur without obvious cause. After a time, these convulsions gradually give way to a deepening paralysis. The breathing, previously disturbed, becomes more and more shallow and imperfect, and finally is suspended. Morphine acts, apparently, on frogs in the same manner as opium: at least Drs. Richard Gscheidlen (*Untersuchungen aus dem Physiolog. Laboratorium in Würzburg*, Bd. iii. p. 15) and W. Baxt (*Reichert's Archiv für Anatomie*, 1869, p. 128) have found that in large doses it induces the counter part of the series of phenomena just described. The latter observer noted, however, that when a minute dose (15.25 milligrammes) was employed, immediately following the injection came a brief period of disquietude; one minute afterwards the frog returned to its normal state, in from six to ten minutes suffered a diminution of excitability, and in from twelve to fifteen minutes fell into a stupor which continued from four to ten hours. After awakening, the reflex excitability seemed greater than normal.*

According to Kolliker, the opium-convulsions take place after the cord has been divided below the medulla, or even as low down as the third vertebra. In a single experiment, tetanus did not occur after division of the cord at the fifth vertebra; but the quietness was probably simply due to exhaustion, as the frog had already been poisoned for a length of time and had suffered section of the medulla and of the cord below the medulla. These facts seem to prove that the convulsions are reflex and of spinal origin. That the reflex centres of the cord are excited, Gscheidlen has confirmed by direct experiment, and

* Dr. S. Meibitsen affirms (*loc. cit.*) that this increased reflex activity is only towards chemical and not towards mechanical irritation. This is, however, opposed by such a mass of experimental evidence that I think it must be incorrect.

has also proved that in the latter stages, when the motor functions are depressed, the paralysis is largely of spinal origin, the reflex activity of the cord being greatly lessened. The convulsive movements which are present late in the poisoning would appear, however, to be of peripheral origin: at least, in Albers's experiments (*loc. cit.*) they occurred in limbs whose nerves had been previously cut so as to sever all connection with the nerve-centres. Further, both Kölliker and Albers assert that some of the convulsions are epileptiform,—i.e., of cerebral origin; and Dr. S. Meihuizen (*Arch. f. Physiolog.*, vii., 1873) states that the convulsions occur at a time when mechanical irritation fails to induce any response. If these experimental results be correct, opium apparently induces in the frog three kinds of convulsions, of which those of reflex origin are probably the chief.

Kölliker, from his investigations, concluded that opium does not act upon the peripheral nerves of frogs; but the recent very elaborate and apparently accurate experiments of R. Gscheidlen (*Untersuchungen aus dem Physiolog. Laboratorium in Würzburg, zweiter Theil*, 1869, p. 1) have shown that morphine in small doses increases the excitability of the motor nerves and afterwards depresses them; after large doses the period of excitation is short, that of depression soon coming on; and after enormous doses diminution of functional activity is at once manifested. Both Gscheidlen and Kölliker agree that neither the contractile power of the muscles nor the excitability of the motor nerves is destroyed by opium or morphine, although Albers (*Virchow's Archiv*, Bd. xxvi.) asserts that both are extinguished. Gscheidlen calls attention to this disagreement, and states that he has verified his own results by frequent experimentation with enormous doses of the alkaloid.

Experiments upon the sensory nerves are always unsatisfactory, but Gscheidlen (*loc. cit.*, p. 17), employing the method of Pflüger, found that morphine locally applied intensifies and protracts the excitability of an afferent nerve in cases of strychnic poisoning.*

Our knowledge of the action of morphine upon the nervous system of the frog may be summed up as follows:

Morphine in minute, non-toxic doses causes sleep, followed by augmentation of reflex activity; in large toxic doses it produces violent convulsions, followed by paralysis. The convulsions are chiefly spinal, and due to a heightened spinal activity, but are to some extent probably, also, of cerebral origin, and later in the attack arise from a direct action of the alkaloid upon the muscle or the nerve-endings therein; the paralysis is caused by a depression of the cord and a diminution of the conducting power in the nerves.

Dr. S. Weir Mitchell has shown (*American Journal of the Medical*

* Perhaps it is appropriate here to call attention to a paper by Dietl and Vintschgau (*Pflüger's Arch.*, Bd. xvi.), in which it is attempted to be experimentally shown that morphine increases, caffeine lessens, and alcohol first lessens and then increases the time required by the nervous system for the recognition of a peripheral irritation.

Sciences, Jan. 1869, and Jan. 1870) that birds, as represented by pigeons, chickens, and ducks, are very insusceptible to the toxic action of opium and its chief derivative, morphine. It appears to be impossible to kill a pigeon by opium given by the mouth, and of morphine from eight to fifteen grains are required to produce a fatal result; but when given hypodermically from two to three grains of the alkaloid suffice. These results have been in great measure confirmed by Dr. B. W. Richardson, and are no doubt accurate. The symptoms induced have been very uniform: they are unsteadiness, labored breathing, increasing signs of dyspnoea, unaltered pupils, and, finally, general convulsions and death. No true hypnotic effect has been observed, but a curious and very great rise of temperature just before death was noted in one case. As Flourens affirms that a single grain of the aqueous extract of opium will throw a sparrow into a profound stupor, it can scarcely be considered as proved that the drug acts upon all birds as upon those experimented with by Dr. Mitchell. According to M. L. Guinard (*Compt.-Rend.*, cxi., 1890), in the cat morphine produces violent hyperexcitability, great restlessness, agitation, hallucinations, dilated pupils, accelerated heart and respiration, from which the animal returns to its normal condition unless the dose have been very large, when tetanic convulsions develop.

Upon dogs morphine acts very much as upon man.* In very many cases, if not in the majority, eight to ten grains of the alkaloid injected into a dog of moderate size will cause deep sleep, amounting to coma, so that the animal will remain in any position in which he may be placed. The length and depth of this sleep are, of course, proportionate to the dose: when at all profound, it is accompanied by marked insensibility to pinching and other forms of external irritation. A repetition of irritation, and especially a sudden loud noise or shaking, will, however, arouse the animal, precisely as in man. Indeed, sometimes the dog, even when comatose, seems more than normally sensitive to sudden noise, trembling and starting in an almost convulsive manner. After awaking, the dog shows unmistakable signs of nervous and psychological depression. In walking, the hind legs are dragged, as though semi-paralyzed; the eyes are haggard; the naturally brave animal cowers in a corner or seeks to hide himself, no longer recognizing his master, and does not return to his natural condition for many hours. After smaller doses the effects are proportionately less intense. It has been shown by Harley that in some dogs, precisely as in some people, morphine fails to exert its usual hypnotic action, but produces great depression, as evinced by faintness, prolonged nausea, and retching, interrupted only by intervals of dreamy delirious somnolency.

* Harley, *The Old Vegetable Neurotics*, p. 107, London, 1869; Claude Bernard, *Archives G n rales*, ii. 437, 6th series, 1864; J. J. Reese, *American Journal of the Medical Sciences*, Jan. 1871.

In the horse (Harley, *loc. cit.*), two or even three grains of morphine hypodermically injected produces sometimes a slight drowsiness, sometimes no perceptible effect. Doses of from four to six grains cause great restlessness and accelerated pulse. The mouth is moist, the temperature of the skin and its secretion increased; the animal paws continually, and treads about in his stall with an almost rhythmical movement. After twelve grains, Harley noticed in some cases very great excitement, as shown by marked increase in the rapidity of the heart's action, by muscular rigidity and tremors, and by the animal's walking rapidly to and fro, slobbering and sweating profusely. In another horse, after an immediate strong erection of the penis and copious emission of semen, heavy sleep came on, interrupted after the third hour by the usual symptoms of excitement. Thirty-six grains of the acetate of morphine caused in a powerful hunter deep comatose sleep, commencing in fifteen minutes and lasting for three hours, when it was replaced by intense restlessness and severe delirium, continuing for seven hours. During this time the animal was perfectly blind.

Barbier's previous experiments upon the horse (quoted by Professor Stillé) yielded results similar to those of Harley. He used larger doses, and found that four drachms of the aqueous extract of opium produced violent tremblings, apparent insensibility to external irritants, convulsions without coma, and death. One hundred grains of the acetate of morphine killed a horse by convulsions in three hours.

In the mouse, according to the experiments of Harley, the first effect of an injection of from one-twentieth to one-twelfth of a grain of morphine is a tonic cramp-like contraction of the muscles, especially of the trunk, of such character that periods of forced rest alternate with a slow, laborious creep, which seems to originate not in the limbs but in the trunk itself. There is in this state no tendency to somnolency, but, on the contrary, an abnormal sensitiveness to loud sounds, which cause the mouse to resume for a moment active running movements. The breathing is irregular, the pulse accelerated, and finally stupor develops itself, and coma deepens into death by dyspnoea; or, otherwise, recovery, preceded by convulsive movements of the hinder part of the body, is gradually brought about.

In reviewing the action of morphine upon the lower animals, it becomes very evident that while we are not in a position to explain all the symptoms, yet two classes of phenomena are everywhere discernible,—i.e., the spinal and the cerebral,—and that the higher in the scale of life any given animal may be, the more marked are the brain-symptoms. These cerebral phenomena are mostly sleep and stupor; but, as is well known, in some human individuals morphine acts as a delirifacient; and it seems very probable that the peculiar restlessness of the horse under the influence of the alkaloid is due to delirium, and not to spinal excitement.

When looked at in this manner, it seems to me that morphine does

not act so differently as is generally believed upon the lower animals and upon man. The immensely higher cerebral organization of the latter, with the immensely greater sensitiveness which it involves, makes the man correspondingly more susceptible to the cerebral action of the drug: hence not only is he affected by much smaller doses of the alkaloid than are the lower animals, but as the spinal symptoms are triumphant in the frog because its spinal system is vastly more developed than its cerebral, so in man the cerebral symptoms mask the spinal because in him the brain is more developed than the cord. The two creatures—man and the frog—occupy the two extremes of the series; between them is probably to be found every gradation.*

The action of opium upon dogs and rabbits is sufficiently close to that upon man to enable us to reason from experiments upon the former as to the influence of the alkaloid upon the circulation and respiration in the latter. Indeed, so far as these functions are concerned, morphine appears to act identically in both instances.

Action on the Circulation.—In man, the circulatory phenomena are a slight primary evanescent acceleration of the pulse-rate (see Nothnagel, *Handbuch der Arzneimittellehre*, Berlin, 1870, p. 8), succeeded by slowing and increased fulness and force of the pulse, which is followed by a return to the normal pulse, or a great increase of rapidity and loss of strength, during the third stage. R. Gscheidlen has found in rabbits and dogs after the injection of morphine, first an increase in the pulse-rate, then a decrease, and finally return to the normal pulse, or else increased rapidity. Sphygmographic studies of the effects of small doses of morphine have been made with various results by several observers: undoubtedly in some individuals therapeutic amounts of the alkaloid depress sensibly the circulation, but, in agreement with Riegel and Priesendorffer (*Deutsches Archiv*, Bd. xxv. p. 48), it can scarcely be doubted that therapeutic doses have no sensible effect upon the circulation in the ordinary man.

The slow, full pulse of the second stage of opium-poisoning is due to an action of the drug upon the inhibitory cardiac nerves, as may also possibly be in some manner the increased arterial pressure; for Gscheidlen (*loc. cit.*, p. 45) has experimentally demonstrated that after section of the vagi morphine is powerless to lower the pulse, and also that division of the nerves during the second stage of morphine-poisoning is followed by an extraordinary rise in the pulse-rate. That the peripheral ends of the vagi are stimulated was proved by the fact that cardiac arrest took place when the distal ends of the cut nerve were more feebly irritated than would suffice to affect the unpoisoned animal; and that the inhibitory cerebral centres are stimulated was demon-

* A curious corroboration of the views expressed in this paragraph is found in the following sentence taken from Althaus (*Diseases of the Nervous System*, New York, 1878, p. 135): "In infants, however, and also in the lower races of mankind, as in negroes and Malays, convulsions are observed after its [opium] ingestion."

strated by the instantaneous very great fall of the pulse-rate, amounting in some cases to one-half in less than half a minute, which ensued upon the injection of a large dose of the alkaloid into the carotid,—i.e., into the brain and the inhibitory centres. The rapid feeble pulse of the third stage of opium-poisoning Gscheidlen found to be due, at least in a measure, to paralysis of the peripheral vagi; for at such time stimulation of the peripheral end of the cut nerve was powerless to affect the heart.

The experiments of Gscheidlen also indicate that morphine exerts *first a stimulating, then a depressing influence upon the heart-muscle or ganglia*, since, after isolation of the viscus by section of the cord, sympathetic, and pneumogastric, life being sustained by artificial respiration, a large dose of morphine induced a momentary increase in the number of the cardiac contractions, followed by a marked decrease and finally extinguishment of the same. This conclusion is confirmed by the experiments of Drs. Sydney Ringer and H. Sainsbury (*Brit. Med. Journ.*, March, 1883), who found that opium first increased the power of the cut-out heart of the frog, then depressed it, and finally caused diastolic arrest.

The question of the action of morphine upon the vaso-motor system is of great interest, but cannot at present be fully answered. Gscheidlen believes that it first stimulates and then depresses it, and asserts that after the injection of a large dose the arterioles in the mesentery can be seen to contract, and later (third stage) to dilate. The objections to this sort of evidence are sufficiently stated elsewhere in this book; and the rise of the arterial pressure, which he also adduces as an argument, may be accounted for without calling upon the aid of the vaso-motor nerves. While, therefore, it is probable that morphine does exert the influence he claims for it, the question must be still considered as *sub judice*: that the vaso-motor system is not paralyzed even in *extremis* is shown by Gscheidlen's experiment (*loc. cit.*, p. 52), in which electrical stimulation of the cord at such time induced immediate rise of the arterial pressure. The action of morphine upon the brain is certainly independent of any action on the vessels.*

Action on the Respiration.—Death occurs from opium, in the great majority of cases, by failure of the respiration; and that such failure is due to a direct action of the poison upon the respiratory centres in the medulla is proved by the fact that morphine affects the breathing of dogs and rabbits whose pneumogastrics have been cut, as much as it does those whose nerves are entire (Gscheidlen, *loc. cit.*, p. 64).

The action of opium or morphine upon the elimination of carbonic acid has been studied by Boeck and Bauer (*Zeitschr. f. Biolog.*, x. 339) and by Messrs. Chittenden and Cummins (*Laboratory of Physiological Chemistry, Yale University*, vol. ii.). Their results are concordant in

* Consult Binn, *Arch. f. Exper. Pathol. und Pharm.*, vi. 310; Vulpian, *Leçons sur l'Appar. vaso-moteur*, ii. 156.

showing that the effect of the alkaloid upon carbonic acid production is in direct relation to its influence upon the muscular system. The elimination is increased when convulsions occur, but decreased when narcotic quietude is produced.

Action on the Pupil.—Since morphine locally applied does not affect the pupil, it follows that its constitutional action upon the latter is through the nerve-centres. It is probable, but has not, that I am aware of, been experimentally proved, that the contraction of the pupil is due to a stimulation of the oculo-motor nerve-centres, and that the dilatation of the pupil as death approaches is due to a paralysis of the same. Indeed, it cannot well be otherwise; for if the primary contraction were due to paralysis of the sympathetic, the secondary wide dilatation would be impossible; the dilating force—i.e., the sympathetic—having been withdrawn, the pupil would not widely expand even if the contracting force—i.e., the oculo-motor—were paralyzed.

In birds (Dr. S. Weir Mitchell, *loc. cit.*) the pupil is not affected, probably for anatomical reasons (see *Atropine*). In horses it is widely dilated (Dr. Harley, *loc. cit.*); and in dogs it dilates before contracting (Dr. Reese, *loc. cit.*, apparently confirmed by Experiment number eight, Harley, *loc. cit.*, p. 109), or sometimes remains unchanged (Harley, *loc. cit.*, p. 111). At present these anomalies cannot be explained.

Elimination.—*Action on the Kidneys and Intestines.*—After its absorption morphine probably passes into all the secretions; after its hypodermic administration it has been detected in the gastric juice by Dr. K. Orlt (Berlin. *Klin. Wochens.*, 1889, xxvi.), and by Dr. Julius Rosenthal in the saliva (*Centralb. Klin. Med.*, 1893, i.); but it chiefly escapes with the urine, in which it has been found by Dr. Hilger (Gscheidlen, *loc. cit.*, p. 32), Bouchardat (*Schmidt's Jahrbücher*, Bd. cxx.), Lefort (*Journ. de Chimie*, Bd. xi.), Kausmann (*Inaug. Dissert.*, Dorpat, 1868), Kratter (*Virchow's Jahrb.*, 1882), W. Eliasson (*Inaug. Dissert.*, Königsberg, 1882), and Wormley (*University Med. Mag.*, 1890). Elimination probably goes on slowly, as Wormley detected the alkaloid in urine passed three days after its ingestion, and in habitual opium-eaters morphine occurs in the urine seven days after the cessation of the habit (*Lond. Med. Record*, 1887, p. 92). The theory that morphine is burnt up in the blood has been advocated by those who have failed to find it in the urine (see E. Landsberg, *Pflüger's Archiv*, 1880, p. 413; also Julius Donath, *Ibid.*, 1886, p. 528) and there is reason for believing that it and other alkaloids are to some extent destroyed in the liver. Moreover, A. Lamal claims that he has recovered from the blood and urine a morphine oxidation-product, *oxymorphine* (*Bull. de l'Acad. de Belg.*, 1888).

The amount of the urinary secretion is said to be sometimes increased by morphine; but generally it is diminished. Retention, which after a full dose of opium is not rare, depends upon the blunting of the sensibility of the bladder. In a series of examinations S. Fubini found that morphine, codeine, narceine, narcotine, and thebaine each increase the

excretion of urea in man: upon the lower animals their action seemed to vary greatly (*Hoffmann und Schwalbe Jahrb.* Bd. x., 1882, p. 218).

Peristaltic movements, according to the experiments of Professor Nothnagel (*Archiv f. Path. Anat.*, lxxxix. 2), confirmed by J. Ott (*N. Y. Med. Journ.*, 1883), are diminished by small doses of morphine but increased by toxic doses. The first effect is evidently due to stimulation of the inhibitory nervous apparatus, and the second to paralysis of the same: it is probable that it is the centre that is affected. The experiment which Professor Nothnagel brings forward as evincing a peripheral action is certainly not pertinent.

Upon the digestive tract opium exerts a very marked influence, checking secretion and causing constipation, acting in these respects more efficiently than does morphine.*

THERAPEUTICS.—The chief indications for the use of opium are considered below, *seriatim*. Nearly all of them flow evidently from the known physiological action of the drug; others, however, although established by clinical experience, and undeniable, are not so plain in their philosophy.

1. *To relieve pain.* As an analgesic, opium is without a rival in the *matéria medica*, except it be the anæsthetics. It is used to allay pain arising from any cause whatever, except acute inflammation of the brain, and is preferred to the anæsthetics whenever the pain has any permanency. In *painful spasm* it is especially useful, as it seems very frequently to quiet the motor as well as the sensory disturbance.

2. *To produce sleep.* Sleeplessness occurring in acute disease, and not dependent upon cerebral inflammation, may very frequently be relieved by opium. While it is often necessary to use the drug freely in such affections as *delirium tremens*, care should be exercised not to overwhelm the nerve-centres by enormous doses. In habitual sleeplessness great caution must be used in the employment of opium, not so much on account of the disturbance of digestion which it is liable to cause, as for fear of producing the "opium habit." Chloral is perhaps a more generally applicable hypnotic than opium. Be this, however, as it may, I have found the combination of morphine and chloral singularly efficient. In low fevers, adynamic delirium often coexists with sleeplessness, and is then best met by opium.

3. *To allay irritation.* In various forms of nervous erethism, opium

* The exercise of function is, no doubt, always dependent upon or connected with nutritive movements in the part. Without question, any poison which produces functional excitement affects the nutrition of the excited part. But this alteration of nutrition must rarely progress far enough to be recognizable by the microscope. Various pathologists have studied the condition of the spinal cord and other nerve-centres after poisoning by different toxic agents, and some believe that even after the use of morphine, bromide of potassium, and similar substances, distinct changes in the ganglionic nerve-cells are to be made out, while others have failed to detect these changes. For recent papers on the subject consult W. V. Tschisch (*Virchow's Archiv*, 1883, Bd. c. 147, and Dr. F. Kreyssig (*Virchow's Archiv*, 1884, Bd. cii. 287).

is most valuable; but when the affection is at all chronic, the dangers of the opium habit should not be lost sight of. On the other hand, in acute cases, as in the excitement which so frequently attends *hæmoptysis*, the drug should be used freely. In many cases of disease, opium is serviceable by sustaining the system against an irritation for the time being irremediable, by blunting the sensibilities. In this way it is useful in the advanced stages of *smallpox*, and in various surgical affections, in which it also does good by allaying pain. In various local irritations opium is continually employed, as in *colic* caused by undigested food, and in *bronchitis* to quiet cough.

By allaying irritation and pain, opium affords relief in most cases of inflammation; but in certain varieties of the affection it seems to do much more than this, exerting, in some way at present difficult to explain, a life-saving influence. In *peritonitis*, after due depletion, or in cases not requiring depletion, it should always be exhibited in large doses at regular intervals, in such a way as to keep the patient in a state of decided narcotism.

In severe *acute vomiting*, opium is one of the most reliable remedies. It is best used in the form of suppositories. Although, by checking secretion and peristalsis, opium usually causes constipation, yet when *obstruction of the bowels* is produced by spasm due to an irritation or inflammation, by relieving the latter the drug will sometimes act as a most efficient laxative.

4. *To check excessive secretion.* For this purpose opium is very largely employed in *diarrhæas*, and is very efficient either alone or in combination with various remedies. In *enteritis* and in *dysentery*, although no less frequently used than in *diarrhœa*, it is of service rather as an antiphlogistic and analgesic than by checking secretion. In *diabetes insipidus*, the combination of it and gallic acid has been much used, and is often effective.

In true *saccharine diabetes*, opium is of very great value in many cases, often ameliorating the symptoms, and, in conjunction with restricted diet, sometimes even effecting a cure. Of course, however, like all other known remedies in this disease, it most frequently acts simply as a palliative. According to Dr. Pavey (*Med. Times and Gaz.*, June, 1869), it affects the quantity of the urine before diminishing the sugar in it.

In severe *mercurial ptyalism*, opium often seems to check the discharge, but certainly is not nearly so powerful in this regard as is *belladonna* or *atropine*.

5. *To support the system.* Opium appears in low fevers, and in various protracted adynamic illnesses, to afford actual support to the system in some way not as yet made out. This is especially the case when, from any reason, sufficient food to keep up life cannot be taken or retained. Opium is a valuable remedy for the purpose of protracting and rendering more comfortable life in the aged. When the bodily

Powers are failing, and various functional disorders are from time to time occurring, it is often possible to check, by the use of opium, attacks which, if allowed to obtain headway, would extinguish the flickering life. Further in many cases of feeble very old and suffering people the habitual use of opium under careful restriction by the physician is not only justifiable, but necessary if life is to be maintained as long as possible. In such persons the danger of forming an opium habit which shall do injury is a minimum.

6. *As a sudorific.* Dr. A. Loomis (*N. Y. Med. Record*, 1873) praises very highly the use of hypodermic injections of morphine in acute uræmia. He states that the drug must be given in sufficient quantity to control the convulsions, which it does most happily, at the same time producing profuse diuresis. Dr. Morrison Fiset (*N. Y. Med. Record*, July, 1874) and Dr. Dain (*American Med. Journ.*, July, 1874) confirm this. In some instances the remedy has seemed to act very happily, but in one or two cases at the Philadelphia Hospital its exhibition was shortly followed by death, and I think the practice is a dangerous one. My own belief is that whenever the kidneys are seriously diseased the physician should be exceedingly careful in the administration of opiates, because the chief channel through which these are eliminated is choked up. In the form of Dover's powder, opium is very largely used when it is desired to produce sweating, as in the early stages of a "general cold," or in other forms of muscular rheumatism. With its use should generally be conjoined such measures as "soaking the feet," covering warm in bed, and the free drinking of hot lemonade or hot teas.

TOXICOLOGY.—Sufficient has already been said concerning the course and symptoms of poisoning by opium in ordinary cases.* Sometimes in adults trismus and other convulsive manifestations are added to, or in a measure replace, the usual phenomena, and in children the drug appears at times to overpower the nerve-centres at once, so that the second stage is very much shortened or aborted, and symptoms of collapse, with unconsciousness, are developed very rapidly. The positive diagnosis of opium-poisoning from the symptoms alone is often impossible.† In some cases of congestion of the brain, or of apoplexy, or of uræmia, the phenomena are identical with those sometimes seen in opium-poisoning. I have thought that inequality of the pupils is proof that a case is not one of narcotism; but Professor Taylor has recorded an instance of opium-poisoning in which it occurred (*Medical Jurisprudence*, 7th Am. ed., 1873, p. 205).

The indications in the treatment of poisoning by opium are: first, to evacuate the stomach; second, to maintain respiration; third, to keep up the circulation when failing. The first indication may be met

* For discussion of effect on nursing and fetus when morphine is given to the mother see *Amer. Journ. Obst.*, 1877.

† See *Philadelphia Med. Times*, ill. 593; also Dr. Wilks, *Med. Times and Gas.*, 1863.

in two different ways: by an emetic, and by the stomach-pump or tube used as a siphon. There is often in narcotic poisoning great difficulty in getting an emetic to act, owing to the obtunding of the sensibility of the nervous system by the drug. For this and other reasons, so palpable as not to need mentioning, a prompt stimulant emetic should be used. Antimony, on account of its depressing influence, should always be avoided. *Mustard flour* is almost always to be had at once, and is very efficient. A heaped tablespoonful stirred up in a tumblerful of warm water should be exhibited as soon as possible, and, if it fails to act in fifteen minutes, should be repeated; then a powder of thirty grains each of sulphate of zinc and ipecacuanha may be given, to be repeated once or twice, at intervals of fifteen or twenty minutes. Large draughts of warm water should be administered in the intervals, and also between the acts of vomiting, so as thoroughly to wash out the stomach. The stomach-pump* is of no value when the solid drug has been ingested, but, if at hand, is preferable to emetics when a fluid preparation has been taken, because of the promptness of its results.

To maintain respiration is the ultimate object of all the measures which are commonly undertaken for the purpose of arousing the system in opium-poisoning. Unconsciousness in itself is of no moment, but as it deepens the sensibility of the respiratory centres grows less, and consequently the involuntary breathing is less rapidly or less perfectly performed. More than this, when at all awake, a patient suffering from opium-poisoning can be made to supplement the almost suspended automatic breathing by voluntary respiration; and every effort to induce him to do this should be used. It is often surprising how an apparently unconscious man can be made to breathe by a command shouted in his ear. To keep a patient awake, walking, flagellations with small, *fine* twigs, shaking, shouting, and various other methods which may suggest themselves, should be practised. Care should always be exercised not to carry these useful measures unnecessarily far, and perhaps add physical exhaustion to the natural prostration of the third stage. I desire also to call especial attention to strong faradic currents as a means of causing pain, and therefore of rousing the patient, without leaving the bruises and soreness which often result from the severe flagellations practised.

The cold douche affords an excellent method of rousing the patient and at the same time of especially stimulating respiration. The simplest method of application is to support the head and shoulders of a patient stripped to the waist over a common wash-tub, and to dash the water over the chest and head. The effect is much greater if ice-cold

* The siphon stomach-pump may be extemporised by any one. It consist simply of an india-rubber tube three and a half to four and a half feet in length, of proper calibre, which is passed into the stomach. The external end being elevated, water is poured into it until the stomach is full; then, without the tube being allowed to empty itself, the external end is dropped, when, of course, the flow of water is reversed.

water and water a little hotter than the hand will bear (115° F.) be used in quick succession. In the way of drugs, there are only three substances worthy of mention. Very strong infusions of coffee or of green tea have been long used in opium-poisoning, and recent scientific studies (*Brit. Med. Journ.*, 1874, ii. 698, 699) have shown that in animals doses of morphine otherwise lethal may be successfully combated by theine or caffeine; atropine, as a respiratory stimulant, is of the greatest value in opium-poisoning when there is evident failure of respiration (for discussion of its use, see the article on Atropine); and alcohol is to be employed in the stage of depression to sustain the arterial system.* I have found, in the laboratory, strychnine to act very powerfully as a respiratory stimulant in narcotized animals, and Dr. Clara Dercum (*University Med. Mag.*, 1870) reports a case in which life was apparently saved by use of the alkaloid. It is essential that the alkaloid be given in very large dose. In bad cases of opium-poisoning the use of artificial respiration should not be too long postponed. In some cases the Sylvester method may suffice, but, as was first shown by Dr. Geo. E. Fell (*New York Med. State Assoc.*, 1888-89), forced respiration (see page 159) should be resorted to whenever respiration fails. Dr. Fell has reported recovery obtained in this way after the ingestion of twenty grains of morphine. So long as any movement of the heart continues, the forced respiration should be steadily maintained. In some cases the lungs become filled up with bronchial mucus. Under such circumstances good may be achieved by placing the patient in an inverted position (*Brit. Med. Journ.*, 1871, vol. ii.). It is often essential to keep up the temperature of the body by artificial means. Drs. Lauder Brunton and Cash have found that the fall of temperature in the poisoned mammal is not prevented by placing the animal in a temperature a little below that of the body; and the ordinary methods used in the sick room to heat the cooling human body are of very little service. The hot bath or a water bed, two-thirds filled with water of the temperature of 150°, may be employed.

Opium-poisoning usually has no sequelæ; but a case in which *amaurosis* was produced is reported in *Schmidt's Jahrbucher*, Bd. clvii. p. 74, and *glycosuria* is said to have followed the poisoning (*La France Med.*, 1883, ii.).

In regard to the amount of opium which will cause death, the smallest fatal dose on record is one-sixth of a grain of morphine in the adult (Dr. Buskirk, *Washington Post*, Jan. 30, 1878).† According

* Various drugs have been stated to be antagonistic to opium and cases of recovery reported. VERATRIN VERIBL, *Cincinnati Lancet and Clinic*, 1872, iii. 458; *St. Louis Med. and Surg. Journ.*, 1870, xxxvii. 601; ACONITE, *New York Med. Record*, 1880, viii.

† A number of cases are now on record in which death has been produced in the adult by the hypodermic use of from one-sixth to one-half grain of morphine. *Consult Med. Chir.*, 1884, vol. 1, *Chicago Med. Examiner*, May, 1878, *Quart. Journ. Psycholog. Med.*, 1868, 79.

to Dr. A. Calkins (*Quart. Journ. Psycholog. Med.*, 1868, ii. 739), four grains* of crude opium placed in the ear have caused death; also four grains by the mouth in more than one case. According to the authority just quoted, out of twenty-nine reported cases in which a fluid-ounce of laudanum was taken, nine died. The maximum doses from which recovery has occurred without emesis are fifty-five grains of the solid opium and six ounces of laudanum. In a babe a day old, one minim of laudanum (E. Smith, *Lancet*, 1854), and in one aged nine months, a few drops of paregoric (Wood, *Bost. Med. Surg. Journ.*, 1858), have proved fatal. Death of an adult female has been attributed, with doubtful accuracy, to thirty grains of Dover's powder, given in divided doses (*Chicago Med. Journ. and Exam.*, July, 1882), and still more hypothetically to a quarter of a grain of morphine (*Boston Med. Surg. Journ.*, Jan. 3, 1885). Recovery is asserted to have occurred after the ingestion of eight teen grains of morphine without vomiting (Dr. Wm. C. Chaffee, *Med. Surg. Rep.*, 1882, xlvii. 697).

For full details as to the results of the habitual use of opium or its alkaloid, the reader is referred to the treatise of Dr. Albrecht Erlensmeyer (*Die Morphiumsucht*). No confidence can be placed in the statements of the opium-eater, and it is essential for cure that such person be in a hospital or be confined to an apartment under the care of an absolutely reliable nurse, so that the orders of the physician can be strictly enforced. The basis of the treatment must consist in the withdrawal of the narcotic, and there are three distinct ways in which this can be effected. First, the opium may be suddenly taken away; secondly, it may be taken away rapidly, but not suddenly; thirdly, it may be withdrawn very gradually. The first of these methods is undoubtedly in most cases efficient, but is often attended with grave danger of collapse, and has no distinct advantages over the plan of rapid withdrawal. The time required for the very gradual withdrawal of the remedy is too great for practical purposes, and the sufferings of the patient are too long drawn out. Unless the daily dose has been extraordinary or the patient is in a very feeble condition, it is entirely safe to withdraw the narcotic entirely in from seven to twelve days. An excellent plan is to direct that a solution of morphine or opium be prepared, and whenever a dose is taken out an equivalent amount of water be added. The chief symptoms that follow the rapid withdrawal are excessive malaise, insomnia, complete loss of appetite, vomiting, diarrhœa, and great feebleness. I have never yet seen a case in which those symptoms were so uncontrollable as really to cause alarm for the safety of the patient. Much may be done by proper feeding. The food should consist of highly nutritious, stimulating, and easily-digested articles, and in severe cases should be liquid, such as milk, rich soups, etc. When the circulation fails, alcohol may be used, and much relief

* Taken from *Journal de Chimie*, 1831. Assuredly there is a mistake in this case.

may be afforded by massage, and often by simple rubbing of the patient. General electrical stimulation and faradization of the muscles is often useful, not only by its effect upon the circulation, but also by distracting the attention of the patient from his sufferings. The use of the alkaloid cocaine as a stimulant has been recommended. I have seen apparently very good results from the free internal administration of the fluid extract of coca, but I do not think that the use of hypodermic injections of cocaine is justifiable, as the danger of setting up the cocaine habit is too great. If gastro-intestinal irritation exists, bismuth may be administered freely. The diarrhoea is usually controllable by mild astringents, especially if combined with sulphuric acid. If the bodily temperature falls at all, it must be maintained by external warmth. The bromide of potassium, valerianate of ammonium, Hoffman's anodyne, and other similar feeble nerve-sedatives may be employed and give some comfort. Moral support and stimulation are essential, and any device which aids in passing the time of suffering is most beneficial.

ADMINISTRATION.—When it is desired to produce very decided narcotism by the use of repeated doses of opium, the drug should always be given in liquid form, since opium pills sometimes become very hard and undergo solution so slowly that they may accumulate in the alimentary canal. On the other hand, in diarrhoeas, or in sickness of the stomach, old opium pills are thought by some to act better than do more soluble forms of the drug.

Many persons cannot take opium on account of the very great secondary nausea and depression which it produces. It has been supposed that these disagreeable after-effects are due to the narcotine in opium; but this can hardly be, seeing that they often follow the use of the pure alkaloid, morphine. The deodorized tincture of opium agrees with some individuals better than any other preparation of the drug, and, as first pointed out by Dr. Da Costa, by giving a drachm of the bromide of potassium with twenty-five drops of it, the after-effects of the narcotic are often entirely avoided. In many neuralgic women the knowledge of this fact is an inestimable boon; in others the unpleasant symptoms are not averted by the bromide.

Children always bear opium very badly, and to them only the weaker liquid preparations should be given. Dover's powder should especially be avoided. It is probable that in its manufacture on the large scale the ingredients are sometimes not thoroughly mixed: at least I have seen cases in which the symptoms caused by it were seemingly so out of proportion to the dose as to suggest that more than the official amount of opium was present.

In acute vomiting from any cause, in dysentery, in strangury and other irritations of the urino-genital organs, great advantage is often to be gained from the use of opium by the rectum. Suppositories made out of the extract (gr. ss to i), or enemata of laudanum (gtt. xxx

to xl), may be used in these cases. The latter should be made by adding the narcotic to a tablespoonful of starch-water.

The dose of opium for an adult is from one to two grains; for a child a year old, one-twenty-fourth of a grain. The U.S. Pharmacopœia directs that opium in its normal moist condition should contain not less than nine per cent. of morphine, and that dried *powdered opium* (*Opii Pulvis*, U.S.), out of which the preparations are made, should contain from thirteen to fifteen per cent. of the alkaloid.

The solid officinal preparations of opium are—the *deodorized opium* (*Opium Deodoratum*, U.S., *Opium Denarcotizatum*, U.S. 1880), containing from thirteen to fifteen per cent. of opium, made by depriving powdered opium of all substances soluble in ether, dose, one to two grains; *pills of opium* (*Pilulæ Opii*, U.S.), containing one grain each of powdered opium; *watery extract* (*Extractum Opii*, U.S.), containing eighteen per cent. of morphine, three-quarters of a grain are about equal to one grain of powdered or deodorized opium, and on account of its being the most fixed in its strength of any of the solid preparations of opium, as well as of its being free from the noxious constituents of opium, and of its solubility favoring prompt absorption, it is the most useful and reliable of all the solid preparations of the drug; *Dover's powder* (*Pulvis Ipecacuanhæ et Opii*, U.S.), one grain of opium, one grain of ipecacuanha, eight grains of sugar of milk.

Paregoric (*Tinctura Opii Camphorata*, U.S.) has in every fluidounce 1.85 grains of opium, besides benzoic acid, oil of anise, and camphor, and, in consequence of the last ingredient, is more constipating than the other preparations of opium, and hence is preferred in diarrhœa-mixtures. It is also much used in cough-mixtures. Dose, ℥i to ℥i. The other liquid preparations all *now* represent ten per cent. of *powdered opium* by weight, and may be given in doses of ten to fifteen minims. The *deodorized tincture* (*Tinctura Opii Deodorati*, U.S.) contains no narcotina, and none of the odorous principle of opium. It therefore is less apt to cause nausea than are the other preparations. Its drop almost equals the minim in size. The other preparations are—*Tinctura Opii*, U.S., or *Laudanum* (one hundred drops to the fluidrachm); *Vinum Opii*, U.S., or *Sydenham's Laudanum* (formerly ℥i to ℥i); *Acetum Opii*, U.S., or *Black Drop* (formerly gr. lxxv to ℥i).

MORPHINA.* U.S.

This alkaloid occurs in minute, colorless, shining crystals, according to Guy melting at 330° F. and subliming at 340° F.; insoluble in cold and nearly so in boiling water; only slightly soluble in cold alcohol and ether; freely soluble in boiling alcohol and in the fixed and volatile oils.

* For a very interesting paper upon the derivatives of morphine and their physiological effects, by Drs. D. B. Dott and Ralph Stockman, see *Proceed. Royal Soc., Edinb.*, 1890.

The following are some of the most sensitive and characteristic tests. In a solution of the alkaloid in concentrated sulphuric acid, which has been allowed to stand from ten to twelve hours, or has been heated for half an hour to 100° C. or momentarily to 150° C. and allowed to cool, the faint-reddish violet changes at the point of contact to a deep-blue violet upon the addition of dilute nitric acid or of a crystal of saltpetre. Morphine with concentrated sulphuric acid makes a colorless solution, which on strong heating becomes red, violet, dirty green. With concentrated nitric acid it makes a red color, and finally a yellowish solution. With the neutral chloride of iron morphine strikes a blue color, perceptible only when the test contains one part of the alkaloid in six hundred. Less characteristic, but much more sensitive, is the iodine test, with which, according to Husemann, one-ten-thousandth part of morphine can be recognized. Iodic acid, in the form of a mixture of iodate of potassium and sulphuric acid, is to be added to the suspected solution. If morphine be present, iodine will be set free, and can be recognized by the starch test.

The *Morphine Acetate* (*Morphine Acetas*), *Sulphate* (*Morphinæ Sulphas*), and *Hydrochlorate* (*Muriate of Morphine*, *Morphinæ Hydrochloras*) are all official. The first is a white powder; the last two occur snow-white in feathery crystals. They are all soluble in water, are of a bitter taste, and physiologically and therapeutically of the same value.

THERAPEUTICS.—The salts of morphine differ in their therapeutic value from opium chiefly in that they act with less power as sudorifics and in checking secretion in the bowels, and consequently are less constipating. The smallness of their dose and their perfect solubility fit them for hypodermic use. Almost the only purpose for which they are used in this way is to relieve pain. The advantages of the method are the quickness of the results and the increased power of relieving suffering which the remedy seems to acquire. In cases of severe pain, hypodermics are invaluable; but it must be borne in mind that sometimes they cause most unpleasant symptoms. I have seen very alarming results from the injection of one-sixth of a grain, and half a grain has produced death. In females, unless very robust, the maximum dose should be one-eighth of a grain; in men, one-sixth to one-quarter. The dose of a salt of morphine corresponding to a grain of opium is one-quarter of a grain. The dose of the formerly officinal solution (*Liquor Morphinæ Sulphatis*, U.S. 1870,—gr. i to fʒi) is one to three drachms. *Magendie's Solution of Morphine* contains sixteen grains to the fluid-ounce; it is not official, and should not be kept by the apothecary.

NARCEINA.

This alkaloid, which is not officinal, was discovered by Pelletier in 1832. "It crystallizes out of its watery, alcoholic, and dilute acid solutions in long, white, four-sided, rhombic prisms, or in bunched masses of fine acicular crystals, odorless, and of a taste at first bitterish, but later

syptic." (Pelletier, Hesse, Winckler—Husemann, *Die Pflanzenstoffe*.) According to Pelletier, it is soluble in 375 parts of water at 13° C.; according to Hesse, in 1285 parts at 12° C.; while Dr. S. Weir Mitchell found that a specimen prepared by Merck dissolved in 1000 parts, one prepared by Powers & Weightman in 4000 parts, one of unknown European manufacture in 2100 parts, of distilled water at 60° F. Its saturated solution in boiling water on cooling fills with crystals. Concentrated nitric acid dissolves narceine with a yellow color, and the solution on being heated gives off reddish fumes; iodine makes with it a bluish-black mass, which forms a colorless solution in boiling water, but on cooling separates; with concentrated sulphuric acid narceine strikes a brown color, and finally makes a clear yellow solution (Husemann).

PHYSIOLOGICAL ACTION.—According to Baxt (*Reichert's Archiv*, 1869, p. 126), three or four centigrammes (0.46 to 0.62 gr.) of narceine, when injected into a frog, produce, in from ten to fifteen minutes, a semi-comatose condition, in which the batrachian makes no resistance or effort when laid upon his back or in other unnatural position. The respiration and circulation are not disturbed. The frog can be aroused by strong irritation, and when awake seems perfectly conscious. In three to six hours he comes out of his lethargic condition apparently unaffected. Albers (*Virchow's Archiv*, vol. xxvi.) found that one grain produces in the frog sleep, reflex and spontaneous convulsions, and, after seventy-four hours, death. According to Ott, the convulsions are chiefly spinal, the muscles also being affected. Dr. S. Weir Mitchell (*Amer. Journ. Med. Sci.*, Jan. 1870) found nine grains of the alkaloid to have very little effect upon pigeons, causing only abnormal quietness. In Baxt's experiments upon rabbits and guinea-pigs, fifteen centigrammes (2.3 gr.) had no perceptible influence; and on dogs Dr. S. Kersch (*Schmidt's Jahrbücher*, Bd. cxli. p. 15), and also Dr. Harley (*The Old Vegetable Neurotics*, p. 143), found moderate doses (26 ctgr., Kersch) equally inert. In a mouse (Harley) one-half grain caused tranquil sleep, with, after a time, tremors, from which the animal recovered, to be taken suddenly, some hours later, with fatal convulsions. At the post-mortem the tubules of the kidneys were found completely choked up with the alkaloid, which had crystallized in them and produced a mechanical suppression of urine, to which death was probably due. Schroff (quoted by Rabuteau), Fronmüller (*Schmidt's Jahrbücher*, Bd. cxli. p. 15), Harley, Mitchell, and Da Costa (*Pennsylvania Hospital Reports*, 1868), have found narceine to act very feebly upon man. Harley gave one grain hypodermically, Da Costa two and one-half grains by the mouth, and Mitchell took five grains himself, with the result of only causing some headache; and Fronmüller has exhibited as much as twenty grains with equally negative results.

These investigations are in close concord, and seemingly conclusive; and the study of Dr. Da Costa upon man was very full and exhaustive.

They are opposed by a number of seemingly equally conclusive investigations made by various French and German observers. Much of the interest that has been manifested in the alkaloid arose from the assertion of Claude Bernard in 1864 (*Archives Générales*, 6e sér., t. iv. p. 459) that it is the most pleasant and certain hypnotic of any of the opium alkaloids. He experimented upon dogs, guinea-pigs, rats, pigeons, sparrows, and frogs, and in all of them there was produced deep sleep, closely resembling natural sleep, with benumbed but not destroyed sensibility. The irritability of the morphine-sleep was wanting, and no secondary depression followed. Seven to eight centigrammes (0.8 to 1.2 gr.) was sufficient to throw a dog into the profoundest slumber. As early as 1852, Lecomte (Husemann, *Die Pflanzenstoffe*, p. 176) had affirmed that 0.1 grm. (1.53 gr.) of narceine thrown into the jugular vein of a dog would produce deep sleep, and very recently Rabuteau has confirmed the results of Bernard. Further, Behier (*Bull. Thérap.*, t. lxxvii.), Debout (*Ibid.*), A. Eulenberg (*Schmidt's Jahrbücher*, Aug and Oct. 1866), and Liné (*Journ. de Pharm. et de Chim.*, 4e sér., t. iii.) also assert as the result of experience that narceine, in doses of one-half grain to a grain, produces in man pleasant, persistent sleep. Rabuteau (*loc. cit.*) also agrees with this, except in placing the dose somewhat higher,—viz., at from ten to twenty centigrammes (1.53 to 3.06 gr.). Oettinger (*Das Narcein*, Diss. Inaug., Tübingen, 1866) also asserts that decidedly larger doses of narceine than of morphine are required to obtain any action.

As seemingly these opposing results are all true, the only possible explanation is that different substances were used by the different sets of observers under the one name. As the greatest care was practised by Harley and Mitchell in obtaining the alkaloid pure, and as Claude Bernard states expressly that the substance used by him was soluble in twenty parts of water, it is probable that the former observers really had, and that Bernard did not have, the narceine of Pelletier.

It is, at any rate, a very plain deduction from the above facts that if it be so difficult—nay, impossible—to obtain in commerce a uniform reliable narceine, it is not proper to use it as a medicine.

CODEINA. U.S.

Albers found that one grain of the muriate of codeine would produce in the frog, twenty minutes after its injection, tetanic cramps, alternating with convulsions, evidently reflex, since the slightest touch would call them forth. After a time the convulsive excitement grew less and less, the fore feet lost their sensitiveness first, but finally a paroxysm could no longer be provoked by touching the hind feet. The pupils at this time were widely dilated. Death occurred by failure of respiration, the heart continuing to beat a quarter of an hour after the extinguishment of all other movements. In Woldemar Baxt's (*Reichert's Archiv*, 1869, p. 125) experiments, three centigrammes (.045 gr.) pro-

duced in the frog deep sleep, lasting three or four hours. On awaking, the frog seemed more sensitive than natural to external irritation. Six centigrammes produced sleep more quickly, and following the deep sleep a stage of excessive sensitiveness, during which external irritation produced repeated cramp-like contractions. M. Wachs (quoted by Husemann, *Die Pflanzenstoffe*, p. 163) observed phenomena similar to those detailed by Albers, but noted a peculiarity of gait in the frog preceding the convulsive stage, owing apparently to disturbance in the innervation of the adductors. Wachs also found that .01 gramme (0.15 gr.) produced in the pigeon only increased rate of respiration and sleepiness, while larger fatal doses caused restlessness, inability to stand, movements backward and in a circle, disturbance of respiration with gasping, cramps of single muscles, and finally convulsions, mostly clonic, frequently repeated, and followed by an adynamic condition, terminated by sudden death. In Dr. S. Weir Mitchell's experiments (*Amer. Journ. Med. Sci.*, Jan. 1870, p. 26), seven grains produced violent non-tetanic convulsions, ending fatally in one minute, and one grain caused similar symptoms, terminating fatally in eight minutes. Dr. Ott (*Opium Alkaloids*) found that the convulsions in the frog are spinal, but that the muscles are affected.

According to Husemann (*loc. cit.*, p. 133), Kunkel, in 1833, from his experiments arrived at results similar to the recent ones of Bernard. The latter observer found that five centigrammes (.075 gr.) produced in dogs a sleep similar to, but not so profound as, that of morphine, with less benumbing of sensation, and not followed by any symptoms of depression.

These results have been called in question by Harley, and it seems most probable that Claude Bernard used something more than codeine in his experiments. Certainly Harley found that one to two grains of the alkaloid produced in the dog disturbance of respiration, languor, and convulsive twitchings, but no sleep. Moreover, Husemann states that, after fatal doses, Wachs observed similar symptoms in the dog and in the rabbit, as follows: falling of the head, trembling, spasmodic movements of the eyes and lips, rarely trismus, movements in a circle and backwards, weakness of the legs, with hurried respiration and prominence of the eyeballs as prodromes; later in the poisoning there were severe convulsions, after one or many paroxysms of which great weakness developed, ending in death. Barnay, in experiments upon dogs, cats, and rabbits, found that the convulsions were the most prominent symptom (*De la Codeine*, Paris, 1877). Falck affirms (*Deutsche Klinik*, 1870) that there are two forms of poisoning produced by codeine, —the one tetanic and the other soporific,—corresponding apparently to the different results of various observers.*

* From what he says on p. 226, it is probable that Falck used two preparations of codeine, —one made in his own laboratory, the other obtained from Merck. It is not possible to determine from his text whether this had anything to do with the different results he obtained.

As a hypnotic in man, codeine has been used by Magendie, Berthe, Aran, Krebel, Reissner, Robiquet, and others, some of whom assert that the sleep produced by it is followed by nausea or other symptoms of depression, while others deny this. It does not seem necessary to discuss in detail the researches of the authorities quoted, but it may be well to give the results of one or two of those observers more in full.

Robiquet in a series of experiments found that doses of 0.01 to 0.03 gramme (.15 to .46 gr.) produced a feeling of contentment, calmed nervousness, and induced refreshing sleep, while 0.1 to 0.2 gramme (1.53 to 3.07 gr.) caused deep sleep, followed by nausea and vomiting; 0.1 gramme (1.53 gr.) caused in children very alarming symptoms. Harley has found in a number of experiments that, given by the mouth, codeine is a very uncertain and feeble hypnotic, four grains producing simply accelerated pulse, contracted pupils, and some giddiness, followed by nausea and vomiting. When the drug is given subcutaneously, "somnolency," he states, "is a more prominent effect, but only occurs in certain individuals." His hypodermic dose is one to two grains. On the other hand, Dnorzak and Heinrich found that codeine in doses of 0.1 gramme caused gastric uneasiness and pain, some salivation, nausea, heat, and feeling of weight in the head, some confusion of thought, very marked reduction of the pulse-rate, and very marked tremors affecting the whole body; and Mitchell took five grains of the alkaloid without inducing other effects than a rise of twenty per minute in the pulse-rate, nausea, slight giddiness, and a sense of heaviness about the head. Dr. A. S. Myrtle records (*Brit. Med. Journ.*, 1874, i. 478) a case of severe poisoning by four grains of codeine prepared by the Messrs. Smith of Edinburgh. There was first vascular excitement and exhilaration, then depression with great anxiety, nausea and vomiting, pale, cool, clammy skin, slight contraction of pupil, and sleeplessness, with slight delirium. Two cases of rather serious poisoning by commercial codeine, in which each patient took eight grains of the alkaloid, have been reported; one in the *Brit. Med. Journ.*, 1888, ii., and one in the *New York Med. Record*, xliv., 1893.

It is very evident that these various observers have not had the same principle. In my own experience, codeine, prepared by Powers & Weightman, has failed to act in grain doses as a hypnotic. I have found it of some value in half-grain doses in quieting bronchial irritation. It is very evident that under the name of codeine various substances have been and are sold, and have been used by different physiologists and clinicians. I have given the codeine of Powers & Weightman in grain doses without producing any marked influence unless in allaying bronchial irritation. Nevertheless, Knoll & Co.'s codeine is said to be active in doses of less than half a grain; it probably contains morphine. For papers recommending codeine for the relief of abdominal pain, the

cough and distress of *phthisis*, and the general distress of *hypochondriasis*, see *Brit. Med. Journ.*, 1888, vol. i., and *Therap. Monatsh.*, 1889.*

The remaining active principles of opium being objects of physiological rather than of clinical interest, I shall discuss their physiological actions alone.

Narcotine.—Although in Dr. Albers's experiment (*loc. cit.*, p. 244) one grain of narcotine proved fatal to a frog without the production of convulsions, yet the united testimony of Claude Bernard (*loc. cit.*, p. 462), of Baxt (*loc. cit.*, p. 124), of Rabuteau (*loc. cit.*, p. 266), of Mitchell (*loc. cit.*, p. 23), and of Ott (*loc. cit.*) shows that in the lower animals this alkaloid produces, when given in sufficiently large dose, active spinal convulsions. In small dose (one-half grain) it causes, according to Albers and to Baxt, in frogs a semi-comatose state. In larger dose (1.2 grains) the last observer found it to induce in the same batrachian very decided convulsions, similar to those of morphine-poisoning. Dr. Mitchell states that from two to three grains produce violent and fatal convulsions in the pigeon. Claude Bernard ranks narcotine above morphine and codeine, next to papaverine, as a convulsant in the lower animals. Yet Orfila found thirty grains necessary to kill a dog, and Baxt has given about two grains to rabbits and to guinea-pigs without producing any symptoms.

Man is no more sensitive to narcotine than are the lower animals, if indeed he be as sensitive. Twenty and thirty grains of it have frequently been taken without effect, and doses of one hundred and twenty grains are said to have been exhibited with no greater result.†

Thebaine, or Paramorphine.‡—Magedie, Orfila, Albers, Baxt, Claude Bernard, F. W. Muller (*Das Thebain*, Diss. Inaug., Marburg, 1868), Harley, Fraser, Mitchell, Rabuteau, and other observers, all agree as to the very great similarity between the action of thebaine and that of strychnine. Falck (*Deutsche Klinik*, 1869) divided the general symptoms produced by the poison in mammals into three stages: the prodromal period, in which there was restlessness, combined with a desire to creep into corners, urination, increased frequency of respiration, and

* *Apocodeine*, a derivative of codeine, discovered by Matthiessen and Wright in 1869, has been employed by Dujardin-Beaumetz as an expectorant in a manner similar to apomorphine. For further information concerning it the reader is referred to *Monatsh. f. Prakt. Therapeut.*, iv., 1892-93; *Compt. Rend. Soc. Biol. de Paris*, v., 1893; *Provincia Méd. Lyon*, 1893, vii.

† *Coturnine* and *Hydro-coturnine* are derivatives from narcotine, which have been studied physiologically by Dr. Ralph Stockman (*Rep. Lab. Royal College Phys. Edinburgh*, iv., 1892) and found to be very similar in their action to narcotine. See also E. A. Falck, *London Med. Record*, i. 218.

‡ Dr. Ralph Stockman (*Rep. Lab. Royal College Phys. Edinburgh*, iv., 1892) has found that the combination of methyl sulphate with thebaine produces a compound which greatly resembles in its physiological action thebaine, but is less tetanizing and more paralyzing.

some stiffness of the leg; the second stage, in which there were violent strychnic convulsions, greatly interfering with respiration, and sometimes producing cyanosis; and the third period, in which there was paralytic muscular weakness, with apparent death, ending, after a time, in real death. The third stage was usually momentary, and seems to me to have been merely the dying, which occurred when the animal was exhausted and cyanosed by the convulsions. A notable symptom of thebaine-poisoning is the increase of bodily temperature, which Falek found to amount to from $\frac{1}{4}^{\circ}$ to 3° C. On pigeons (Falek and Ott) thebaine acts as upon mammals, and in frogs it produces the most violent tetanic spasms. The convulsions are undoubtedly spinal, as they occur after section of the cervical cord. See also Carl Grimm, *Inaug. Diss.*, Kiel, 1891.

The only detailed study of the physiological action of thebaine yet made is that of I. Ott (*Boston Med. and Surg. Journ.*, April, 1875), who found that the alkaloid does not directly affect the motor or sensory nerves or the striated muscles. The same observer also determined that thebaine exerts no influence on the inhibitory cardiac nerves, but does increase the arterial pressure by stimulating the vaso-motor centres, and probably also by stimulating the intra-cardiac ganglia. Thebaine is undoubtedly an exceedingly active poison. According to Albers, less than half a grain will cause violent tetanus in a frog, and in Ott's experiments .011 grain produced very decided symptoms in the same animal. Harley found two grains sufficient to kill a bitch, and in Falek's experiments a grain and a half injected hypodermically killed a dog in ten minutes. The alkaloid must act upon man as upon the lower animals; yet Frommüller (*Klin. Studien der Nark. Arzneimittel*, Erlangen, 1869) affirms that he has given it in as high as six-grain doses without producing any symptoms, and that Professor Leidesdorff (*Wiener Med. Wochenschrift*, No. 34, 1868) had had similar results. Rabuteau is said to have taken 1.5 grain without decided symptoms. On the other hand, Eulenberg found one-four-hundredth of a grain to cause increased respiration, pulse-rate, and temperature, with sometimes wide dilatation of the pupil (quoted by Ott). It seems impossible to avoid the conviction that the drug used by Frommüller must have been either very impure or else not thebaine at all. Husemann (*Arch. f. Exper. Path. Pharm.*, ix. 422) has found chloral strongly antidotal to toxic doses of thebaine.

Papaverine.—A great deal of discrepancy exists among observers as to the physiological action of papaverine, obviously dependent upon variations in the purity of the specimens which they have used. Schroff and Hoffmann believe it to be inert in man, since the latter observer took about seven grains without any effect being induced.

Albers and Claude Bernard claim that on animals it acts as a convulsant resembling thebaine; while Baxt asserts that in frogs it

produces profound sleep, with great slowness of the heart's beat, but without tetanus, and that it even acts as an antitetanic in the poisoning of codeine and morphine. He also finds that rabbits and guinea-pigs bear enormous doses of it. Rabuteau says two to three centigrammes produce violent convulsions in the frog, but twenty-five centigrammes in the dog cause no symptoms; yet in Baxt's experiments four to ten centigrammes served to cause profound coma in the latter animal. Ott affirms that it is both narcotic and convulsant, and produces a condition of the muscles similar to that caused by veratrine. These statements are irreconcilable, and no opinion can be arrived at until new researches, prefaced by a rigid chemical study of the alkaloid used, have been made. See also Johann Jersen, *Inaug. Diss.*, Kiel, 1891.

Laudanine, discovered by Hesse (*Annalen der Chemie und Pharmacie*, viii., Supplement. Bd., p. 272), has been elaborately investigated by Professor Falck, of Marburg* (*Deutsche Klinik*, 1874, p. 298). He finds that there are three stages of its poisoning: first, hurried respirations, pupils contracted or dilated, muscular twitchings and convulsive tremblings; second, convulsions closely resembling those of strychnine-poisoning; third, adynamia, apparent death, and finally death from failure of respiration, the heart being the last part of the body to die. According to Carl Dose (*Kiel Thesis*, 1890), laudanine produces alterations of the arterial pressure by stimulating the vaso-motor centre in the manner in which strychnine acts. Fubini and Benedicenti (*Archiv. Italien de Biolog.*, xvi., 1891) state that it is a paralyzant to the cardiac inhibitory fibres of the vagus.

Porphyrizine, according to Albers, acts upon the frog as the most powerful of all the convulsant opium alkaloids. Baxt (*loc. cit.*, p. 123) found it in doses of two to three milligrammes (.030 to .045 grain) to throw the frog into a semi-comatose condition, followed in fifteen to twenty minutes by most violent convulsive excitement. In sparrows one milligramme (.015 gr.), and in pigeons a larger dose, produced violent tremors, lasting ten to fifteen minutes, and followed by a state of semi-coma. In guinea-pigs ten to twenty milligrammes (.15 to .30 gr.) and in rabbits a one-fourth to one-third larger dose, caused violent tetanic cramps; larger doses produced speedily fatal convulsions. According to Schroff, 1.5 grains are without influence upon man.

Cryptopine, according to Harley, causes in dogs wild delirium, with dilated pupils, followed by tetanic spasms. In the mouse, small doses produce some delirious excitement, followed by somnolency; while large doses cause heavy sleep, and death from failure of the respiration.

* The following is the minimum fatal dose of alkaloids for rabbits, per kilogramme (2 lb. 5½ drms.) of weight, as determined by Falck: strychnine, 0.0006 gramme; thebaine, 0.012 grm.; laudanine, 0.025 grm.; hydrocotarnine, 0.16 grm.; morphine, 0.72 grm.

In the more detailed investigation of Immanuel Munk (*Wirkung des Cryptopin*, Inang. Diss., Berlin, 1873) it was found that the convulsions did not occur when artificial respiration was performed, and are, therefore, probably not spinal. The death was preceded by loss of reflex excitability from spinal depression, and was due to respiratory paralysis. Enormous doses also killed the cardiac muscle. A grain and a half injected beneath the skin by Harley caused in some persons intense drowsiness, in others very slight symptoms. According to Dr. Ott, it is narcotic, exciting and then depressing spinal motor centres, paralyzing spinal sensory centres, lessening functional activity of the motor nerves, and lowering heart-action by an influence on its muscle.

Meconine, according to Albers (*loc. cit.*, p. 248), produces in (0.045 grm.) the frog mild tremors, lessening of sensation, and finally death. On the higher animals its poisonous action is not very great. Orfila injected 0.06 grm. (0.9 gr.) into the jugular vein of a dog, without effect. Harley gave two grains hypodermically to the same animal, with no further result than a little abnormal quietness. According to the same observers, subcutaneous injections of fourteen grains have no effect on the horse, but one-sixth of a grain produces very decided hypnotism in the mouse. On man, Dublanc (*Pharm. Centralblatt*, 1832), Schroff (*Medicin. Jahrb.*, 1870), Frommüller (*Klinische Studien Narcot. Arzneien*), and Harley have found meconine, when given by the mouth, inert in doses varying from one to eighteen grains. Harley, however, asserts that in doses of one to two grains given hypodermically it acts upon man as a very excellent hypnotic; but Frommüller has injected nearly two grains with entirely negative results.

In regard to the action of *Pseudomorphine* and *Opiatine* we have little or no knowledge. *Meconoisine*, a neutral principle, has been found by Ralph Stockman to be a tetanizant. Sertürner, the discoverer of *Meconic Acid* (quoted by Albers), found it in his experiments to be actively poisonous; but Sömmering and Albers have come to an opposite conclusion. Large doses (one or two grains) do, however, affect frogs, although slowly, inducing a stupor-like condition, with convulsions.

HYOSCINE HYDROBROMAS—HYOSCINE HYDROBROMATE. U.S.

The alkaloid hyoscyne is a non-crystallizable nitrogenous body, originally extracted from the seeds of the *Hyoscyamus niger*. The hydrobromate occurs in minute, colorless, rhombic crystals, which are freely soluble in water and also in alcohol. The taste is bitter, but not sufficiently intense to be distinctly perceived in the minute doses used in medicine.

PHYSIOLOGICAL ACTION.—The fact that numerous observers have asserted that the impure amorphous hyoscyamine of commerce is more

powerful than the pure crystallized alkaloid led me to believe that hyoscine, which constitutes a large portion of the so-called impure hyoscyamine, must be diverse in its action from hyoscyamine. Acting upon this, in 1884 I made a careful physiological study of hyoscine (*Therap. Gaz.*, Jan. 1885).^{*} In the frog it produces a general motor and reflex paralysis, progressively increasing until death from failure of respiration. When recovery occurs, there is no stage of tetanus following the palsy. Neither the muscles nor the motor nerves are sensibly affected, and the paralysis is dependent upon depression of the motor centres of the apinal cord. No evidence could be obtained of affection of the sensory side of the nervous system. In mammals, the symptoms produced are loss of muscular power, disturbance of respiration, and marked tendency to stupor, with finally death by asphyxia. The alkaloid has very little effect upon the circulation, though after enormous doses when life is

^{*} Partial physiological studies of hyoscine have recently been made by Gley, Rondan, Mairat and Combemale (*Compt. Rend. Soc. Biolog.*, 1887), A. Sohrt (*Inaug. Diss.*, Dorpat, 1886), Claussens (*Inaug. Diss.*, 1883), and Kobert (*Archiv f. Exper. Path. Pharm.*, 1887), the paper by Kobert being apparently a restatement of the work done by his pupil Sohrt. Mairat and Combemale found that monkeys when poisoned by it gave evidences of the presence of hallucinations, such as are sometimes produced in man. The results obtained by the other investigators are in some points so different from those which I arrived at myself as to indicate that we were working with materials which were not exactly the same.

In a former edition of this work I expressed the suspicion that, owing to the difficulty with which hyoscyamine is separated from hyoscine, much of the hyoscine of commerce was more or less contaminated with hyoscyamine. Ernst Schmidt (*Pharm. Journ. and Trans.*, October, 1891) has found, as the result of careful chemical study, that most of the hyoscine hydrobromate in commerce is in fact the hydrobromate of scopolamine, an alkaloid which exists in the root of various species of the genus *Scopolia*. This discovery indicates very clearly the cause of the discordant physiological and therapeutic results which have been obtained by investigation. My own experiments, and also my own therapeutic studies, have been made with the hyoscine of Merck, which I believe to be a pure article. Claussens, like myself, found that hyoscine does not paralyze the pneumogastric nerve. P. Rondan affirms that he has seen such paralysis caused by very large doses. Sohrt and Kobert came to a similar conclusion, Kobert stating that when hyoscine is placed directly upon the heart of the frog which has suffered diastolic arrest from muscarine systolic contractions are re-established, and also that when it is applied to the exposed heart of the frog it prevents the production of diastolic arrest by galvanization of the vagus centre. In further experimentation upon dogs and cats, it was found that when the vagus with its accompanying nerves was cut galvanization of the central end caused no sinking of the blood-pressure if hyoscine had been previously administered, and Kobert deduces from this that hyoscine paralyzes the vagus nerve. The experiment evidently proves no more than that under the influence of hyoscine the depressor nerve is no longer able to cause vaso-motor dilatation. It is possible that directly applied to the frog's heart hyoscine may paralyze the vagi, and yet its influence upon those nerves be so slight as not to be apparent when the alkaloid has been absorbed and is acting upon the whole organism. Almost all clinical observers have noted that the pulse becomes slower rather than more rapid under the influence of hyoscine, and this assuredly shows, too, that the drug has no marked paralytic action upon the vagus, for the pulse of vagus-paralysis is of necessity very rapid. Kobert also found that hyoscine has no influence upon the apinal cord of the frog when given in doses of one-five-hundredth part of its weight; but, as the paralyzing influence of the drug in my experience was marked with one-one-thousandth part of the frog's weight, while one-five-hundredth part caused complete loss of reflex activity with absolute paralysis, and death from respiratory paralysis, it is evident that Kobert, or rather his pupil, Sohrt, had something which was not pure hyoscine.

maintained by artificial respiration the vaso-motor system is finally paralyzed. On the heart itself hyoscine acts as a very feeble depressant; it does not paralyze the pneumogastrics. In man the symptoms which are produced by decided doses are dryness of the mouth, flushing of the face, great sleepiness, associated in some cases with semi-delirious mutterings, and a feeling of giddiness like that of intoxication. The respirations are lessened in frequency, and the pulse-rate is usually somewhat diminished;* mydriasis is usually, but not always pronounced. After very large doses the symptoms mentioned are more intense; the pulse becomes slow and full, but, according to the sphygmographic tracings of Dr. J. B. Andrews, without alteration of tension, the pupils dilated, the mouth and throat excessively dry, and the voice hoarse or even partially suppressed, probably from paralysis of the vocal cords. The respirations are slow and full, and are said by Dr. H. M. Wetherill (*Therap. Gaz.*, i. 199) to be sometimes Cheyne-Stokes. The face and the general surface of the body are suffused, muscular relaxation is pronounced, and loss of co-ordination usually very evident. The skin, so far from being abnormally dry, is commonly bathed in perspiration. Several observers assert also that there is a rise of temperature. Sometimes the delirium is active, accompanied by visual hallucinations, and clonic convulsions with opisthotonos have been noted (*Therap. Gaz.*, Feb. 1889). Dr. H. A. Hutchinson (*Alienist and Neurologist*, iii. 539) took a quarter of a grain of very impure hyoscine: quiet coma with entire muscular relaxation was produced, and lasted eleven hours. It is evident that in man, as in animals, the *motor tract of the spinal cord and the cerebral cortex are depressed* by this alkaloid, which is also a *respiratory paralyzant*. No case of fatal poisoning is on record. On the other hand, very severe symptoms are alleged by several physicians to have followed the use of very small doses of the drug. The fiftieth of a grain has several times caused very alarming symptoms (see Carey, *Univ. Med. Mag.*, vol. i.). Dr. O'Hara (*Therap. Gaz.*, ii. 26) saw one-ninety-sixth of a grain administered hypodermically produce very severe disturbance, lasting for twenty-eight hours, with total lack of remembrance of occurrences which took place during the seven hours following the injection; while Dr. Root (*Therap. Gaz.*, vol. ii.) asserts that one-three-hundredth of a grain given by the mouth produced violent poisoning, and even one-twelve-hundredth very pronounced symptoms. The dispensing of these exceedingly minute quantities of a drug requires so much care that it is extremely probable that more of the alkaloid was given than is alleged. A disagreeable symptom which has been noted by several observers, and which I myself have seen produced by hyoscine, is paralysis of the pharynx, and probably also of the laryngeal muscles. The importance of this action was made very apparent to me by my noticing it in a case of

* It has been noted a little accelerated. (Case, *Therap. Gaz.*, 1889, Dr. J. S. Gibb.)

malignant scarlet fever with great diphtheritic exudation, in which the hyoscine was given with immediate relief of the persistent delirious insomnia, but in which under the influence of the drug the dyspnea rapidly increased in intensity and in an hour or two ended in death.

According to Mr. John Tweedy (*Lancet*, Dec. 1886), the hydrobromate of hyoscine is a very powerful local mydriatic, a half of one per cent. solution rapidly paralyzing accommodation and dilating the pupil. It is said that it does not produce any irritation, and that its maximum effects are reached in one-third the time necessary for those of atropine, and are more permanent and less affected by eserine. MM. E. Gley and P. Rondeau (*Compt.-Rend. Soc. Biol.*, 1887, iv. 56) have found that the mydriasis is not prevented by previous destruction of the cervical sympathetic in the rabbit, and that irritation of the sympathetic nerve will increase the dilatation.

The results of my experiments with hyoscine upon the lower animals led to its use as a hypnotic, and it has proved itself a valuable therapeutic agent, especially useful in cases of *insomnia* with delirious excitement, such as occurs in *acute mania* and in other forms of *insanity*. Under these circumstances its effects in producing sleep are often extraordinary: it has been in my experience especially valuable in those cases in which morphine intensified the excitement, and I have frequently seen it succeed after the failure of both chloral and morphine. In *delirium tremens* it in some cases has acted most favorably. Since the publication of my memoir, hyoscine has been very extensively used, with in most cases favorable results. (See J. B. Andrews, *Amer. Journ. Insan.*, Oct. 1885; Dr. J. Mitchell Bruce, *Lond. Pract.*, vol. xxxvi., 1886, p. 321; also various papers in *Therap. Gaz.*, vol. ii.) As early as 1881 Professor Edleson (*Centralbl. f. Med. Wissensch.*, 1881, 416) stated that hyoscine is useful in *asthma*, and also in *whooping-cough*, and Dr. Rudolph Gnauck (*Centralbl. f. Med. Wissensch.*, 1881, 801, *Charité Annalen*, 1882, 488), that it had a powerful hypnotic influence.

The insomnia which is especially relieved by hyoscine is that which is connected with cerebral excitement when sleep is banished by a continual whirl of thoughts or mental images. Excellent effects are sometimes achieved in cases of nervous excitement with or without insanity, by giving very minute doses of hyoscine, which allay the excitement and produce quiet without causing sleep. Dr. Bruce (*loc. cit.*) and Tirard (*Practitioner*, Feb. 1887) assert as the result of their experiments that hyoscine is an entirely safe hypnotic in cases of severe kidney-disease when morphine cannot be employed. Dr. Bruce also states that he has used the drug with good results when an exceedingly feeble condition of the heart forbade chloral.

Probably through its influence upon the spinal centres hyoscine is a most useful remedy in all cases of *sexual excitement*, such as *nymphomania*, *spermatorrhœa*, and allied affections. It is the most certain remedy that we have in ordinary cases of over-frequent seminal emis-

sions, which can almost invariably be controlled by the administration of $\frac{1}{128}$ to $\frac{1}{64}$ of a grain on going to bed. I have obtained the most pronounced relief in *paralysis agitans* attended with much aching pain by the use of hyoscine, and Erb has recently praised the drug highly in this disease (*Zeitschr. f. Therap.*, Aug. 1887). In most cases it should be given only at bedtime, as it is simply a palliative, and if used constantly is prone to lose its power. Erb has used it with advantage in various spasms. In one or two cases of *spinal accessory spasm* it has in my hands failed.

Hyoscine very rarely if ever causes other disagreeable after-effects than a little dryness of the throat, although occasionally some headache has been noted. Nausea, constipation, or other disturbance of the alimentary canal is never produced. The action of hyoscine given hypodermically is manifested inside of ten minutes, and lasts from about six to eight hours. In severe excitement, especially that of violent insanity, the dose should be repeated every six or eight hours. The remedy being free from irritant properties, no local ill effects follow its hypodermic administration. The dose for hypodermic use may be set down at from $\frac{1}{16}$ to $\frac{1}{32}$ of a grain. Excessive susceptibility to the action of hyoscine being a not infrequent idiosyncrasy, it is best to give at first amounts below the minimum dose here stated. The tastelessness of hyoscine makes it exceedingly easy to administer it to insane or other patients without their knowledge.

Hyoscine is with difficulty separated from its sister alkaloid hyoseyamine, and it is essential for successful results that the practitioner have a pure article of hyoscine. In my own practice I rely solely upon that made by Merck, of Darmstadt.

CHLORAL—CHLORAL HYDRATE. U.S.

Chloral, which is itself not used in medicine, is an oily liquid which at the ordinary temperature gives off pungent fumes, and which is manufactured by the action of chlorine on alcohol. United with water, this oily liquid is converted into a hydrate.

Chloral Hydrate,* or *Chloral* of the U.S. Pharmacopœia, is a volatile, crystalline solid, of a hot, burning taste, insoluble in cold chloroform, but very soluble in water, ether, and alcohol. It occurs generally as transparent, colorless tablets, but sometimes in acicular or even in rhomboidal crystals. The compound of chloral and alcohol,—*Chloral Alcoholate*,—which resembles closely the hydrate, can be distinguished at once by its insolubility in water and its solubility in cold chloroform.

If an alkali be added to a solution of chloral hydrate, it breaks up

* There is a chloral hydrate containing a very small proportion of water, which is insoluble in the latter menstruum. (*Gmelin's Hand Book*.) For a case in which chloral was detected in the stomach after death, and for methods of examination, see *Edinb. Med. Journ.*, Oct. 1874.

into formic acid and chloroform, which latter, when water has been the solvent, at once separates in the form of oily drops.

PHYSIOLOGICAL ACTION.—When applied to a part, chloral acts as an irritant; and probably for this reason it sometimes, when given by the mouth, causes vomiting, or even purging. When it is given to man or other mammals in moderate doses, the most prominent result in the great majority of instances is a quiet sleep, as closely allied as possible to natural sleep. The subject can readily be aroused from the lighter degrees of this, waking to full consciousness, but soon dropping off again when left quiet. The pulse is in this degree of action not affected, or is rendered a little slower; the pupil is contracted, but becomes normal so soon as the subject is awakened; the respiration is deep, full, and regular. When larger amounts are given, the sleep is much deeper, and may pass into profound coma; the respirations fall in number; the pulse is weakened and rendered slower, but may become rapid and irregular if the dose has been toxic; the temperature is reduced; the muscular system is relaxed, and both sensibility and reflex action are diminished. If a fatal dose has been given, all these symptoms are intensified: with coma, intense muscular relaxation, weak, thready pulse, and a pupil contracted at first, but afterwards dilated, the animal gradually sinks into death, paralyzed and anæsthetic. The immediate cause of death is usually a centric paralytic arrest of respiration; but in many cases there appears to be a simultaneous arrest of the cardiac action, and it is probable that fatal syncope may at times occur. At the post-mortem examination, congestion of the meninges and substance of the brain and cord, and of the lungs, is commonly found. The blood is thought by Richardson (*Medical Times and Gazette*, Sept. 4, 1870) to coagulate less firmly than when normal.

The most constant and prominent of all the symptoms produced by moderate doses of chloral is sleep: this is without doubt due to a direct action of the drug upon the cerebrum. In most cases, as already stated, it is quiet, but sometimes it is restless, and in man has even occasionally been wildly delirious; although it is somewhat uncertain whether the latter condition may not have been due to impurities in the drug. It seems to be well established that in the milder degrees of this sleep there is no anæsthesia. Demarquay (*Bulletin Thérap.*, tom. lxxvii. p. 307) claims that hyperæsthesia very commonly follows the exhibition of small doses. Bouchut (*New York Med. Gazette*, Dec. 1870), Dieulafoy and Krishaber (*Amer. Journ. Med. Sci.*, Jan. 1870), Giovanni and Hanzoli (*Schmidt's Jahrbücher*, Bd. cli.), and Rajewsky (*Ibid.*) confirm this, while Liebreich and Labbé* deny it, and Hammarsten, who has noticed such hyperæsthesia, is inclined to think it apparent rather than real. I myself have seen this hyperæsthesia, and there can be no doubt

* He has noticed it, however, in a single case, confined to the ears. (*Archives Générales*, 1870, tome xvi. p. 338.)

that it is an occasional, if not a constant, phenomenon. Rajewsky (*loc. cit.*) states that there is in frogs a corresponding period of over-excitability of the reflex centres, and that in rabbits he has noticed a glowing heat borne without much complaint, when pinching would produce violent outcries. In *very large* doses chloral produces anæsthesia; but, unless the amount employed be so great as to be toxic, this anæsthesia is in most cases very trifling.

Motor System.—The paralysis and loss of reflex excitability induced by chloral are not muscular in their origin, for Labbé has found that after death the muscles respond perfectly to galvanism. Both Labbé (*loc. cit.*) and Rajewsky (*loc. cit.*) have found that the motor nerves are in no wise affected by large or even fatal doses of chloral, which must therefore act upon the spinal cord to produce the paralytic phenomena. The experiments of Rajewsky have afforded positive confirmation of the conclusion arrived at by this process of exclusion; for he found that in the latter stages of chloral-poisoning direct irritation of the spinal cord gave rise to much less severe spasms than in the unpoisoned animal. Before this paralytic stage is reached, as already stated, Rajewsky affirms that in the frog there is a period of increased reflex activity, and that at this time stimulation of the spinal ganglia shows that they are more susceptible than normal. The observer last named states that these phenomena occur just as freely after destruction of Setchenow's centre in the frog as before, and are therefore independent of it.

Circulation.—According to Demarquay, when chloral has been administered to animals there is evident enlargement and engorgement of all their blood-vessels; and Rajewsky* states that he has found sinking of the blood-pressure in rabbits from small as well as from large doses of the drug. On the other side, Labbé (*loc. cit.*, p. 341) asserts that the rabbit's ear grows pale after the injection of a very feeble dose. In man, Bouchut has obtained sphygmographic traces which he thinks indicate a primary increased arterial tension. Nancias, of Venice, has found the tension normal, but Anstie and Andrews (*American Journal of Insanity*, July, 1871) confirm the results of Bouchut when small doses are employed. Preisendorfer (*Deutsches Archiv*, xxv. 48), in a series of sphygmographic studies, thought there might be a brief primary rise of arterial pressure in man, as in animals, but under the full action of chloral the arterial pressure steadily sinks. After very large doses, according to both Andrews and Da Costa (*Amer. Journ. Med. Sci.*, April, 1870), the tracings indicate decidedly lessened arterial pressure. It would seem, however, from the researches of Dr. Cerna that it is not possible to elevate arterial pressure in curarized animals with any dose

* The work of Rajewsky was done under Professor Rosenthal, and the results, without the experiments, were published as an inaugural thesis. Of course half of its value is lost for want of the experimental records, and the subject needs re-investigation. I am acquainted with the pamphlet only through Schmidt's *Jahrbücher*.

of chloral; so that if any rise ever occur in the normal animal from chloral, such rise must be indirect and, probably, due to respiratory disturbance. The characteristic influence of therapeutic, and still more of toxic, doses is to produce a fall in the blood-pressure, usually accompanied with a lessening in the frequency of the heart's action, which Dr. Cerna believes to be largely due to an influence upon the cardio-inhibitory centres; although Rajewsky affirms that the slowing of the pulse in the frog and in the rabbit is produced after section of the inhibitory nerves, and is therefore independent of them. The fall of blood-pressure is probably owing in part to the vaso-motor paralysis, but perhaps in largest part to depression of the heart. The vaso-motor palsy is probably chiefly caused by an action upon the dominant centre, but Robert* (*Therap. Gaz.*, 1887) has shown that there is also, after a very large dose of the chloral, palsy of the coats of the vessels. When toxic doses have been employed, the heart, after numerous pauses, is finally arrested in diastole. Analogy indicates very strongly that this arrest is due to a direct influence upon the heart muscle or ganglia, and the researches of Drs. Sidney Ringer and H. Sainsbury (*Brit. Med. Journ.*, March, 1883) and of Dr. David Cerna (*University Med. Mag.*, Nov. 1891) seem to demonstrate (the contrary results obtained by Labbée notwithstanding) that when chloral is brought in direct contact with the isolated heart of the frog there is an immediate and persistent loss of power, ending finally in diastolic arrest.

In poisoning in man, the pulse has towards the last been very feeble, generally rapid and irregular, and even in some cases in which recovery has occurred it has been altogether absent for a time. The experiments of Ringer and Sainsbury are so concordant with this that I have no doubt that chloral is a *direct depressant to the heart*, and is capable of suddenly and unexpectedly destroying life, precisely as does chloroform.

Respiration.—In full doses, chloral lessens the number of respirations per minute, causing them to become slow and full; when toxic doses are taken this action becomes more and more marked, the rhythm is very much affected, and the respiration grows very irregular, and sometimes very rapid and shallow, until it ceases. As these phenomena occur equally after section of the vagi (Rajewsky), the influence of chloral must be exerted upon the respiratory centre at the base of the brain. Professor Charles Richet has found that toxic doses of chloral reduce very greatly the elimination of carbonic acid, at the same time that they lower the bodily temperature (*Arch. de Physiology norm.*, 1890, vol. ii.). So far as large doses are concerned, A. Gritzka (*Inaug.*

* With an elaborate technic, Robert caused to circulate through freshly excised organs defibrinated blood taken from the animal and propelled by an artificial heart with a fixed expenditure of force. Under these circumstances the addition of chloral to the blood markedly increased the rate at which it passed through the organs, a result only to be explained by the theory that the drug, by directly paralyzing the walls of the blood vessels, opened out the blood-paths.

Diss., Berlin, 1891) is in accord with this, although he claims that small doses increase carbonic acid elimination.

Temperature.—A most remarkable action of chloral is upon the temperature: in this point all observers are in accord with Dr. Richardson, of London, who has seen the temperature fall 6° F. in a rabbit which recovered. Bouchut has noticed a fall of 2° (C. ?) in an infant, and Da Costa and other observers have noticed slighter reductions of temperature in man after therapeutic doses. In a case reported by Dr. Levinstein (*Lancet*, i., 1874), after six drachms of chloral the temperature rose to 39.5° C. (102.1° F.), and subsequently fell to 32.9° C. (91.22° F.). Hammarsten has found that the fall of temperature is very rapid, 6° C. in an hour, and that it occurs in animals well wrapped up and laid in a warm place.

Tissue Change.—Julius Peiser (*Halle Thesis*, 1892), as the results of chemical experiments, finds that chloral hydrates increase the degeneration of albuminous tissues.

Summary.—Upon the cerebrum chloral acts as a powerful hypnotic; in full doses it acts as a depressant upon the centres at the base of the brain, and upon the spinal cord, and also causes slowing and weakness of the heart's action, probably vaso-motor paralysis, slowing of the respiration, and muscular weakness, with a certain amount of anæsthesia; in fatal doses it usually produces a gradual death by paralyzing the nerve-centres in the medulla, and thereby arresting respiration, although in rare cases it kills suddenly by directly paralyzing the heart, which always stops in diastole. Its action in very small doses is uncertain, but there is some evidence to indicate that it irritates or stimulates the spinal and the cardiac centres. On the vagi and on the motor nerve trunks it has no marked influence. It does not undergo the chloroformic decomposition by the alkali of the blood or in the system, and is eliminated as uro-chloralic acid.

Action as Chloral.—The conversion of chloral by alkalies in solution into chloroform and formic acid first suggested its use in medicine to Liebreich (*Wiener Medizinische Wochenschrift*, August, 1869); and the theory that its action is really due to chloroform generated by the alkalinity of the blood has been received with favor by Personne and other writers. The evidence by which this theory is to be disproved or established is twofold in its nature,—i.e., chemical and physiological.

Personne (*Journal de Pharmacie et de Chimie*, 1870), by distilling the blood of animals poisoned by chloral at 40° C., a temperature decidedly above that of the body, obtained chloroform; and his results have been confirmed by Pellogio (*Schmidt's Jahrbücher*, Bd. cli. p. 89) and other chemists, so that I think their correctness is not to be questioned. They are, however, not decisive, for it is possible that the chloroform may be formed during the distillation, owing to the comparatively high heat employed. This evidence is, then, to be thrown out, especially as Hammarsten (*Ibid.*, Bd. cli) has found that if chloral be mixed

with fresh blood and streams of carbonic acid be forced through it, no chloroform can be detected, but if the mixture be heated the latter can be obtained in abundance. Further, in dogs deeply poisoned with chloral the same observer examined the expired air and a portion of the blood without finding chloroform, although when a clyster of the anæsthetic was given to the poisoned animal chloroform could be detected in a few minutes in both the blood and the breath. In non-chloralized animals to which similar enemata were given, the chloroform could be found in the breath before anæsthesia was induced. Rajewaky (*Ibid.*, Bd. cli.), Amory (*New York Med. Journ.*, 1870), and Von Mering and Musculus (*Berichte Deutsches Chem. Gesell.*, 1875, i. 662) have confirmed these results: so that it may be considered settled that chloral mixed with blood at ordinary temperatures remains unaltered, and that in the most severe poisoning no chloroform can be detected either in the blood or in the expired air. Hammarsten examined the blood and expired air unsuccessfully, for chloral, in dogs poisoned with the drug; but Amory (*loc. cit.*, p. 616) has obtained from the blood acicular crystals, evidently of chloral. The exact fate of chloral in the system can scarcely be considered as established, but it is probable that it is eliminated with the urine, and at least partially in a changed condition. A. Tomascowicz recognized it in the secretion mentioned by means of the delicate isocyanphenol reaction* of Hoffmann (*Pflüger's Archiv*, ix. 35). Foltz and Ritter (*Comptes-Rendus*, lxi. 966) believed that they found sugar in the urine of chloralized animals, but both Von Mering and Musculus (*loc. cit.*, 663), and F. Echard† (*Archiv f. Exper. Pathol. und Pharm.*, xii. 276) have shown that the substance which reduces the copper solution will not undergo fermentation, and Von Mering and Musculus have separated it as *urochloralic acid* in colorless, shining needles, often arranged in star-like groups, soluble in water and in alcohol, insoluble in ether. The existence of this acid has been confirmed and its chemical properties studied by A. Borntraeger (*Inaug. Dissert.*, Marburg, 1879), and by E. Külz (*Arch. f. Gesamte Physiolog.*, 1882, 506), who found it destitute of hypnotic or other active physiological powers.

The physiological evidence is in strict accord with the chemical in showing that chloral is not converted into chloroform in the system. While chloral produces a longer and more intense sleep than does chloroform, the latter agent acts much more decidedly as an anæsthetic. Again, Djurberg (*Schmidt's Jahrbücher*, Bd. cli. p. 84) has shown that, while after chloroform-poisoning biliary coloring-matters appear in the urine, after chloral-poisoning none can be detected, and that when

* Many chemists have failed to find chloral for want of a delicate test. Dr. F. Ogston (*Edinb. Med. Surg. Journ.*, xxiv. 292) affirms that the sulphide of ammonium affords a means of recognizing minute amounts of the drug.

† Echard has also found that chloral will prevent the development of diabetes by the Bernard prick.

chloral is added to blood outside of the body no destruction of the red disks occurs.

As was first shown by Cohnheim, if the abdominal vein of a frog be opened and salt water be injected until almost all the blood is washed out and the circulatory system is filled with the foreign fluid, the batrachian will live from one to three days in apparently perfect health. Both Rajewsky (*loc. cit.*, p. 91) and Lewisson (*Reichert's Archiv für Anatomie und Physiologie*, 1870, p. 346) have found that upon these "salt frogs," with the circulating fluid completely neutral, the chloral acts precisely as in the normal frog.

I think the evidence which has been adduced completely disproves the chloroform theory, and forces assent to the proposition that chloral acts directly upon the organism.

THERAPEUTICS.—The results of the clinical use of chloral are in strict accord with its known physiological action. The indication which it most usefully meets is to induce sleep. The more purely nervous the wakefulness is, the more successful is this remedy. When from functional over-excitement of the brain due to excessive mental strain, or from anxiety or other kindred cause, the patient cannot sleep, chloral is by far our most valuable hypnotic. On the other hand, when severe pain causes wakefulness, chloral is of very little value,—at least in doses which I think safe. Sometimes even in these cases sleep will come, but it will very often be a restless, troubled sleep, with moaning or other indications of suffering; and it may be that the patient on awaking will complain that he has suffered more while sleeping than when awake.

In the sleeplessness occurring at times during convalescence from acute disease, chloral is very efficacious. In the early stages of fevers it is sometimes of advantage; Dr. Russell (*Glasgow Med. Journ.*, Feb. 1860) recommends it especially in the wild delirium of typhus in its earlier stages. In advanced fever-cases, when the symptoms are gravely adynamic, I conceive that the use of chloral would be very perilous. In *delirium tremens* it often induces sleep readily, but not rarely it fails, even in large dose. In the sleeplessness of acute puerperal or non-*puerperal mania* there is abundant testimony to the value of chloral. It must not be forgotten that chloral is a dangerous remedy when there is cardiac weakness; and when in any of the diseases just spoken of there is reason to suspect a fatty or even a feeble heart, great care must be exercised in the administration of chloral. Under such circumstances the dose of ten grains should not be exceeded, and should not be repeated more than once unless after an interval of several hours.

Dr. Lyon Playfair (*Lancet*, 1874, vol. i.) has introduced the use of chloral as a means of alleviating the sufferings of parturition, and has been followed to some extent by other practitioners. He affirms that it produces a drowsy state, from which the woman is aroused by the uterine contractions, which are almost robbed of their painful character.

So soon as the "pains" begin to be active he administers fifteen grains of the drug, repeating the dose in twenty minutes; thirty grains usually are sufficient, and he has never given more than a drachm during a labor. Towards the close, when the "pains" become very severe, inhalations of chloroform or of ether may be practised in the usual manner. It is affirmed by other obstetricians that in rigidity of the os chloral is often of great service, by aiding in the desired relaxation, and at the same time materially alleviating suffering.

On the whole, as a pure hypnotic chloral is indeed unequalled, and may be used in all cases when no contra-indication exists.

The second indication to meet which chloral may be employed is to relax spasm. For this purpose it has been used with advantage in puerperal and uræmic convulsions. It must be remembered that in many of these cases, although next to chloroform the best palliative, it is only a palliative, and must only be used to quiet the nervous disturbance until other remedies can have time to act. In tetanus it has been claimed that chloral is the remedy. Dr. Jos. R. Beck (*St. Louis Med. and Surg. Journ.*, June, 1872) has collected, of the traumatic form of the disease, thirty-six cases, with twenty-one recoveries, in which chloral constituted the whole or the major part of the treatment. References* are given below to fifty-six cases in addition; so that the figures stand forty-eight recoveries and forty-four deaths. These results do not seem to warrant the high estimate which has been set upon the value of chloral in tetanus. Dr. Macnamara (*Practitioner*, November, 1874) has employed the remedy in a different way from what is usual. Believing that it exerts very little control over the spasms, he has not used it for such purpose, but has used it simply as a hypnotic, giving the patient forty grains of it at bedtime, and only when the temperature rises above 101° F. a single dose of thirty grains in the morning. No other medicine is given, but the patient is made to swallow four ounces of milk with brandy every four hours, one egg being mixed with the milk morning, noon, and evening. He

asserts that in this way out of twenty consecutive cases (all traumatic?) occurring in natives of India he has saved seventeen. My own opinion is that no one single remedy affords the best chances in tetanus, but that a combined use of bromide of potassium, opium, and chloral should constitute the basis of treatment, the patient also being supported with food to the utmost. In strychnine and other toxic convulsions chloral is often of great value.*

In *trismus nascentium* Dr. Widenhofer (*Boston Med. and Surg. Journ.*, 1874) recommends it very highly. He says that in the Children's Hospital he formerly lost all his cases, but that by its use he has saved six out of twelve. He gives it to a young babe in one- and two-grain doses by the mouth, or, when the spasms prevent, in double the quantity by the rectum. In *chorea* chloral has been used sometimes with great advantage, more often, I think, with the result of simply diminishing temporarily the choreic movements, and sometimes without any effect. In my own experience the movements have generally returned with unabated violence so soon as its exhibition was suspended. As a nocturnal quietant and hypnotic, it would appear to offer very great advantages in cases of *acute chorea* in which speedy death is threatened from the incessant and violent movements; also in cases complicated with fractures, where a temporary lull is of importance.

In *puerperal convulsions* its use in large doses has met with a great deal of favor (see *Phila. Med. Times*, vol. iv.). A half-drachm may be exhibited at once, and half the quantity every hour or two *pro re nata*.

In the *convulsions* of children it has been employed with apparent good; in *cramps* in pregnant women it has been commended by Dr. Morgenstern (*Wiener Med. Presse*, Nov. 1871); in *singultus*, by Dr. Leavitt (*Amer. Journ. Med. Sci.*, April, 1871); in the spasmodic *nocturnal enuresis* of children, also, it may often be used with advantage (Dr. J. B. Bradbury, *Brit. Med. Journ.*, April, 1871); in *laryngismus stridulus* (Dr. Rehn, *Jahrbuch für Kinderkrankheiten*, 1871) and other spasmodic affections; in *nocturnal emissions* at bedtime it is of service (Gascoyno, *Brit. Med. Journ.*, 1872). In *whooping-cough* it would seem to be of very great value, as has been attested by Drs. Adams (*Lancet*, i., 1870), Murchison, (*Ibid.*, ii., 1870), Rigden (*Practitioner*, xxvii., 1870), and Waterhouse (*Ibid.*, Dec. 1870), and by various French observers. Small doses (two to eight grains), repeated at regular intervals during the day, are often very efficacious. Another plan, especially useful when the paroxysms are very severe at night, is to give a full dose at bedtime. When there is a tendency to bronchitis and pneumonia, chloral must be used with care, as in large doses it favors congestion of the lungs: yet Murchison saw a very threatening case, complicated with bronchitis and pneumonia, greatly benefited by its exhibition. In *asthma* it has sometimes been of use, but more often it has failed. Its hypodermic

* For a paper discussing the relations of chloral to various mostly unimportant alkaloids, see *Arch. f. Exper. Path. und Therap.*, ix. 440.

use in the algid stage of *cholera*, as recommended by Dr. Hall (*Lancet* May 2, 1874), appears to me of very doubtful value.

The third indication for which chloral has been used is to *relieve pain*. That it will do so when given in very large doses there can be no doubt; but, unless the dose be so large as to be dangerous, my experience of chloral is that it is of little value as an anæsthetic. Its powers in this direction are incomparably less than those of opium, and its habitual use is probably attended with very grave dangers.

Theoretically, chloral might be of use to *reduce temperature*. Its other active properties will probably completely interfere with its use for this purpose in the vast majority of such cases, especially as, in order to check the development of animal heat, the dose must be very large. When, however, there is a high sthenic state of the system, it might be tried with caution; but clinical experience is almost entirely wanting. I know of but a single case (*Med. Times and Gaz.*, Nov. 1869) reported: in this its use is said to have given satisfaction.

Locally a solution of chloral (ten per cent. to saturation) has been used with asserted very good effects as a stimulant and antiseptic in foul ulcers, buboes, bedsores, etc., especially when the discharge is free, as a hæmostatic when there is oozing of blood, and as an antiseptic and local anæsthetic in *uterine* and other *cancers*. Applied to the skin, it is a powerful irritant, and has been proposed as a vesicant, but is said to cause excessive pain. See *New York Med. Journ.*, xxxvii. 445; also *La Medecine Moderne*, July 17, 1890.

Professor Oré, of Bordeaux, has proposed *intravenous injections* of chloral as a substitute for ether and chloroform in surgery, and as a means of combating tetanus. His suggestion has been carried out by himself and others in a number of cases with asserted good results. But in other instances it has apparently caused death, and its use is, in my opinion, absolutely unjustifiable. The risks are twofold. Under any circumstances chloral occasionally acts with unexpected violence, and it has caused death even when exhibited by the mouth in what are usually considered safe doses. It is plain that this danger is vastly increased by throwing the whole dose at once upon the heart and nervous system. Every one who has practised intravenous injections in animals must be aware of the extraordinary results of throwing the poison almost undiluted into the cavities of the heart. Again, chloral exerts a very great influence on fibrin, and has even been used to coagulate the blood in varices; the intravenous use of the drug may, therefore, be productive of thrombi; indeed, M. Tillaux has reported a case in which a venous coagulum was found after death extending up the arm even into the axillary vein, and accompanied by a white heart-clot.*

* Any one desirous of following this subject further will find the following references of value:

Archives Gén., ii., 1874; *Bulletin de l'Acad.*, xxxviii., 1874; *Gaz. Méd.*, xlv., 1874; *Gaz. Méd. de Bordeaux*, xlii., 1874; *Gaz. des Hôpitaux*, 1874; *Le Progrès Méd.*, 1874; *Journal de Thérap.*, 1874; *Presse Méd. Belge*, Oct. 1874.

The antiseptic powers of chloral were apparently first noticed by MM. Dujardin-Beaumetz and Hirne in 1872 (see *Bulletin Thérap.*, lxxxvi. 224). Recently the subject has been investigated by various observers, especially by Dr. Keen (*Phila. Med. Times*, vol. iv.) and M. Personne. It has certainly been shown that a solution of twenty to forty grains to the ounce will preserve animal tissues for a great while, and probably indefinitely. Moreover, the finest microscopical structure appears not to be altered by a solution of this strength. Dr. Keen's first experiences led him to hope that, as chloral does not materially affect the color of the tissues, it might be useful in the dissecting-room, and subsequent trials of it have confirmed Dr. Keen's first hopes (*Amer. Journ. Med. Sci.*, July, 1875). Dr. Keen has also had great satisfaction in the use of chloral to keep free from odor the urinals of paraplegics and other patients suffering from incontinence.

Toxicology.—That chloral is a dangerous agent, capable of destroying life, is attested by a number of published cases; but this is true of other drugs; and the practical point to be determined is, Does it ever act out of proportion to the amount ingested? or, in other words, does the ordinary therapeutic dose ever become toxic, and does it ever act in a cumulative, unexpected manner? Abroad, it has very commonly been prescribed in half-drachm and even drachm doses, and in the vast majority of cases without any bad results. That thirty grains is not a safe dose is shown, however, by the case of Dr. Reynolds (*Practitioner*, March, 1870), in which forty-five grains caused most alarming symptoms; by that of Dr. Watson (*Med. and Surg. Reporter*, Jan. 27, 1871), in which eighty grains, given in ten-grain doses spread over thirty-six hours, nearly proved fatal; and especially by a number of cases recorded by Dr. H. W. Fuller (*Lancet*, March, 1871), in some of which very alarming symptoms followed the exhibition of thirty grains, and in one death in a healthy young woman of thirty. Dr. Schwaighofer, of Vienna, records (*Irish Hosp. Gaz.*, 1873) coma and death in a drunkard following the ingestion of half a drachm. Dr. W. H. Lathrop (*Year-Book of Therapeutics and Pharmacy*, 1872, p. 254) records the case of a man previously healthy, but suffering from delirium tremens, who took sixty grains between 12 and 1 p.m., at 2.30 p.m. twenty grains more, and at 3 p.m., no effect being manifest, twenty grains more. His physicians then left him sleepless and complaining only of a slight paralysis of the lower extremities; and almost in a moment he was dead. Other cases might be quoted (see *Berlin. Klin. Wochenschrift*, 1876), but the above are sufficient to show that chloral may kill suddenly and unexpectedly.

An observation of Professor Vulpian (*Comptes-Rendus*, lxxxvi. 1303) throws much light upon these sudden deaths. He found that galvanization of a divided vagus would cause in a chloralized animal not momentary, but permanent, arrest of respiration, if the centric end was selected, or permanent diastole of the heart if the distal part of

the nerve was attacked. It is very probable that in a man under the influence of chloroform or of chloral, death may be precipitated by a slight peripheral inhibitory irritation. I think the practical deduction from the known facts is that twenty grains is the highest safe dose of chloral; that this amount should not be repeated oftener than once an hour, and, when sixty grains have been taken, not again for some hours, unless in very urgent cases, as acute tetanus or violent chorea threatening speedy dissolution. On the other hand, recovery has been reported by Dr. Eshleman (*Phila. Med. Times*, Oct. 1870) after the ingestion of four hundred and sixty grains. There are no lesions found after death from chloral which can be considered pathognomonic, but a dark, bloated countenance and other evidences of death from asphyxia have been noted in some cases.

The treatment of chloral-poisoning is identical with that of opium-poisoning, consisting in the free use of alcoholic and external stimulants, such as sinapisms, dry heat, frictions, flagellations, etc., to maintain the circulation, and of shaking, walking, application of dry electric brush, cold douches, etc., to keep up the respiration. In practising these measures it must be remembered, however, that the patient in chloral-poisoning is much more apt to die of exhaustion, and especially of cardiac failure, than in opium-poisoning, and that therefore those methods of arousing the nerve-centres which do not, like walking, require the expenditure of effort on the part of the patient are to be preferred. Artificial respiration should always be resorted to before natural respiration altogether fails; and Clemens (*Schmidt's Jahrbücher*, Bd. cli. p. 99) has found that animals asphyxiated by chloral may often be at once aroused by the inhalation of oxygen. Hypodermic injections of strychnine have been recommended on theoretical grounds, and a case is reported by Dr. B. W. Stone (*Louisville Med. News*, xv. 179), in which four hundred and twenty-five grains of chloral were ingested, and recovery occurred after the hypodermic use of one-fifth of a grain of strychnine in divided doses. Atropine seems to me a very rational remedy, and Dr. I. M. Booth reports a case (*Lancet*, 1884, i. 468) of recovery after about one hundred and ten grains of chloral under the use of tincture of belladonna. Probably it will hereafter be found that it is very important in all forms of threatening narcotism to maintain the animal heat. Dr. Lauder Brunton has shown (*Journ. Anat.*, viii., 1874) that if the bodily temperature be maintained artificially animals survive doses of chloral usually fatal, or recover consciousness more quickly than is normal after small doses. The inference is very obvious that in human chloral-poisoning, by the use of dry external heat, hot blankets, hot baths, and other devices, the warmth of the patient should be maintained.

Considerable attention has been given both in this country and abroad to the subject of *chronic chloral-poisoning*; and, while some affections have been erroneously attributed to the drug, there seems

to be no doubt that its long-continued use often does produce serious symptoms. The cases are divisible into two or three groups, which are, however, really artificial, as is shown by the occurrence of cases belonging to two or even three of the groups. The first of these includes those patients in whom the respiration is chiefly affected. The dyspnoea may be slight, and may only be felt at times, as after exertion or after meals; but it may be constant and alarming. Cases of this character are reported by Jastrowitz, by Schule, and by Ludwig Kirn (*Allgem. Zeitschrift für Psychiatrie*, xxix., 1872; *Practitioner*). In one instance (Professor N. R. Smith, *Boston Med. and Surg. Journ.*, 1871) death from bronchial effusion is believed to have been caused by chloral. Dr. Kirn affirms (*Berlin. Klin. Wochenschr.*, xx. 721) that in some cases mental disturbance with hallucinations occurs.

In the second group of cases, eruptions of the skin are the chief manifestations of the toxæmia. In the mildest of these there is no distinct rash, only the occasional appearance of transient red blotches on the face or neck. But a very extraordinary tendency exists towards the production of a rash or discoloration at the slightest cause, so that drinking a glass of wine will produce an intense, even livid, erythematous redness of the face. In other instances there is marked erythema (Schule, *Allgem. Zeitschr. für Psychiatrie*, xxviii.), occurring first in spots upon the face, but extending downwards to the trunk, becoming more and more general, and showing a marked tendency to follow the nerve-trunks. This erythema is seemingly due to vaso-motor weakness, and consequently is allied to other more urgent symptoms seen in chloral toxæmia. Sometimes it invades the mucous membranes, which become red, swollen, and cedematous; and if the glands are involved, as in a case reported by Dr. Chapman (*Lancet*, 1871), the result may be serious. A deeper implication of the vaso-motor and cardiac nervous system was probably the cause of the general oedema, profound weakness, and failure of heart-action in the case recorded by Professor N. R. Smith (*loc. cit.*). Professor Smith also calls attention to desquamation of the cuticle and ulcerations about the nails as being present in these cases.

In the third group of cases, petechiæ, ecchymoses, ulcerations, and even high fever and other pyæmic symptoms, are asserted to have been produced by the continuous use of chloral. It seems to me, however, very doubtful whether the drug really was the cause of the symptoms which have been recorded by Crichton Brown, by Monkton, and by Kirn.

The habitual use of chloral as a narcotic has been indulged in, it is asserted, to a considerable extent, and Dr. George F. Elliott reports (*Lancet*, 1873, i. 754) a case in which "delirium tremens" followed the withdrawal of the accustomed draughts.

ADMINISTRATION.—Sufficient has been said as to the dose of chloral. It is best given diluted with a weak syrup.

METACHLORAL is prepared by acting on chloral hydrate with sulphuric acid. The hard white substance which forms after a few days is washed with water and dried by means of chloride of calcium; then, mixed with gum, it is formed into crayons, which are coated with paraffin, for external use as a counter-irritant and local anæsthetic. It is said to be less irritating than chloral (*Lancet*, i., 1874).

CHLORALAMID.—By the addition of various principles to chloral the German chemists have produced certain compounds having active physiological properties. Among these is *chloralcyanhydrat*, whose action resembles very closely that of prussic acid (Otto Hermes, *Thesis*, Berlin, 1889); *chloralammonium* (chloral and ammonia); *chloralurethane* (chloral and urethane); *chloralformamid* (chloral and formamid). Of these compounds, the last is the only one of practical interest. Under the name of *chloralamid* it has been used as an hypnotic. It is a slightly bitter crystalline substance, soluble in nine parts of water and one and a half parts of strong alcohol. It is decomposed by hot water, but its solution in cold water is moderately permanent; it is rapidly decomposed by alkalis. In the lower animals, chloralamid produces lethargy, narcosis, sleep, and, finally, if it has been taken in sufficient amount, death from failure of respiration. According to Langgaard (*Therap. Monatsch.*, 1889), in the rabbit the sleep is accompanied by pronounced decrease in the amount of air drawn in and out of the lungs, and pronounced lessening of the blood pressure. These results, however, are scarcely in accordance with those of other observers. Otto Halasz (*Wien. Med. Wochensch.*, 1889) found the blood-pressure very slightly affected. Von Mering and Zuntz have shown that the fall in the air movements of respiration obtained by Langgaard were not greater than those which result from sleep; and also obtained deep sleep and even complete anæsthesia in the rabbit without fall of the arterial pressure.

In a series of experiments made by Dr. Cerna and myself in the laboratory of the University, it was found that the influence of chloralamid upon the circulation is very feeble; only the largest toxic dose lowering the arterial pressure at all. In the dog the respirations were always enormously hurried by the drug, although no experiments were made to determine the absolute amount of air moved. The action of the drug upon the spinal cord was also very feeble, and no perceptible influence was shown upon the nerves and muscles; but the effect upon the cerebral cortex was very pronounced.

THERAPEUTICS.—My own experience with chloralamid seems to be in accord with the general verdict, that it is an hypnotic, slower in action and scarcely equal in certainty to chloral; it usually does not cause any unpleasant after-effects, but sometimes produces confusion, giddiness, and headache. It has been especially recommended by Hagemann and Hüfler (*Munch. Med. Wochensch.*, 1889) for the relief of cardiac asthma. Our knowledge of its physiological action seems to show that the

assertions of various clinicians, that it is better borne than chloral in cases where there is cardiac weakness, has a foundation in fact. It should be given in doses of from thirty to fifty grains, administered in watery solution or capsules half an hour before expected time of sleep.

CHLORALOSE.—When anhydrous chloral and glucose are heated together for an hour at the temperature at which chloral boils, two isomeric substances—*chloralose*, which is soluble, and *parachloralose*, which is insoluble—are formed. Chloralose occurs in small crystals, having a very bitter and disagreeable but not acrid taste. It is freely soluble in hot water, slightly so in cold water, a little less than five grammes to the litre. It was first brought forward as a remedial agent by Hanriot and Richet (*Bull. Soc. Biolog.*, 1893), who state that five grammes of it will produce in a dog of ten kilogrammes' weight symptoms of intoxication followed by a most profound sleep in which all sensibility is lost, although the reflex activities are greater than normal. Upon the circulation the drug has but little power, the arterial pressure, even when there is profound unconsciousness, being scarcely affected. During the unconsciousness not only is the motor side of the spinal cord more active than normal, but the cerebral cortex was also found to be excessively excitable, the animals experimented upon offering a strong contrast with chloralized dogs in which the cerebral cortex was almost devoid of responding power. When taken by man in doses of 0.3 gramme, chloralose produces a profound sleep lasting many hours, from which the patient wakes without unpleasant effects. Richet's dose is 0.15 to 0.50 gramme. On account of its excessively bitter taste it should be given in capsules, whose effects are said to develop in about half an hour. Six-tenths of a gramme are said to have produced complete unconsciousness in man, with slight slowing of the pulse and marked congestion of the face (*British Med. Journ.*, ii., 1893), but doses of one gramme have been given in France without any evil results.

CHLORAL CAMPHOR.—Equal parts of chloral and camphor rubbed together produce a clear liquid. Dr. Lenox Browne claims that this "when painted over the painful parts and allowed to dry" gives the greatest relief in *neuralgia*, and that in *toothache* it is equally efficacious. It occasions tingling of the skin, but never blisters, and has been commended in *pruritus*. A drachm of it swallowed by mistake produced very severe prostration, feebleness of the pulse, vomiting, fifteen "coffee-ground" stools, and prolonged narcotism, with brief semi-delirious periods, lasting four days (*Amer. Journ. Med. Sci.*, lxxix. 90). Dr. D. B. Simmons, who reports the case, has since found chloral camphor, in doses of ten to twenty drops, to be very powerful as a sedative narcotic in mania, etc.

BUTYL-CHLORAL HYDRATE.—The substance brought forward as a remedy by Oscar Liebreich under the name of *croton-chloral hydrate* is

formed by the action of chlorine gas upon aldehyde. It crystallizes in small glittering tables,* and is soluble with difficulty in water. It is now stated to be really butyl-chloral, which, when brought in contact with an alkali in solution, breaks up into chloride and formate of sodium, and bichlorallylene. According to Liebreich (*Brit. Med. Journ.*, Dec. 20, 1873, and Feb. 1876), a drachm of this substance, dissolved in water, and introduced into the stomach, produces in the course of from fifteen to twenty minutes a deep sleep, accompanied by anæsthesia of the head. While the eyeball has lost its irritability, and the trigeminal nerve shows no reaction whatever on being irritated, the tone of the muscles remains unaltered. The effect upon the pulse and respiration is also stated to be much less than that produced by equivalent doses of chloral hydrate. Liebreich declares that the symptoms after large doses are deep sleep, trigeminal anæsthesia, and death by arrest of respiration. The circulation, he affirms, is kept up with great tenacity, and, even if cardiac action, as well as respiration, has ceased, artificial respiration is able to restore the action of the heart immediately, and the life of the animal may thus be saved. Immense doses of croton-chloral produce cardiac paralysis. According to the author just quoted, the value of the drug is in its power of lessening sensibility before producing narcosis. These assertions of Liebreich are not borne out by the seemingly much more elaborate researches of J. V. Moring (*Arch. f. Experim. Pathol. Pharm.*, Feb. 1876). He found that the sensibility of the cornea was not abolished until the respiration was reduced to one-half its normal rate. In dogs, cats, and rabbits the blood-pressure was reduced temporarily by small doses, permanently by larger ones. Intravenous injections of sufficient quantity and concentration were followed by immediate arrest of the heart. Altogether, the symptoms caused by croton-chloral seemed exactly parallel with those induced by chloral hydrate. II. Windel Schmidt (*Centralbl. f. Chirurgie*, 1877, p. 210) also found narcosis to precede the anæsthesia of the head. According to E. Külz, butyl-chloral is eliminated as *urobutylchloralic acid*, a substance analogous to *urochloralic acid* (*Arch. f. Gesamte Physiol.*, xxviii. 534).

Croton-chloral has been highly praised by Liebreich for its powers of relieving neuralgias and other painful affections of the trigeminus. He affirms that it will afford relief even in severe *tic-douloureux*, but is, unfortunately, only palliative. His statements have been confirmed by Drs. J. W. Legg (*Lancet*, 1873), Benson Baker (*Brit. Med. Journ.*, Oct. 1873), J. B. Yeo (*Lancet*, Jan. 1874), Sydney Ringer (*Brit. Med. Journ.*, 1874), and F. B. Leo (*Ibid.*). In a single very severe case of centric tic under my own care, ten grains of the drug have given very decided

* For a detailed account of physical and chemical characters, see a paper by E. Schering, *Nenes Repertor. für Pharm.*, Bd. xxi. Heft 5, 1872, which I have abstracted into *New Remedies*, vol. ii.

temporary relief, and compelled sleep. It is usually administered in doses of from five to twenty grains, in syrup. The safest plan is to give five grains every half-hour until thirty grains have been taken or relief afforded. Liebreich uses it according to the following formula: butyl chloral hydrate, 5 to 10 parts; glycerin, 20 parts; distilled water, 130 parts. Dose, half an ounce, followed in five minutes by a second, and ten minutes later by a third unless relief is afforded.

SULPHONAL.

This substance, whose proper chemical name is *diethylsulfondimethylmethan*, was made by E. Baumann in 1886, and first physiologically and clinically reported upon by Professor A. Kast (*Berlin. Klin. Wochenschr.*, 1888). It occurs in thick colorless prisms, soluble in eighteen to twenty parts of boiling water, not soluble in one hundred parts of cold water, slightly soluble in ether, benzol, chloroform; tasteless, odorless, and of very persistent constitution.

PHYSIOLOGICAL ACTION.—The symptoms which are produced in man by even large therapeutic doses of sulphonal are simply quiet sleep, out of which the patient wakes after some hours in his normal condition, or not rarely with a certain amount of giddiness and lack of mental tone. It seems doubtful whether any single dose of sulphonal will cause death in the robust adult; certainly enormous doses have been taken and survived. Thus, in the case reported by E. Neisser (*Schmidt's Jahrb.*, Bd. cexxxi.), a young man took one hundred grammes, which were followed by profound sleep lasting ninety hours, without disturbance of the heart or breathing, but with a symmetrical minutely papulous eruption upon the hands and a fall of the bodily temperature to 96° F., followed by a slight rise. The pupils reacted to light; the corneal reflexes were present. On waking, the patient had marked ataxia of speech and of movement, which had entirely disappeared by the eighth day. On the other hand, there have been a number of cases of fatal poisoning reported as the result of the habitual use of sulphonal. Certainly, in many instances, and probably always, the outbreak of symptoms is preceded by a red coloration of the urine, which deepens until the fluid becomes of a dark-red color, staining the linen upon which it falls red. Usually this coloration of the urine is soon followed by obstinate constipation, with violent vomiting, spasm of the abdominal muscles, with tenderness upon pressure in the region of the liver and stomach. At the same time nervous symptoms develop, irregularity of gait, ataxia, suppression of perspiration, paresis of the upper extremities or perchance paresis of irregular groups of muscles, pronounced weakness of the legs, with loss of the patella reflex, paræsthesia, muscular spasms, and finally a condition of profound collapse, with albuminous, hemorrhagic, or suppressed urine, and death. In the frog, the dog, and the rabbit sulphonal produces sleep, which, if the dose be sufficiently large, deepens into coma, and is accompanied by

paresis, tremors, and convulsions. Knoblauch affirms that not infrequently the loss of power in the hind legs precedes sleep, and that weakness and ataxia are prominent symptoms after large doses. The convulsions, which are said to be epileptic, are only produced by very large toxic doses. Professor Kast says that the blood-pressure is not altered by doses which produce sleep, and in the experiments of Shiek there was even pronounced rise of the arterial pressure, the cause of which was not determined; as no experiments were made upon the curarized animals, the rise in the blood pressure may have been produced by the failure of respiration. Shiek states that the drug has no influence upon the motor or sensory nerves, nor upon the muscles.

The reflex activity is markedly diminished in the frog as in man by sulphonal, which is probably a direct depressant to the spinal cord; but Shiek states that in some of his experiments the reflex activity was increased, and that the decline of the reflexes is in fact due to stimulation of the Setschenow's centre. Further experiments are necessary before positive conclusions can be reached. Kast found that there is neither microscopic nor spectroscopic blood changes in animals acutely poisoned by the drug. The drift of the present evidence indicates that sulphonal has no distinct effect upon tissue change, but the matter is still entirely *sub judice*.* Gritzka claims increase of carbonic acid elimination (*Inaug. Diss.*, Berlin, 1891). When taken in large amount, sulphonal escapes in part from the kidneys unchanged, but the greater portion of it appears to be eliminated in the form of an organic sulphur compound. According to the researches of W. J. Smith (confirmed by Baumann and Salkowski, *Centralb. f. d. Med. Wissen.*, xxx., 1892), this is probably *ethyl sulphonic acid*.

THERAPEUTIC USE.—Sulphonal is a powerful hypnotic, having, however, little or no analgesic effects, and ranking next below chloral in power and certainty of action. Sleep usually develops in from half to one hour after the dose, in most cases gradually, but sometimes with abruptness. It is usually quiet, and not followed by any disagreeable after-effects, although sometimes mental confusion and lassitude remain during the following day; these after-results being, in my experiments, especially apt to occur in cases in which there is a distinct depression of the brain-nutrition. Where the sleeplessness is due to pain, sulphonal is usually not serviceable; but in the insomnia of insanity it generally acts well. Later experience, however, does not seem to carry out the original assertion of Professor Kast, that sulphonal is especially useful in cases of insomnia from cardiac diseases. In such affections it appears

* The most important papers are those of Dr. W. J. Smith (*London Pract.*, 1899 and 1901) and Martin Hahn (*Virehne's Archiv*, Bd. cxiv.). Professor John Gordon (*British M-J. Journ.*, vol. i., 1893) has found that in weak solution sulphonal and urethan retard slightly the action of pancreatin solution upon starch, strong solutions of the drug having no effect; that chloroform, antifebrin, and antipyrin are without such power; but that paraldehyde, whether in weak or strong solution, had a very profound effect.

to be not only an uncertain, but even a dangerous drug, inferior to chloral (see Joachim. *Therap. Monatsh.*, vol. iii.; also, Schmeij, *Ibid.*, vol. ii., 1888). At present this disagreeable action of the drug does not seem to be explainable by any influence exerted upon the heart. It is possible that it is due to irritation of already congested kidneys.

The action of sulphonal upon the reflexes would indicate its employment in spasmodic diseases, and it has been used with asserted good results in *epilepsy*, *hiccough*, *chorea*, and *nocturnal cramps*, and, according to Professor E. Andrews (*Journ. Med. Assoc.*, 1892), it is very effective against the spasm of fractures. It has also been commended as a sexual sedative in *chordee* and *spermatorrhœa*. In my own practice, sulphonal given an hour after meals has seemed to have value as an intestinal antiseptic. It is claimed that sulphonal is a very useful remedy in *colliquative night-sweats*.

TOXICOLOGY.—Occasionally even the single dose of sulphonal produces nausea (even severe gastric pain: Dauthville, *Paris Thesis*, 1889), languor, headache, depression, or pronounced mental disturbance; and Dr. Bornemann reports a case in which it caused double vision, with the feeling of having two heads and two pairs of arms (*Deutsch. Med. Zeitung*, 1888). Then, again, in rare cases sulphonal produces much excitement. An important fact is that a chronic poisoning usually develops with apparent rapidity, and, notwithstanding the suspension of the remedy, goes on steadily, though it may be slowly, to a fatal issue. It has been shown by Salkowski (confirmed by Kast, *Archiv. f. Exper. Path.*, 1892, Bd. xxxi.) that æthyl-sulphonic acid is not poisonous, and hæmatoporphyrin appears also to be free from poisonous properties; so that the symptoms of chronic poisoning are probably due to an accumulation of sulphonal in the system, and are of largely primary and not secondary character, though some of them may be in fact uræmic. The appearance of hæmatoporphyrin, a decomposition product of hæmatin, in the urine indicates a destruction of the red blood-corpuscles, and there have been found after death marked evidences of nephritis. The experiments of Kast (*loc. cit.*) would indicate that an early, if not the first, renal lesion is hemorrhage within the glomerules. The exanthem of sulphonal-poisoning is usually a minutely papulous eruption, which has been described by some as resembling that of measles, by others as like that of scarlet fever. It is not rarely symmetrical, and often shows a disposition to follow the nerve-trunks, so that it is probably neurotic. The early recognition of hæmatoporphyrin in the urine is best made by means of the spectroscope.

There is no specific treatment for sulphonal-poisoning. Great good has seemed in some cases to have been produced by the free use of warm water, which should be given as largely as can be taken by the mouth, and also by injections into the rectum, with the hope of flushing the kidneys and aiding them in the throwing off of the poison.

ADMINISTRATION.—The dose of sulphonal is from ten to forty-five

grains. It is absorbed with difficulty, and it should always be administered in fine powder diffused in water or milk, or enclosed in capsules. I have seen compressed pills of sulphonal pass through the body unchanged, and have no doubt that the reported great slowness or even failure of action has often depended on improper method of administration. It should be an invariable rule when sulphonal is given continuously every two weeks to suspend its employment for some days, so as to allow the system to clear itself; and the urine should also always be carefully watched and the first appearance of the red tint be the signal for immediate withdrawal.

Closely allied chemically to sulphonal are two compounds known, respectively, as *Trional* and *Tetronal*. Each occurs in the form of brilliant scales of a bitter taste, with an odor like that of camphor. Neither of them is soluble to any extent in water. They have been used as hypnotics, and probably resemble in their physiological action sulphonal, although we have no very definite conclusion in regard to this. According to Dr. Koppers, trional is also an excellent antihydrotic in colliquative *night-sweats*. They have been used especially in insomnia due to mental excitement, trional being apparently generally preferred. The dose is from fifteen to twenty grains, best administered in milk just before retiring, as the soporific effects come on promptly. It has been claimed that no evil effects follow the prolonged use of these drugs, but I have seen excessive prostration apparently produced by the continuous exhibition of trional.

PARALDEHYDUM—PARALDEHYDE. U.S.

Acetic aldehyde is obtained by the action of an oxidizing agent, as chromic acid, upon alcohol. The aldehydes are various, chloral itself being trichloraldehyde, but acetic aldehyde is the one usually known simply by the name of aldehyde. It exists in two polymeric modifications,—one being paraldehyde and the other metaldehyde. Paraldehyde may be prepared by heating acetic aldehyde with a small quantity of hydrochloric acid or with zinc chloride. Its formula is $(C_2H_4O)_3$ or $C_6H_{12}O_6$, which latter represents the addition (combination) of the three molecules represented in the first formula. It is a colorless liquid, having a boiling-point of $123.5^\circ C.$, and a very disagreeable odor and taste. *Metaldehyde* may be prepared by passing gaseous hydrochloric acid through acetic aldehyde and then cooling with a freezing mixture. It crystallizes in needles or tetragonal prisms.

PHYSIOLOGICAL ACTION.—The physiological action of paraldehyde was first investigated by Dr. Cervello (*Archiv f. Exper. Path. Pharm.*, xvi. 265), whose results have been confirmed and extended by Albertoni (*Arch. Ital. de Biol.*), Quinquad (*Compt.-Rend. Soc. Biolog.*, 1884), Henocque (*Ibid.*), Vulpian (*Ibid.*), Bochesontaine (*Ibid.*), Prevost (*Internat. Congress*, 1884, vol. i.), John Gordon (*Brit. Med. Journ.*, i., 1889), and L. Coudray (*Compt.-Rend. Hôp. Cochin Lab. Therap.*, 1884-89). In frogs

it produces sleep, with loss of sensibility and complete relaxation of the muscular system, without affecting the cardiac movements or the vagi or motor nerves. After toxic doses death occurs from paralysis of the respiratory centre. In the rabbit doses of thirty-five to forty-five grains cause profound sleep, with progressively diminishing respiration, and at last death from asphyxia, without convulsions. Enormous doses of paraldehyde may be taken by man without a fatal effect; thus, in a case reported by Dr. Mackenzie (*Brit. Med. Journ.*, 1891, ii.), three and a half ounces caused deep unconsciousness, with vomiting, imperceptible pulse, stertorous respiration, and collapse, but recovery occurred in forty-one hours. Chronic poisoning by the drug seems rare; in Goodman's case, a woman who took habitually eighteen ounces in twenty-four hours recovered in six weeks. According to the researches of Gordon, not only the cerebral but also the whole lower nervous system is affected by the toxic dose of paraldehyde, the excitability of the spinal cord and the irritability of motor and sensory nerve-trunks, and also of the muscle itself, being diminished. The influence of paraldehyde upon the circulation is not pronounced, but some slowing of the pulse has been noted, and Gordon, Coudray, and Quinquad have found that very large doses lower the arterial pressure and lessen the heart's force. Paraldehyde is eliminated with the urine, to which it imparts its odor; and, according to Gordon, it increases the excretion of urea, although it usually diminishes rather than increases the flow of urine.* The fall of bodily temperature in poisoning by it is accompanied by lessened elimination of carbonic acid and change in the blood color, which latter, according to Quinquad, is due to the formation of methæmoglobin, but according to Henocque, to reduced hæmoglobin, whilst Dr. Coudray appears to differ from both of these investigators.

THERAPEUTIC PROPERTIES.—Paraldehyde is a somewhat uncertain hypnotic, which has little influence over pain, but which has been used to a considerable extent in doses of one drachm, well diluted. Its exceedingly nauseous taste, and the disagreeable odor which it is apt to impart to the breath, as well as its tendency to disturb the stomach, have prevented it from being much employed. Dr. J. G. Kiernan has found its prolonged use to be followed by intractable nasal ulcers, skin-eruptions, and other evidences of disturbance of nutrition, such as occur after the similar employment of chloral; Dr. Sommer (*Neurol. Centralb.*, 1886) has noted severe vaso-motor disturbance, and Kraft-Ebing has seen delirium and other outward results, and also a paraldehyde habit. Dr. H. B. Williams (*Journ. Amer. Med. Assoc.*, vol. viii.) states that he has used it with success in *epilepsy*. Professor Bokai (*Pharm. Post*, April, 1886) found it in animals the physiological antidote of strychnine; and Kraft-Ebing used it successfully, in doses of three drachms a day, in *spinal accessory spasm* (*Zeitschr. f. Therap.*, April, 1887).

* According to Chittenden and Stewart (*Stud. Physiol. Chem.*, Yale, iii.), paraldehyde inhibits amylolytic, but increases the activity of proteolytic ferments.

AMYLENE HYDRATE is a clear, colorless liquid, of a penetrating odor, soluble in eight parts of water, and miscible with alcohol in almost all proportions, whose physiological properties were discovered in 1885 by Von Mering and Thierfelder (*Zeitschr. f. Phys. Chemie.*, Bd. 1. 8. 9. According to Von Mering, it is a valuable hypnotic, standing midway between chloral hydrate and paraldehyde, one drachm of chloral, two drachms of amylene hydrate, and three drachms of paraldehyde being about equivalent in power. In moderate doses it is said to produce in the lower animals deep sleep without affecting the respiration or circulation. Large doses paralyze the medulla oblongata. Dr. C. Dietz (*Deutsch. Med. Zeitung*, 1888) reports cases in which over-doses, believed to be five grammes of amylene, were taken by mistake. About twelve hours later the patients were found deeply narcotized, with extremities paralyzed, pupils dilated, corneal reflexes abolished, respiration very slow, deep, irregular; pulse small, slow, and the temperature distinctly depressed. This condition lasted for some hours, but was recovered from, without treatment except in one case in which artificial respiration was practised for ten minutes. The physiological action of amylene has been investigated especially by Erich Harnack and Hermann Meyer (*Fortschritte der Medicin*, xi., 1893). It produced in the lower animals deep sleep, with, if the dose were sufficient, great fall of animal temperature, which is believed by the experimenters to have been due to excessive loss of heat. The circulation was very little affected by the drug, though finally it reduced pressure by dilatation of the blood-paths. When in sufficient amount it acts both upon the voluntary and the cardiac muscles as a poison, first increasing and then paralyzing functional power. In conformity with results obtained by Peiser upon man, Harnack found that in animals it markedly decreases the elimination of urea.*

Recent reports (see especially *Berlin. Klin. Wochens.*, 1888) seem to show that amylene is a safe and useful hypnotic, superior to paraldehyde, but less certain than chloral and sulphonal. Dose, thirty to forty minims.

URETHAN is chemically carbamate of ethylic ether. It occurs in crystals or crystalline masses, without odor, and having a taste like salt-petre. It is soluble in one part of water, six-tenths parts of alcohol, one part of ether, one and three-tenths parts of chloroform, and three-tenths part of glycerin. The watery solution has a neutral reaction. Attention was first called to it as a possible hypnotic by Professor Schmiedeberg (*Archiv f. Exper. Path. Pharm.*, xx. 210), and it has since been physiologically investigated by Jacksch (*Wien. Med. Blätter*, 1885), by Professor Von Anrep (*London Med. Rec.*, December 15, 1886),

* Harnack and Meyer found that when given hypodermically the hydrate produced great increase in the urea elimination through the violent local inflammation which it set up.

and by Dr. Paul Binot (*Rev. Med. de la Suisse Rom.*, September, 1893). When urethan is given to one of the lower animals it produces first a period of excitement, with increased respiration and cardiac movements, which is followed very shortly by a deep sleep, with slowing of the respiration. If a fatal dose has been taken, the respiration becomes slower and slower, the unconsciousness absolute, the reflexes are abolished, and a pronounced fall of the bodily temperature occurs, with marked weakness of the cardiac action, and finally death from asphyxia. According to Schmiedeberg, the action of urethan upon the circulation is very slight, much less than that of chloral; even in deep narcosis the arterial pressure remaining normal. The lessening of reflex activity is primarily due to an action upon the spinal cord, although the irritability of the peripheral endings of the motor nerves is said to be lessened. The psycho-motor centres in the cerebral cortex, according to Von Anrep, suffer decrease of their faradic excitability under the influence of decided doses. Urethan is an uncertain hypnotic, which, however, acts well in some cases. It has been used hypodermically by Koenig in doses of as high as twenty-one grains without success. By the mouth, according to Kraepelin, a full dose is forty-five grains, but seventy-five grains may be given. It appears to have no analgesic effect. It has been given by Jackman (*Lancet*, June, 1886) in traumatic tetanus with success after the failure of chloral (a boy aged fifteen, four grains every two hours); and by Dr. T. S. Bennett with asserted advantage in the eclampsia of childhood and of the puerperal state (*Trans. Texas State Med. Assoc.*, 1887).

HYPNONE, OR ACETOPHENONE, is a colorless, volatile liquid, having a very tenacious, persistent odor, recalling that of bitter almonds, not inflammable, not soluble in water or in glycerin, but very soluble in alcohol, ether, chloroform, benzin, and also certain oils, especially that of sweet almonds. It was first proposed as a hypnotic by Dr. Dujardin-Beaumont, who states that in the lower animals it causes deep sleep. M. Laborde (*Compt.-Rend. Soc. Biol.*, 1885) affirms, however, that it does not produce in the lower animals deep sleep unless given in toxic doses, when the unconsciousness terminates in death from asphyxia. He also states that it has a powerful local paralyzant influence. Professor Grassot (*Semaine Med.*, Dec. 1885) likewise failed to obtain a hypnotic influence, either by hypodermic or stomacheic administration, in dogs and monkeys, and Mairat and Combemale (*Montpellier Méd.*, vol. xviii., 1886) also find that its narcotic power varies in different animals, and that the paralytic is usually greater than the soporific influence. After fatal doses, coma, general muscular paralysis, and death from asphyxia result. The reports of clinicians upon the action of hypnone generally condemn it. Kraepelin, it is true, speaks of it as a useful remedy, and Dr. C. Norman (*Journ. Ment. Sci.*, vol. xxxii. p. 519) has successfully used it hypodermically, in doses of five to twelve minims, in various cases of

insanity; but Hirt, Mairet and Combemale, Rey, and Rottenbiller have all failed to obtain good results from it. The maximum dose given by Rey without success was sixty drops, or twenty-three grains.

METHYLAL is a highly volatile fluid, boiling at 107.60, soluble in water, alcohol, and oil. Prepared chemically by Malaguti in 1839, it was not suggested as a medicine until 1887, when M. Personali discovered that it causes in the lower animals sleep, with increase of the pulse-rate and lowered arterial pressure and temperature. It has been further studied by Dr. M. Motrokhin (*Vratch*, x., 1887, abstracted *Brit. Med. Journ.*, vol. i., 1887), who finds that it lessens reflex activity and the irritability of the cerebral cortex, and when inhaled by man in doses of two ounces produces sleep, with loss of sensibility, without any effect upon the heart. But Dr. Serges Popoff (*Ibid.*) states that according to his researches it acts directly upon the cardiac muscle or its ganglia, both in frogs and in warm-blooded animals. It is rapidly absorbed and very rapidly eliminated, and ought perhaps to be considered as an anæsthetic rather than a hypnotic. It has been given hypodermically, but Motrokhin affirms that its subcutaneous injection is very painful and often causes local gangrene. Mairet and Combemale (*Compt.-Rend.*, Jan. and April, 1887) have used methylal in thirty-six cases of insanity. Their commencing dose is seventy-five grains, their maximum dose one hundred and twenty grains. Its use is said to be free from danger and to cause no unpleasant after-effect; but most patients become rapidly accustomed to it, so that its sleep-producing power is greatly impaired.

FAMILY IV.—DELIRIFACIENTS.

In the present group are considered medicines whose preparations, when taken into the system, cause marked dilatation of the pupil, and act upon the cerebral nerve-cells so as to produce delirium.

EXTRACTUM CANNABIS INDICÆ—EXTRACT OF INDIAN CANNABIS. U.S.

The alcoholic extract of Indian hemp is a blackish, resinous extract, of a decided narcotic odor and a peculiar taste. In the East, hemp and its educts are used as narcotic stimulants. *Ganyah* is the dried plant as sold in the bazaars of Calcutta for smoking. *Churru* is the resinous exudation with the epidermis, etc., scraped off the leaves. *Hashish* is an Arabian preparation of the drug. The resin, which represents the activity of hemp, is sometimes known as *Cannabine*. It is best obtained by precipitating the saturated tincture with water containing an alkali. Hemp also contains a trace of volatile oil.

PHYSIOLOGICAL ACTION.—When given in full doses, *cannabis indica* produces a feeling of exhilaration, with a condition of reverie, and a train of mental and nervous phenomena which varies very much according to the temperament or idiosyncrasies of the subject, and very probably also, to some extent, according to the nature of his surroundings. The sensations are generally spoken of as very pleasurable; often beautiful visions float before the eyes, and a sense of ecstasy fills the whole being; sometimes the venereal appetites are greatly excited; sometimes loud laughter, constant giggling, and other indications of mirth are present. Some years since, in experimenting with an extract made from the American plant, I took a large dose, and described the result as follows (*Proceed. Amer. Philosoph. Soc.*, 1869, vol. xi. p. 226):

"About half-past four P.M., September 23, I took most of the extract. No immediate symptoms were produced. About seven P.M. a professional call was requested, and, forgetting all about the hemp, I went out and saw my patient. While writing the prescription, I became perfectly oblivious to surrounding objects, but went on writing, without any check to or deviation from the ordinary series of mental acts connected with the process, at least that I am aware of. When the recipe was finished, I suddenly recollected where I was, and, look-

ing up, saw my patient sitting quietly before me. The conviction was irresistible that I had sat thus many minutes, perhaps hours, and directly the idea fastened itself that the hemp had commenced to act, and had thrown me into a trance-like state of considerable duration, during which I had been stupidly sitting before my wondering patient. I hastily arose and apologized for remaining so long, but was assured I had only been a very few minutes. About seven and a half P.M. I returned home. I was by this time quite excited, and the feeling of hilarity now rapidly increased. It was not a sensuous feeling, in the ordinary meaning of the term; it was not merely an intellectual excitation; it was a sort of *bien-être*,—the very opposite to *malaise*. It did not come from without; it was not connected with any passion or sense. It was simply a feeling of inner joyousness; the heart seemed buoyant beyond all trouble; the whole system felt as though all sense of fatigue were forever banished; the mind gladly ran riot, free constantly to leap from one idea to another, apparently unbound from its ordinary laws. I was disposed to laugh; to make comic gestures; one very frequently recurrent fancy was to imitate with the arms the motions of a fiddler, and with the lips the tune he was supposed to be playing. There was nothing like wild delirium, nor any hallucinations that I remember. At no time had I any visions, or at least any that I can now call to mind; but a person who was with me at that time states that once I raised my head and exclaimed, 'Oh, the mountains! the mountains!' While I was performing the various antics already alluded to, I knew very well I was acting exceedingly foolishly, but could not control myself. I think it was about eight o'clock when I began to have a feeling of numbness in my limbs, also a sense of general uneasiness and unrest, and a fear lest I had taken an overdose. I now constantly walked about the house; my skin to myself was warm, in fact my whole surface felt flushed; my mouth and throat were very dry; my legs put on a strange, foreign feeling, as though they were not a part of my body. I counted my pulse and found it one hundred and twenty, quite full and strong. A foreboding, an undefined, horrible fear, as of impending death, now commenced to creep over me; in haste I sent for medical aid. The curious sensations in my limbs increased. My legs felt as though they were waxen pillars beneath me. I remember feeling them with my hand and finding them, as I thought at least, very firm, the muscles all in a state of tonic contraction. About eight o'clock I began to have marked 'spells,'—periods when all connection seemed to be severed between the external world and myself. I might be said to have been unconscious during these times, in so far that I was oblivious to all external objects, but on coming out of one it was not a blank, dreamless void upon which I looked back, a mere empty space, but rather a period of active but aimless life. I do not think there was any connected thought in them, they seemed simply wild reveries, without any binding cord,—each a mere chaos of disjointed ideas. The

mind seemed freed from all its ordinary laws of association, so that it passed from idea to idea, as it were, perfectly at random. The duration of these spells to me was very great, although they really lasted but from a few seconds to a minute or two. Indeed, I now entirely lost my power of measuring time. Seconds were hours; minutes were days; hours were infinite. Still, I was perfectly conscious during the intermissions between the paroxysms. I would look at my watch, and then after an hour or two, as I thought, would look again and find that scarcely five minutes had elapsed. I would gaze at its face in deep disgust, the minute-hand seemingly motionless, as though graven in the face itself; the laggard second-hand moving slowly, so slowly. It appeared a hopeless task to watch during its whole infinite round of a minute, and always would I give up in despair before the sixty seconds had elapsed. Occasionally, when my mind was most lucid, there was in it a sort of duplex action in regard to the duration of time. I would think to myself, It has been so long since a certain event,—an hour, for example, since the doctor came; and then reason would say, No, it has been only a few minutes; your thoughts or feelings are caused by the hemp. Nevertheless, I was not able to shake off this sense of the almost indefinite prolongation of time, even for a minute. The paroxysms already alluded to were not accompanied with muscular relaxation. About a quarter before nine o'clock, I was standing at the door, anxiously watching for the doctor, and when the spells would come on I would remain standing, leaning slightly, perhaps, against the door-way. After a while I saw a man approaching, whom I took to be the doctor. The sounds of his steps told me he was walking very rapidly, and he was under a gas-lamp, not more than one-fourth of a square distant, yet he appeared a vast distance away, and a corresponding time approaching. This was the only occasion on which I noticed an exaggeration of distance; in the room it was not perceptible. My extremities now began to grow cold, and I went into the house. I do not remember further, until I was aroused by the doctor shaking or calling me. Then intellection seemed pretty good. I narrated what I had done and suffered, and told the doctor my opinion was that an emetic was indicated, both to remove any of the extract still remaining in my stomach, and also to arouse the nervous system. I further suggested our going into the office, as more suitable than the parlor, where we then were. There was at this time a very marked sense of numbness in my limbs, and what the doctor said was a hard pinch produced no pain. When I attempted to walk up-stairs, my legs seemed as though their lower halves were made of lead. After this there were no new symptoms, only an intensifying of those already mentioned. The periods of unconsciousness became at once longer and more frequent, and during their absence intellection was more imperfect, although when thoroughly roused I thought I reasoned and judged clearly. The oppressive feeling of impending death became more intense. It was horrible. Each

paroxysm would seem to have been the longest I had suffered; as I came out of it, a voice seemed constantly saying, 'You are getting worse; your paroxysms are growing longer and deeper; they will overmaster you; you will die.' A sense of personal antagonism between my will-power and myself, as affected by the drug, grew very strong. I felt as though my only chance was to struggle against these paroxysms,—that I must constantly arouse myself by an effort of will; and that effort was made with infinite toil and pain. I felt as if some evil spirit had control of the whole of me except the will-power, and was in determined conflict with that, the last citadel of my being. I have never experienced anything like the fearful sense of almost hopeless anguish and utter weariness which was upon me. Once or twice during a paroxysm I had what might be called nightmare sensations: I felt myself mounting upwards, expanding, dilating, dissolving into the wide confines of space, overwhelmed by a horrible, rending, unutterable despair. Then, with tremendous effort, I seemed to shake this off, and to start up with the shuddering thought, Next time you will not be able to throw this off, and what then? Under the influence of an emetic I vomited freely, without nausea, and without much relief. About midnight, at the suggestion of the doctors, I went up-stairs to bed. My legs and feet seemed so heavy I could scarcely move them, and it was as much as I could do to walk with help. I have no recollection whatever of being undressed, but am told I went immediately to sleep. When I awoke, early in the morning, my mind was at first clear, but in a few minutes the paroxysms, similar to those of the evening, came on again, and recurred at more or less brief intervals until late in the afternoon. All of the day there was marked anaesthesia of the skin. At no time were there any aphrodisiac feelings produced. There was a marked increase of the urinary secretion. There were no after-effects, such as nausea, headache, or constipation of the bowels."

The sense of prolongation of time which I experienced was to me very remarkable, but is not uncommon in these cases. It is evidently due to the immense rapidity of the succession of ideas. The mind, without doubt, measures time by the duration of its own processes, and when an infinitude of ideas arise before it in the time usually occupied by a few, time becomes infinitely prolonged to the mind. It is a lifetime in the minute. A very common mental phenomenon, not yet mentioned, is a condition of double consciousness, a sense of having two existences, of being at the same time one's self and somebody else.

In some cases Indian hemp produces, in addition to or even in the place of the symptom already spoken of, marked disturbances of motility. Convulsions have been noticed by Dr. Lawrie (*Stille's Therapeutics*, vol. i. p. 772), and local spasms, with salaam convulsions, by Dr. F. H. Brown. According to Dr. O'Shaughnessy, the induction of catalepsy is not rare among the Hindoos.

Whatever may be the symptoms of the first stage, sooner or later,

if the dose be sufficient, drowsiness comes on. Generally, before it is marked, partial anaesthesia, often with partial loss of strength, is manifested, especially in the lower limbs. The pupils are dilated, the pulse is quickened, and finally the subject falls into a heavy sleep, out of which he generally awakes hungry, without any of the wretched gastric sensations or the malaise felt after an opiate. Confusion of thought, however, may persist for some hours. Cannabis exerts no constipating influence upon the bowels, and appears to increase, rather than decrease, the excretion of the kidneys.

In the lower animals cannabis indica produces symptoms somewhat similar to those which it causes in man. In the dog there is a stage of exaltation followed by profound sleep (Hans Zeitler, *Inaug. Diss.*, 1885; H. A. Hare, *Therap. Gazette*, 1887). That the drug has very little influence upon the vital functions is shown by the enormous amounts required in Dr. Hare's experiments to kill. Dr. Hare noted both in the dog and in the frog that there was a period of heightened followed by one of markedly lessened reflex activity. The loss of reflex activity was the result of an influence exerted upon the sensory side of the cord or upon the sensory nerve trunk, the anaesthesia in the frog being complete at a time when voluntary movement was preserved: further, when the drug was applied directly to the nerve-trunk it produced sensory palsy. Although probably a local anaesthetic, cannabis indica is too irritant to be applied to delicate mucous membranes.

THERAPEUTICS.—Leaving out of sight the employment of the medicine by alienists, hemp has been used in this country chiefly for the relief of pain, but also to some extent as a hypnotic. As an analgesic, it is very much inferior to opium, but may be tried when the latter is for any reason contra-indicated. In full doses, in neuralgic pains, it certainly often gives relief. It has been very largely employed to induce euthanasia in the advanced stages of *phthisis*, and constitutes, it is said, a popular nostrum employed for that purpose. In *tetanus*, Indian hemp has been used quite largely, and until within a short time was, after opium, one of the few known drugs of service. Dr. Roemer (*St. Louis Medical and Surgical Journal*, p. 363, 1873) has collected thirty-five cases, with twenty-one recoveries and fourteen deaths. As suggested by Dr. Seguin, of New York, cannabis indica is sometimes of value in the treatment of *migraine*. It should be given continuously, day after day, for months, in such doses as will keep just within the limit of distinct physiological effects.

ADMINISTRATION.—The action of the preparations of Indian hemp is exceedingly variable, in some cases small doses producing alarming effects, in other instances the remedy seeming almost entirely powerless. There appears to be a very great difference in the susceptibility of persons to its influence; but this cannot explain the wide variance of the clinical results obtained by its use. A large proportion of the extracts upon the market must be inert. Possibly the crude drug

undergoes deterioration during its long sea-voyage from India; at least I have had extract carefully made from genuine Indian hemp and offering all the physical characters of good extract, yet entirely inert in doses of many grains. I have seen an eighth of a grain of an English extract produce in a susceptible woman decided intoxication. So far as my present knowledge goes, although the foreign extracts of hemp are often inefficient, they are much more reliable than the American. The only way of administering hemp with satisfaction at present is for the practitioner to try various samples until he gets an active one, and then, being supplied with this, and having learned its proper dose by clinical experiment, to depend solely upon it. Hemp is not a dangerous drug; even the largest doses of its active preparations, although causing most alarming symptoms, do not compromise life. No case of acute poisoning by it terminating fatally has, that I am aware of, been reported. The dose of the officinal tincture (*Tinctura Cannabis Indicæ*—15 per cent., U.S.) is thirty minims; of the fluid extract (*Extractum Cannabis Indicæ Fluidum*, U.S.) one minim; of the extract (*Extractum Cannabis Indicæ*, U.S.) one-sixth to one-fourth of a grain.

Under the name of *tannate of cannabene* the German chemist Merck has put upon the market a preparation of cannabis, which is affirmed by Fronmüller (*Memorabilien*, 1882, 257) and by Hiller (*Berlin. Klin. Wochenschr.*, 1883, ix. 125) to be a very valuable mild hypnotic in doses of from four to seven grains. Fronmüller believes that the failure of others to obtain similar results is largely due to the use of insufficient doses. In some trials which I made of it it seemed to be entirely inert.

BELLADONNÆ FOLIA—BELLADONNA LEAF. U.S.
BELLADONNÆ RADIX—BELLADONNA ROOT. U.S.

The leaves and root of *Atropa Belladonna*, an herbaceous perennial, a native of Europe, but cultivated in this country, and attaining a height of some three feet. The oval, pointed, entire, smooth, unequal leaves are in pairs, on a short footstalk. The bell-shaped, axillary, pendent flowers are of a dull reddish color. The globular berry is about three-quarters of an inch in diameter, deep purple, with a violet-colored juice and adherent green calyx. The dried leaves have a faint narcotic odor, and a sweetish, sub-acrid, slightly nauseous taste. The dried cylindrical branched root is from one to several inches in diameter, much longer, fibrous, externally reddish brown, internally whitish, almost odorless, with a very feeble sweetish taste.

ATROPINA. U.S.

The sole active principle of belladonna, discovered by Mein in 1831 and independently by Geiger and Hesse in 1833, occurs in silky prismatic and acicular, often aggregated, crystals, of a bitter, burning taste,

without odor, soluble in three hundred parts of cold and fifty-eight of boiling water, forty of benzole, thirty of ether, three of chloroform, and eight of alcohol. It is most abundant in the root, and, according to M. Lefort (*L'Union Med.*, Nov. 1871), in that of young plants.* Cyanogen gas passed through its alcoholic solution colors the solution deep red (Hinterboyer). The most reliable test is the physiological one,—i.e., the production of mydriasis in a rabbit or a cat by the local application to the eye. It has been found in all the tissues of poisoned individuals, but always exists in greatest abundance, and is most easily demonstrated, in the urine.†

PHYSIOLOGICAL ACTION.—When the smallest physiological dose of atropine is administered to man, the only symptom induced is dryness of the throat and mouth, and possibly some disorder of vision. When a little larger amount is given, this dryness is more intense, and is associated with redness of the fauces, dilated pupils, disordered vision, and possibly diplopia. The pulse is sometimes at first rendered less frequent, but this decrease is very transient, and certainly in many cases cannot be demonstrated at all. Often from the first, certainly after a short time in all cases, the heart's beats, after a toxic dose of the alkaloid, become excessively rapid, the pulse rising to one hundred and twenty, or even one hundred and sixty; and in a little while a peculiar bright-red flush appears on the face and neck, and may spread over the whole body. As I have seen this, it lacks the punctations of the rash of scarlet fever, and is only in very severe cases followed by desquamation.

Early in the course of the symptoms of atropine-poisoning there is very often forcible expulsion of urine, and erections of the penis may occur; but afterwards there is very generally, Harley says always (*Old Vegetable Neurotics*, p. 207), retention of urine. With the symptoms above enumerated, intellection may remain perfect; but there is generally some lightness of head, giddiness, and confusion of thought, as well as a staggering gait and restlessness. Occasionally, even with doses which may be called medicinal, there are spectral illusions. Drowsiness is not a general or at all characteristic symptom: if present, it is apparently always produced indirectly, as by the removal of some cause of previous wakefulness. When a decidedly poisonous amount of belladonna or its alkaloid has been taken, all the symptoms already noted are intensified, and to them is added a peculiar talkative, wakeful delirium, in which the patient lives in a world of his own, engrossed by the spectres and visions which throng him, and com-

* The most recent chemical researches seem to show that there are three mydriatic alkaloids,—atropine, hyoscyamine, and hyoscyne, daturine and duboisine being mixtures of these. It is also stated that sometimes belladonna root yields only hyoscyamine, and that it is possible to change by chemical treatment some, if not all, of these alkaloids into others.

† For a chemico-physiological study of *tropane* and other derivatives from atropine, see *Archiv. f. Exper. Pathol. u. Pharm.*, v. 403.

pletely oblivious to the surrounding realities. Thus, I have seen a lady remain for a long time stooping and holding fast to the bed-post, to which she talked in the most voluble manner, as though it were an intelligent living entity. Sometimes this delirium is wild, and the patient almost uncontrollably violent. After a time, sleep may come on, and on waking from this complete consciousness may be regained, or the symptoms may gradually subside. After a very large dose has been taken, severe convulsions may appear in a very short time, and persist, with or without furious maniacal delirium, until near death. Sooner or later, however, the delirium subsides into stupor, and the convulsions into paralysis; and when the dose has been enormous, and especially when the alkaloid itself has been taken, stupor, with great muscular relaxation, may occur very early. Lividity of the face, and evident imperfect aëration of the blood, are not seen in atropine-poisoning, except in the stage of most imminent peril. Death is preceded by marked failure both of the heart's action and of the respiratory forces. In most cases, I think, it is actually brought about by asphyxia.* Post-mortem examinations have shown in fatal cases congestion of the lungs, often with ecchymoses, and a similar state of the membranes and even substance of the brain and cord. According to M. Lemattre,† congestion of the retina is an almost characteristic lesion of atropine-poisoning.

Upon the lower animals belladonna to a great extent acts as upon man, although its influence is much less powerful in them, and very much larger doses are required. Seeming differences of action are in most cases simply apparent, not real. Thus, in the dog, as in man, the pulse-rate is very greatly increased by atropine, while in the rabbit it is not. As will be shown hereafter, the rise of the pulse-rate in the former is largely due to paralysis of the par vagum. Atropine paralyzes the par vagum in the rabbit as much as in the dog, but in the rabbit pneumogastric paralysis, by section or otherwise, is never followed by a rise of the pulse-rate at all comparable to that seen under similar circumstances in the dog. Evidently the action of the drug is identical in the two cases, although the symptoms are different. In their sensitiveness to atropine animals differ very much, and, as a general rule, herbivora are less susceptible than carnivora. Thus, the rabbit may be fed for days entirely upon belladonna-leaves without injury, and many grains of atropine are necessary to kill him. Birds—at least pigeons—I have found will often recover after the hypodermic injection of two grains of atropine, and three grains by the mouth did not prove fatal. A very curious fact, which I have repeatedly verified, is that the pupils in pigeons cannot be dilated by the use of

* See a case reported by S. W. Gross, *Amer. Journ. Med. Sci.*, 1869, p. 401, as a striking instance.

† Quoted by Tardieu, *Sur l'Empoisonnement*, Paris, 1867, p. 752.

belladonna. According to Professor Richet, the monkey offers an extraordinary resistance to the action of atropine.

The close study of the physiological action of atropine can only be made system by system, and I shall now consider the subject under such headings.

*Action on the Circulatory System.**—In the dog and in the rabbit small doses of atropine cause an increased frequency of the pulse, with rise of the arterial pressure. If, however, larger amounts of the alkaloid are used, and especially if the poison is thrown immediately into the venous circulation, there is an immediate fall of the blood-pressure, although the pulse increases as before. Bezold and Bloebaum (*Untersuch. aus d. Physiolog. Laborator. in Würzburg, Heft i.*) state that the dose of atropine can be so graduated as to produce at first a temporary rise of the arterial pressure, followed in a short time by a fall.

In atropinized animals, as is stated both by Bezold and Bloebaum (*loc. cit.*, p. 33) and by Meuriot (*De la Méthode physiol. en Thérap. et de ses Applications à l'Etude de la Belladone*, Paris, 1868, p. 73), and as I have frequently seen, section of the vagi is not followed by any increase of the heart's action, and galvanization of the nerve is incapable of influencing the viscera. It follows that atropine in toxic doses paralyzes either the trunk or the peripheral filaments of the nerve, and, as Bezold and Bloebaum believe, most probably the latter. The observers just named have found that if atropine be injected into the carotid so as to reach the pneumogastric centres before the periphery, there is an instantaneous fall in the rate of the heart's beat,—an indication that upon the cardiac inhibitory centres atropine acts as a direct stimulant, precisely as it does on the spinal cord, the reason that the action is not more manifest under ordinary circumstances being the incapacity of the paralyzed vagus to transmit the central impulse. This asserted stimulation† of the inhibitory centre, if it be correct, accounts very beautifully for the primary brief slowing of the pulse stated to occur in some cases of atropine-poisoning. (See *Stille's Therapeutics*, vol. i. p. 725. Mitchell, Keen, and Morehouse found it in about one-third of the cases after large hypodermic injections; Da Costa in a large pro-

* A long paper upon Calabar bean and atropine has been published by Rossbach and Fröblich (*Verhandl. d. Würzburger Phys.-Med. Gesells.*, 1873), in which results totally at variance with those of all other observers, and many of them at totally at variance with general physiological laws, have been reached. Space cannot be spared for a criticism of this paper, and the reader is referred to the memoir itself abstracted (*London Med. Rec.*, i.) and to the critique of Harnack (*Archiv f. Exper. Pathol. Pharm.*, ii. 307). See also *Pharmacolog. Untersuch.*, Bül. i. Heft 3 and 4.

† The experiments and conclusions of Rossbach and Fröblich confirm the existence of this stimulating action of atropine on the inhibitory centres, but cannot be received as correct, for reasons already given. Harnack (*Archiv f. Exper. Pathol. Pharm.*, ii. 328) finds that the minutest dose of atropine increases the rapidity of the heart after stimulation of its inhibitory centres by muscarine and consequent slowing of its beat. This does not, however, prove that atropine has no action on the inhibitory centres. Further investigation is necessary for a positive conclusion.

portion, *Amer. Journ. Med. Sci.*, July, 1865; and Miss Mary Putnam in some cases, *New York Medical Record*, 1873).

The reports as to the action upon the frog's heart are somewhat at variance, Bowditch and Luciani having noted an increase, Gnauck a lessening, in the cardiac pulsations (*Verhandl. Physiolog. Gesellsch. zu Berlin*, 1881). H. Schapiro states that this variance is accounted for by the fact which he has discovered, that whereas at high temperature (15° C.) the pulsations are diminished, at low temperature (7° C.) they are increased. The explanation of H. Schapiro does not, however, contain the whole truth: it appears to be certain that after large doses of atropine the frog's heart suffers diastolic arrest and cannot be re-excited by galvanic or other stimuli; and Bezold and Bloebaum (*loc. cit.*, p. 48) have found that the same thing occurs when an overwhelming dose of the alkaloid is injected into the jugular vein of a mammal. When, by the division of the spinal cord and vagi, the heart is isolated from the nerve-centres and the vaso-motor nerves are paralyzed, Bezold and Bloebaum have found that atropine lessens at once the arterial pressure. The doses of Bezold and Bloebaum were too large to show the effect of minute quantities upon the heart of the mammal after its isolation from the nervous system. It may be, however, considered settled that *overwhelming doses of atropine act as a direct paralyzant upon the heart-muscle. Minute quantities probably stimulate the muscle*; thus, Ramson discovered that atropine causes in the heart of the octopus pronounced excitation of the muscular fibre; O. Langendorff (*Archiv für Phys.*, 1886) found that when the cut-off apex of the frog's heart was touched with a minute quantity of atropine it immediately commenced to beat; and G. Boyer (*Amer. Journ. Med. Sci.*, July, 1885) noticed that the ventricles of the isolated terrapin's heart are enormously stimulated by minute quantities of the alkaloid, although they are arrested in diastole by larger amounts. This action of the drug upon the heart-muscle is probably the cause of the increased pulse-rate which has been noted as occurring when atropine is given after division of the vagi, and which has been (probably erroneously) attributed to stimulation of the accelerator nerves (see 7th Edition; also articles by Professor E. T. Reichert and myself, *University Med. Mag.*, 1891).

The relation of belladonna to the vaso-motor nervous system is of such practical importance that it deserves the closest study. Brown-Séquard says positively that the drug has the power of exciting the muscular fibres of the arterioles; but, as he nowhere details the reasons for this opinion, I think little weight is to be attached to his statement. In 1857, Wharton Jones, of England (*Med. Times and Gaz.*, p. 28, 1857), announced the fact (confirmed by Lemattre, *loc. cit.*, p. 52) that if atropine be dropped upon the web of a frog's foot, under the microscope the vessels can be seen to contract. Dr. Hayden (*Dublin Quarterly*, Aug. 1863) in repeating these experiments found that if the skin were cut just above the foot, no contraction occurred, and concluded

that the phenomenon was purely reflex. Meuriot (*loc. cit.*, p. 39) has obtained in some cases, but not invariably, the results of the last observer. He has, however, discovered that if the nerves of the leg be divided, no contraction ever takes place. Atropine is an irritant, and it is evident that the contraction caused by its local application is simply, as Hayden believed, a reflex phenomenon, precisely similar to that which occurs on the application of any chemical or mechanical irritant. The experiments of Wharton Jones, upon which so much has been based, must, therefore, be eliminated from the evidence on the question. The problem can be solved only by studying the effects of the remedy administered so as to act on the part solely through the circulation. Meuriot, as the result of such studies on the frog's web, has concluded that there is in the first stages of the poisoning a very slight contraction of the vessels, amounting to nothing more than increase of their tonicity, never to any decided lessening of their lumen. Dr. Harley (*The Old Vegetable Neurotics*, London, 1869, p. 220) has witnessed a more decided contraction of the vessels. I have tried the experiment several times, but obtained no decided results. On the other hand, Bezold and Bloebaum (*loc. cit.*, p. 50) have made similar experiments upon the ear and mesentery of the rabbit, and have never been able to detect any contraction of the vessels, and consequently deny its existence. In these experiments it was not possible to use the microscope,—which detracts greatly from their value.

The evidence derived from direct observation of the capillaries seems to me to be, on the whole, decidedly in favor of their contraction by minute doses of belladonna. I do not think, however, that much weight is to be attached to evidence of this nature. The alterations in the calibre of the vessels are so slight as to leave great play for the imagination of the observer,—a source of fallacy which probably accounts for the different results obtained by different investigators. Much more decisive proof is, however, obtainable from a study of the arterial pressure. I have found that after section of the vagi atropine still has the power of raising very materially the arterial pressure. As atropine does not augment the force of the individual cardiac beat, and as the increase in the number of the cardiac pulsations caused by it after section of the vagi is comparatively slight, it is exceedingly probable that the rise of arterial pressure just spoken of is due to a contraction of the small vessels. This logical conclusion becomes almost a certainty when it is further known that after division of the cord, and consequent separation of the vessels from their vasomotor centres, atropine is powerless to produce rise of arterial pressure, a fact vouched for by Bezold and Bloebaum, and which I can confirm from my own experiments (*Amer. Journ. Med. Sci.*, April, 1873). To this cumulative evidence must be added the experimental fact noted by Bezold and Bloebaum, that when a small dose of atro-

pine is injected into the carotid artery—i.e., into the vaso-motor centres—there is an instantaneous rise of blood-pressure.*

Viewing all these facts together, I am forced to give assent to the proposition that *atropine, in not too large amount, is a stimulant to the vaso-motor centres*; a conclusion in harmony with the action of the drug on all the other motor centres. All observers agree that in the advanced stage of atropine-poisoning, after the blood-pressure has commenced to fall, there is dilatation of the capillaries. It seems most probable that this is due to a direct action of the poison on the muscular fibres in the coats of the vessels; for when directly applied to the web of the frog's foot, atropine, after a time, produces an evidently paralytic dilatation; and Bezold and Bloebaum have found that the arterial muscular coats in atropine-poisoning finally lose their irritability, but that so long as they retain it, galvanic stimulation of a sympathetic nerve does not fail to induce contraction in the tributary vessels.

Action upon the Nervous System.—The delirium which is so characteristic of atropine-poisoning shows that it has especial relations with the cerebral cortex. Professor Albertoni has made a series of experiments to determine whether it inhibits or affects the motor powers of the cortex. He finds that neither the single large dose nor the repeated continuous dose has any power in preventing the epileptic seizure resulting in dogs from the stimulation of the motor zone of the cortex: enormous toxic doses seem only to render the response slower and less vivid (*Arch. f. Exper. Path. Pharm.*, xv. 265).

In 1862, Dr. S. Botkin (*Virchow's Archiv*, xxiv. 85) found that when the vessels of a frog's leg were tied and the animal poisoned with atropine, while paralysis developed itself in the ordinary way in the uninjured leg, the injured leg preserved its motility. He also discovered that the nerve of the leg whose artery had been tied transmitted a forcible impulse to its tributary muscles under the stimulus of a galvanic current much weaker than could elicit the faintest response from the nerve of the opposite side. He concluded, very logically, that atropine acts as a paralyzant to the motor nerve-trunks themselves, and also, since motion persisted in the protected leg after it was completely lost in its fellows, that this influence of the drug was exerted upon the motor trunks before the spinal centres. These experiments have been confirmed by Lemaitre (*loc. cit.*, p. 49), by Bezold and Bloebaum (*loc. cit.*, p. 20), by Meuriot (*loc. cit.*, p. 90), and by Fraser and others, who have proved that atropine, if in sufficient dose, has the power of *destroying the excitability of the efferent or motor-nerve fibres*, but that it must be in very large quantity, so that in mammals death may be caused by the alkaloid and yet a notable amount of functional power be retained by the motor nerves. Bezold and Bloebaum, whose

* It is proper to state that Bezold and Bloebaum attribute this rise to psychical disturbance, without, however, as it seems to me, good reason.

elaborate experiments are especially commendable, affirm that very rarely have they been able totally to destroy by atropine the functional power of the motor nerves, and also have shown that both the nerve-stem and the peripheral intra-muscular nerve-endings are affected. All the experimenters agree that no stage of super-excitability preceding that of depression can be discovered.

Professor Thos. R. Fraser discovered in 1869 (*Trans. Roy. Soc. Edinb.*, xxv. 450) that if a frog receive an injection of about one-thousandth part of its weight of atropine, a condition of perfect paralysis and abolition of reflex action comes on after a time, and lasts from two to four days, to be succeeded by a tetanic stage, with violent convulsions and excessive excitability of the reflex centres. The convulsions of this stage have been shown by Fraser to be spinal, occurring after section of the cord in all parts of the body. Dr. Fraser found (*Exp.* 59, p. 481) that when he protected the hind legs by tying the aorta at its bifurcation, tetanus appeared in them at a time when the anterior legs were completely paralyzed and the brachial nerves were unable to respond to the galvanic stimulation. Again, he was able to produce symptoms closely analogous to those caused by atropine by injecting simultaneously two poisons,—one a stimulant to the cord, the other a paralyzant of the nerve-trunks. These facts would seem to prove that during the paralytic stage of the action of atropine a convulsant condition of the cord is masked by a paralyzed state of the efferent nerves. This conclusion is, however, invalidated by certain facts observed by Fraser, and especially by the recent researches of Ringer and Murrell. Thus, in some of Fraser's experiments the paralysis was at no time sufficient to mask a tetanus; in experiments of all three observers the tetanus did not develop at once in parts in which the nerve-trunks were protected by cutting off their blood-supply; contrary to the observation of Fraser, in a number of experiments performed by Ringer and Murrell, after the aorta had been tied tetanus developed no earlier in the protected than in the unprotected leg. In some of the experiments of Ringer and Murrell the paralyzant effect of the poison passed off—voluntary and reflex action returning—before the supervention of the tetanus. These facts seem to show that the paralysis as well as the tetanus is due to an action upon the centres, the drug so acting upon the spinal cord as first to abolish and then intensify its reflex activity. The explanation of this singular action cannot at present be considered as established. Drs. Ringer and Murrell believe that both the paralysis and the tetanus are due to a depressant action. The theory is that the normal cord has a power of resisting impulses received from the periphery, and especially of preventing their wide propagation among the spinal centres. During the first stage of the atropine-poisoning it is supposed that the motor portions of the cord are so paralyzed as to be unable to form or propagate any motor impulse, and hence the general paralysis. Later on, however, the motor

centrated alkaloidal condition, and consequently has been rapidly absorbed and suddenly precipitated upon the nervous system.

In the experiments of Botkin, made by tying the vessels of the frog's legs, as described on page 208, the investigator found that although for a time irritation of the foot of the perfectly paralyzed leg would cause spasms in the opposite limb whose nerve was protected, yet later in the poisoning, although irritation of the foot of the protected leg caused movements in that leg, no irritation of the opposite poisoned foot was able to induce any response whatever on either side. From this he drew the inevitable conclusion that, while atropine paralyzes first the motor nerves, yet later it acts also on the afferent nerves. The very beautiful experiments of Dr. Fraser, already quoted, certainly show that the afferent nerves enjoy a comparative immunity from the influence of atropine in large doses. For when one leg of a frog was protected by tying the crural artery, during the period of general paralysis any irritation of the poisoned leg would produce immediate reflex convulsions in the unpoisoned extremity,—a demonstration that while the functions of the efferent or motor nerves were suspended wherever the poison reached, the afferent nerves retained more or less of their activity. This of course confirms a portion of the experiments and conclusions of Botkin, and does not disprove that atropine acts to some extent upon the afferent nerves; for a very feeble impulse reaching the cord in its excited condition would cause reflex movements. Bezold and Bloebaum (*loc. cit.*, p. 20) have investigated this subject by exposing the sciatic nerves of a strychnized frog, immersing them for a portion of their course, the one in a solution of atropine, the other in a solution of the phosphate of sodium, and then testing the effect of the application of stimuli in causing reflex movements. The result was not very satisfactory, so many sources of fallacy arising—sources not necessary here to point out—as to vitiate greatly the experiments. They certainly found, however, that the nerve-trunk preserved for some time its power of transmitting impulse even when immersed in a two-and-a-half-per-cent. solution of the alkaloid. Bezold and Bloebaum (p. 25) also repeated the experiments of Botkin, substantially confirming them, but showing that very large doses are necessary to affect seriously the conducting powers of the afferent nerves.

The following experiments of Meuriot (*loc. cit.*, p. 95) prove conclusively that atropine does influence the afferent nerves. He found that if a frog be bound tightly around the body so as to interrupt the circulation, and then be poisoned by atropine in the front part of its body, at first irritations in any part give rise to general spasms, but after a time in order to get any movements of the hind legs it is necessary to apply an irritant to them. Again, the hinder parts of a frog were so bound by ligatures as to cut off on the one side all communication except by the nerves, and on the other to leave free the nerve

and the vessels. A strong injection of atropine was then given, and when the moment came that irritation of the periphery of the leg whose circulation was free would no longer cause reflex spasms, the artery of this leg also was tied, so that both legs, the one atropinized, the other not, were now connected with the body of the frog only by their nerves. Strychnine was given hypodermically, and it was found that, while irritation of the atropinized leg had no effect, stimulation of the non-atropinized leg gave rise to general convulsions. The whole present evidence shows that *atropine depresses the afferent nerves, but much more feebly than it does the efferent nerves*. Miss Mary Putnam (*N. Y. Med. Rec.*, 1873) asserts that if the general tissue of the frog's limb be tied, the vessels and nerves being left intact, so as to prevent diffusion of the poison through the cellular tissue, the sensitive nerves are alone affected by atropine. As no details of experiments are given, the matter rests simply upon the assertion of Miss Putnam. It is very difficult to imagine why a nerve should be affected differently by a poison when reaching it by different routes, and equally difficult to conceive how the poison should reach more effectively the motor than the sensitive nerves by diffusion. Further, it is also almost as unreasonable to believe that any perceptible diffusion through the cellular tissue should occur when the seat of injection is in a distant part of the body. Taking together the facts that Miss Putnam's assertion is unsupported by detailed experiments, is exceedingly improbable, and is seemingly opposed to an enormous mass of experimentation by some of the most experienced and able investigators that have ever lived, it seems to me that it cannot be accepted. It is probable that atropine acts upon the peripheral filaments of the nerves more quickly than upon the main trunks; this is corroborated by Miss Putnam, who states that she has seen galvanization of a sciatic nerve cause indications of pain in an atropinized animal when the peripheral sensation was already lost.

There can be no doubt that in the higher animals atropine acts upon the cerebrum as it does in man, producing the same peculiar delirious intoxication often ending in stupor. It is not necessary to discuss this matter further, except to remark that belladonna is *not* a hypnotic. The fact that the exhibition of a remedy is followed by sleep in disease is no proof that the remedy is in a proper sense a hypnotic. No one would give oyster soup such a cognomen, yet in certain exhausted wakeful states of the system such food may bring back sound sleep. If belladonna ever acts as a hypnotic, it is in this indirect way, by removing some cause of abnormal wakefulness. It can never be relied on, like opium, to induce sleep.

Action on the Voluntary Muscles.—The voluntary muscles escape unscathed in atropine-poisoning. It is true that Lemattre has shown that the contractility of a striated muscle may be destroyed by soaking it in a very concentrated solution of the alkaloid; but long before any

such action can take place in life the animal is killed; consequently after death from belladonna the contractility of the voluntary muscles is found unimpaired.

Action on the Abdominal Canal.—On the non-striated muscles the action of the drug is pronounced, but its exact nature is uncertain. Mouriot states (*loc. cit.*, p. 112) that if the belly of an animal poisoned by atropine be opened, the intestines will be found undergoing violent contractions, and that belladonna is a powerful excitant of the non-striated muscles. On the other hand, Bezold and Bloebaum affirm that they have experimented upon the intestines, bladder, uterus, and ureters, and that in all cases there is a state of marked sedation from atropine, and that, whether a small or a large dose be used (*loc. cit.*, p. 65), there are produced muscular quietness and relaxation in all these organs,—evidences of sedation not preceded by any stage of excitement, and always accompanied by lessening of the electro-muscular sensibility. They state, further, that by the use of sufficient doses absolute muscular paralysis of the organs above named is induced, so that the strongest faradic currents are unable to cause any motion. P. Keuchel (*Das Atropin und der Hemmungsnerven*, Inaug. Diss., Dorpat, 1868) has made a most elaborate series of experiments to determine the effect of atropine upon the inhibitory fibres of the splanchnic nerve.

It has been shown by Pflüger that galvanization of the peripheral ends of the divided splanchnics causes immediate arrest of the peristaltic intestinal movements, and, although the subject has not been absolutely worked out, it is almost certain that some of the splanchnic fibres are the inhibitory nerves of the intestinal coats. Keuchel has found that even when doses of atropine so small as not to affect distinctly the motor nerves are given, galvanization of the splanchnics fails to influence the intestines, whose vermicular movements are still active, and therefore that atropine paralyzes the peripheral inhibitory intestinal apparatus precisely as it does that of the heart. There is, of course, a seeming disagreement between these researches and those of Mouriot and of Bezold and Bloebaum; and the apparent confusion is increased by the assertion of Dr. I. Ott (*N. Y. Med. Journal*, 1883, 170), that minute doses of atropine prevent the production of peristalsis by salt placed upon the intestine, while large doses exaggerate the action of the salt. It would appear from this that atropine first stimulates the intestinal inhibitory nervous system, then paralyzes it. Before the question can be settled, further researches are necessary, but it is possible that all these observers saw and reported correctly, the differences being the result of varying doses. It appears certain that, in full doses, atropine paralyzes the smooth muscular fibres of the intestine, bladder, etc., and it may be that in any dose it depresses their activity directly, but that, by paralyzing more quickly the inhibitory apparatus, it sometimes places the intestinal muscular coat in such a

position that it will respond more vigorously than normal to external stimuli, and also that very minute doses may cause quiet by producing inhibitory stimulation. This view is borne out by the fact that the smallest dose used by Keuchel was 0.075 gr., by Ott 0.015 gr., both observers experimenting on the rabbit. When Ott used 0.45 gr. he got the same result as did Keuchel.

Action on the Respiratory System.—As has been stated, in man small doses of atropine produce no apparent effect upon the respiration, whereas large doses usually accelerate it. In the lower animals acceleration of the respiration under the simple toxic dose of atropine is also, I think, the general rule; but neither in man nor in the lower animals is the increase of the frequency of the respiration an absolutely constant phenomenon. In common with other physiologists, I have heretofore considered the effect upon the respiratory rate the index of the action of the drug upon the respiratory apparatus, the drug being considered a respiratory stimulant if the rate be increased, a respiratory depressant if the rate be lessened. This position is, however, manifestly absurd, since the decrease or increase in the amount of the respiratory movements may more than counterbalance any alteration in the frequency. The only proper test, therefore, of the effect of a drug upon the respiration is the amount of air which is moved under the influence of the drug (see H. C. Wood, *Journal of Physiol.*, 1892). Researches upon the effect of atropine upon the respiratory movement of air have been made by Heubach (*Arch. f. Exper. Path.*, viii.), by E. Orlowski (*Warschau Thesis*, 1891), by E. Vollmer (*Archiv Exper. Path. and Pharm.*, xxx.), and by myself. The experiments of Heubach, Orlowski, and Vollmer were made upon animals under the influence of morphine. My own experiments were made upon both normal, morphinized, and chloralized dogs. The first effect of atropine in the normal animal is to greatly increase the air movement. This primary excitement is usually soon followed by a decrease, which is not, however, sufficient to overcome the first rise; so that the air movement remains for a long time distinctly above the norm. In the chloralized dog the effect of atropine in increasing air movements is constant and pronounced. In my own experiments (two in number), as also in Orlowski's, with a dog under the influence of opium, no increase, but rather a decrease, in the air movement was the result of injections of atropine. In Heubach's and in Vollmer's experiments, which were numerous, atropine distinctly increased the air movement in the morphinized dog.

The action of opium upon the respiration in the dog is at present so little understood that the question of the contra-action of atropine and morphine is entirely apart from that of the action of atropine. The correctness of the older teaching, that atropine stimulates respiration, seems to me established by the newer evidence. As it has been shown by Bezold and Mochaum (*loc. cit.*, p. 59) that atropine affects

the respiration in the dog whose vagi have been previously divided, the drug must be considered to be a *centric respiratory stimulant*.*

After *very large* fatal doses of atropine there is evidently a paralysis of that portion of the peripheral pneumogastric nerve which is connected with the function of respiration; for if in an animal suffering only from a moderate dose the par vagum be cut, respiration is profoundly affected, but when the alkaloid has been more freely given, no marked influence is exerted upon the expiratory rhythm by section of the pneumogastrics. As death approaches in belladonna-poisoning, the blood, which has preserved its normal coloration, may become very dark, and the patient may at last die of asphyxia,—probably not entirely from failure of the centres themselves, but also, in part, from the loss of functional power in the respiratory nerves.

Action on the Glandular System.—One of the earliest and most notable effects of medicinal doses of atropine is dryness of the mouth, due to suppression of the secretions of the mucous and salivary glands. The action of the alkaloid upon the skin is similar. It can scarcely be doubted that this arrest of secretion is nervous; and the experiments of Keuchel indicate that it is due to an action upon the peripheral nerve-filaments. As was first discovered by Schiff, section of the chorda tympani is followed by arrest of secretion of the submaxillary gland, and galvanization of the peripheral end produces a greatly increased flow of saliva. In Keuchel's experiments these phenomena occurred in the unpoisoned animal, but when atropine had been exhibited, galvanization of the peripheral chorda tympani was powerless to excite secretion,—proof that the peripheral end of the nerve was paralyzed.

Elimination.—Atropine escapes from the body chiefly through the kidneys, but that it is also found in other secretions than the urine has been shown by S. Fubini and O. Bonanni, who have detected it in the milk (Moleschott, *Untersuchungen*, xiv., 1892).

Action on the Secretions.—After small doses of atropine the urine is increased,—sometimes, according to Harley, doubled. I am confident, however, that this increase varies greatly, and is not always marked. After very large toxic doses the urine may be at first increased, but is usually lessened very early, and in the latter stages may be entirely suppressed.† Meuriot states that the secretion of urine rises and falls in atropine-poisoning with the arterial pressure. The experiments of Harley upon men (*loc. cit.*, p. 214) would appear to show that medicinal doses of atropine decidedly increase the solida of

* The effect of temperature, psychical disturbance, etc., upon the respiration of the lower animals is so great that only by the greatest care can reliable results be reached. Many of the difficulties are overcome by the previous use of chloral, which puts an end to emotional disturbance, and by maintaining an equable temperature. The reader desiring a fuller discussion of this subject is referred to the paper by the writer mentioned in the text.

† See case of Dr. Gross (*loc. cit.*), also of Dr. Moret (*Ann. Soc. de Méd. de Gand*, 1873).

the urine, slightly the urea and uric acid, very markedly the phosphates and the sulphates.

In regard to the secretions of the alimentary canal, the action of atropine is very uncertain. It has been a matter of traditional and clinical belief that they were increased, and Harley gives some experiments which he claims corroborate this; Meuriot, on the other hand, states that they are lessened. I cannot find, however, any experiments that seem to me decisive; and clinical evidence certainly indicates that the alimentary secretions, if affected at all, are increased.

Action on the Temperature.—In moderate doses atropine causes a pronounced rise in temperature, but in very large decidedly toxic amounts it lessens animal heat. Thus, in the dog, Meuriot has obtained an augmentation of from 1° to 3° C., and Duméril, Demarquay, and Lecomte* of 4° C. In fatal poisoning of the same animal, these observers have noticed a fall respectively of $5\frac{1}{8}^{\circ}$ and 3° .* In man, Meuriot, in the use of medicinal doses, has observed the temperature to rise $\frac{1}{2}^{\circ}$ to $1\frac{1}{8}^{\circ}$, and Eulenburg* $\frac{1}{2}^{\circ}$ to $\frac{3}{8}^{\circ}$.† Harley has seen in man an elevation of 1° F. Drs. I. Ott and C. Collmar (*Therap. Gaz.*, Aug. 1887) have found that the increase of the bodily temperature produced by atropine is independent of the blood-pressure, occurring both when the pressure is elevated and when it is depressed. They also find that there is marked increase both of heat-production and of heat-dissipation, the production being, however, affected more distinctly than the dissipation. It follows from these experiments that the cause of the rise of temperature is increased heat-production, which is the result, in all probability, of an influence upon the nerve-centres. Drs. Ott and Collmar believe that this influence is a stimulation of the thermo-genetic centres in the spinal cord, and that the rise of temperature is paralleled by that which occurs in tetanus. The final fall of temperature in atropine-poisoning is probably caused by the vaso-motor paralysis.

Summary.—From what has been already stated, it is evident that the actions of atropine in therapeutic and in toxic doses are in a sense quite different.

In full medicinal doses it produces a sort of febrile state, with dryness of the mouth, increased rapidity and force of the circulation, quickened respiration, elevation of temperature, and secretion of febrile urine. The rapidity of the heart's action is due to paralysis of the peripheral inhibitory nerve and to stimulation of the heart or its contained ganglia;‡ the increased arterial pressure is caused by increased cardiac action, together with the contraction of the capillaries produced by excitation of the vaso-motor centres. The spinal cord is not sensibly

* Quoted by Meuriot, p. 111.

† These figures are probably all of them Centigrade, though it is not so stated by Meuriot.

‡ Professor Reichert states that in exceptional cases in animals the pulse-rate is decreased by atropine, and believes that this is due to a depression of the motor ganglia of the heart.

affected by these doses; the motor and probably to a much less degree the sensory peripheral nerves suffer lessening of functional activity, although the influence of therapeutic doses of atropine upon them must be very slight. If the dose be sufficiently large, the cerebrum is thrown into a condition of mild delirium, resembling that of fever.

After decidedly toxic doses of atropine, the blood-pressure falls, from dilatation of the capillaries, owing to the paralysis of their muscular coats, and from direct laming of the heart-muscle. The temperature also falls; the muscular system is relaxed, and sensation is impaired, from the paresis of the motor and sensory nerves respectively; yet convulsions may now occur from the over-activity of the reflex centres, the predominance of paralysis or of convulsions varying with the dose, accordingly as the depressing or the stimulating influence is the more powerful. Delirium precedes stupor, which in turn precedes death, from asphyxia, caused by depression of the respiratory centre and of the motor nerve-trunks, or very rarely from syncope, caused by failure of the cardiac muscle.

Local Action.—It is evident that when belladonna is applied to a part it must act locally as a paralyzant, no doubt overpowering the capillary walls, the sensory and motor nerves, and even muscular and glandular cell-action; for, except in the case of the latter, experimental evidence has already been brought forward to prove that, locally and freely applied, belladonna is a sedative poison, and clinical evidence points very strongly to its exerting a similar influence upon gland-cells. A. Zeller (*Virchow's Archiv*, lxvi. 384) has found that a one-per-cent. solution of atropine brought in contact with the blood, outside of the body, has a decided influence in arresting the movements of the corpuscles.

Action on the Eye.—Atropine placed in the eye, or given internally, dilates the pupils of all animals except birds. Accompanying this mydriasis are paralysis of accommodation and an alteration of intra-ocular pressure. In regard to the latter, the subject is so intricate that even the specialists differ in their views concerning it, and I must refer the reader to special treatises upon it. The latest research with which I am acquainted is that of Holtzke (*Archiv für Physiol.*, 1885, 564),* who states that the atropine plainly by its own action lessens the intra-ocular pressure, but that it subsequently increases it by the dilatation of the pupil which it causes.

Before discussing briefly the action of atropine upon the pupil, the fact that a recent American female writer has reasserted the old theory that the movements of the iris are due to erectile tissue, or, in other words, to its blood-vessels, seems to render necessary a few words as to the real motile power of the part. In the first place, it is an indisputa-

* See also *Der intraoculare Druck und die Innervations-Verhältnisse der Iris*. Von Professor Dr. Stellwag von Carion. Wien, 1868.

blo anatomical fact that the iris is largely composed of muscular fibres, and it is a simple common-sense deduction that the muscular fibres are there for the purpose of causing motion, especially since, in many animals, it can be readily demonstrated that while some of these fibres are circular, others are radiating, so that by position they become antagonistic. The paper of Dr. Arlt (*Archiv für Ophthalmologie*, 1869) seems to me decisive. In a very elaborate series of experiments it was found that when the upper cervical ganglion was stimulated the pupil dilated long before any influence upon the vessels was detected, and that on cessation of the stimulation the pupil became natural long before the spasm of the vessels yielded; to my mind a proof that the ganglion has fibres other than vaso-motor,—fibres which control the muscular actions of the iris, and are more sensitive than the vaso-motor filaments; and, secondarily, a proof that the movements of the iris are not due to movements of the blood-vessels. Space cannot be afforded in the present work for a further discussion of this subject. The reader is respectfully referred for further information to books on the physiology of the eye, and especially to Engelhardt's paper, *Beiträge zur Lehre von den Bewegungen der Iris* (*Untersuch. aus dem physiolog. Laboratorium in Würzburg*, Theil ii.).

In considering the action of belladonna upon the eye, it is necessary to view separately its influence when applied locally and when given internally; and I shall consider these influences in the order in which they here stand.

It may be first asserted that the dilatation induced by the local application of belladonna or of its principles is a nervous phenomenon, and not due to a direct action of the drug upon the muscular fibres of the iris; for as all of these, both the radiating and the circular, are of the same nature (*non-striated* in mammals), their antagonism is simply due to position; and it seems inconceivable that mere position should affect the relations between a muscle and a drug. Moreover, decisive proof is afforded by the experiments of Bernstein and Dogiel, who found that while galvanic irritation of the oculo-motor nerve was unable to cause contraction of the pupil in the atropinized eye, yet when the electrodes were applied to the eyes in such a way as to affect directly the iris, contraction occurred,—phenomena explainable only by the theory that the nerve-endings were paralyzed, while the muscle was unaffected. Of the truth of this observation there can be no doubt, as it has been confirmed by Dr. G. Engelhardt (*Untersuch. aus dem physiolog. Laboratorium in Würzburg*, Theil ii. S. 321).

The statement first made by Wharton Jones (*Med Times and Gaz.*, 1857), that the reason atropine does not dilate the pupils of birds is that their irides have no radiating fibres, has been disproved by the beautiful anatomical researches of Alex. Ivanoff and Alex. Rollett (*Archiv für Ophthalm.*, vol. xv. p. 1), confirmed by Johannes Diegel (*Max Schultz's Archiv für Microscop. Anat.*, Bd. vi. Heft i., 1870). Although Professor

Donders (*Accommodation and Refraction*, New Syd. Soc. ed., p. 584) says that the pupillary action of atropine "is slight in birds, in whom it was formerly overlooked," in my own experiments the most thorough application of very strong solutions to the eyes of pigeons has had no distinct effect. In previous editions of this book I ventured the surmise that the lack of action of atropine upon the irides of birds might be due to the muscle being of the striated type. According to the experiments of Szpilman and Luchsinger, this supposition is correct. In the œsophagus of the bird the muscle is non-striated, and atropine paralyzes it; in the œsophagus of the rabbit the muscle is striated, and atropine has no action; in the cat a portion of the œsophagus has smooth muscular fibres, a part striated, and the former is paralyzed, the latter unaffected, by atropine (*Arch. f. d. Ges. Physiol.*, xxvi. 460).

The dilatation of the pupil by the local application of atropine* is certainly independent of any nerve-centres farther back than the ciliary ganglion. This is proved by the following facts. Claude Bernard (*Physiol. et Pathol. du Système nerveux*, Paris, vol. ii. p. 212) and Lemattre (*loc. cit.*) both have found that atropine-mydriasis occurs in animals after section of the oculo-motor, and I have seen it in cases of complete oculo-motor paralysis in man. It also takes place after section of the trigeminus or of the cervical sympathetic, or of both of these nerves, as is shown by the testimony of numerous observers and by my own experiments. In man, I have seen it after paralysis of the sympathetic (*Phil. Med. Times*, vol. i. p. 290). The dilatation of the pupil by the local application of atropine is independent not only of the central nervous system, but also of the ciliary ganglion, and it is therefore due to an action exerted directly upon the *nerve-endings in the iris*. The experiments of Bernstein and Dogiel, confirmed by Engelhardt, already quoted, are in themselves almost enough to establish the truth of this proposition. More direct evidence is not, however, wanting. Thus, Vierordt† has found that atropine locally applied causes mydriasis after the removal of the ciliary ganglion. Professor I. Hoppe (*Die Nervenwirkungen der Heilmittel*, Leipsic, 1856, Heft ii. S. 179) has discovered, and Y. Valentin (*Versuch einer physiolog. Pathologie der Nerven*, Leipsic, 1864, Abtheilung ii. S. 368) has confirmed the discovery, that in the eye of the frog removed from the body atropine will produce dilatation of the pupil. According to Borelli (*Edinb. Med. Journ.*, Nov. 1871), mydriasis is produced by the alkaloid when applied to the eye of a man just dead. Lastly, the presence of the alkaloid in the humors of the atropinized eye has been proved by numerous observers, among whom may be mentioned Lemattre (*loc. cit.*, p. 55) and

* Contraction of the pupil before dilatation noticed in dogs (Reese) and rabbits (Roosbach and Fröhlich) is probably caused reflexly by the irritant action of the atropine.

† Unfortunately, the only notice I have seen of this capital experiment is in Hermann's *Grundriss der Physiologie*. No reference is given, and I have been unable to find the original paper.

Professor Donders (*loc. cit.*, p. 588), who have found that the liquids removed from such an eye are capable of causing dilatation of the pupil of another eye.

It having been demonstrated that the mydriasis of the atropinized eye is the result of an action upon the peripheral nerve-fibres, the question arises, Are the ends of the oculo-motor, the contractor of the pupil, paralyzed, or are the ends of the sympathetic, the dilator, stimulated, or is there a double influence, both of these actions occurring? Both Donders (*loc. cit.*, p. 589)* and Stellwag von Carion (*loc. cit.*, p. 92) insist that the paralysis of accommodation is proof of paralysis of the oculo-motor nerve, and it seems to me they do so with truth. However this may be, there is abundant direct proof that the oculo-motor fibres are paralyzed, since the experiments of Grünhagen, which prove that galvanization of the exposed oculo-motor nerve does not affect the atropinized pupil, have been confirmed by Engelhardt (*loc. cit.*, p. 321) and by Rossbach and Fröblich (*Pharmak. Untersuchungen*, Würzburg, i. 6).

In artificial mydriasis there is, then, undoubtedly peripheral palsy of the oculo-motor. The question arises, Is there also stimulation of the dilating nerve? The evidence as to this is not so positive, but to my mind indicates very strongly that there is such an action. Clinical experience certainly shows that the dilatation produced by a mydriatic is not merely a passive movement of relaxation, but is active, capable of tearing up inflammatory adhesions even when of some firmness. Again, the dilatation that occurs after the paralysis of the oculo-motor nerve in man and after its destruction in animals is not at all equal to that produced by atropine, and, indeed, can be largely increased by the action of the drug; further, in the eye separated entirely from the nerve-centres (see above) atropine still causes a wide dilatation; facts which necessitate the belief either that the alkaloid acts upon the sympathetic fibrillæ, or that the peripheral fibres of a nerve are in themselves nerve-centres, acting upon the muscle of themselves even when separated from their centres.

It has been urged against the view here taken that even the widest artificial mydriasis is increased by galvanization of the sympathetic. De Ruiter states the contrary; but, since Grünhagen, Hirschmann, and Engelhardt separately affirm as the result of personal experiment the correctness of the asserted fact, it must be accepted. Granting its truth, I do not think it warrants the deduction, since it is conceivable that an agent may excite the peripheral filaments of a nerve greatly, and yet not to such a point that they shall be incapable of further excitation.

In conclusion, the action of atropine applied to the eye may be summed up as follows: the mydriasis is the result of a direct influence upon the peripheral nerve-fibres, those of the oculo-motor being cer-

* See also Von Graefe, *Deutsche Klinik*, 1861.

tainly paralyzed, those of the sympathetic and its ally the trigeminal being probably excited.

In regard to the constitutional action of atropine, it is evident that when the alkaloid is administered internally there are only four possible ways in which it can cause mydriasis, and that these are as follows: 1. By acting alone on the sympathetic centres, as a stimulant. 2. By acting alone on the oculo-motor centres, as a paralyzant. 3. By combining these actions. 4. By being carried to the eye, and acting as though locally applied.

Authors are greatly at variance in their conclusions: thus, Harley (*The Old Vegetable Neurotics*) and Haydon (*Dublin Quart. Journ.*, August, 1863) may be cited as in favor of the first view, and Budge (*Ueber die Bewegung der Iris*, 1855), Braun (*Archiv für Ophthalm.*, Bd. v. Abth. ii.), and Hirschmann (*Reichert's Archiv*, 1863) as favoring the second. Neither the first nor the second view is, however, tenable: the first, because of a fact which has been asserted by authorities and which I have experimentally corroborated, namely, that atropine given hypodermically causes dilatation of the pupil after section both of the trigeminal and of the sympathetic in the neck; the second, for the reason that after section of the oculo-motor in animals, or after complete paralysis of the oculo-motor in man, the mydriasis is much less than that of atropine-poisoning.

In regard to the third view, I have noticed that the dilatation of the pupil under the constitutional action of the alkaloid after section of the cervical sympathetic is still greater than that which is normally produced by oculo-motor paralysis. At my solicitation, Dr. T. G. Morton, of this city, cut down to the optic nerve in a rabbit and divided all the structures about it. The pupil contracted very much at the time; the cornea was not sensitive, but recovered its sensitiveness in part after some days. Atropine given hypodermically dilated the eye very markedly, but not nearly to the extent of the other eye. If in this experiment all the ciliary nerves were really cut, the proof is conclusive that the mydriasis is not of centric origin; the reason that the pupil did not dilate so freely as the other being the strong contracting influence it was under, and the great reduction in the amount of blood—i.e., the amount of atropine—entering the eye, owing to the division of the blood-vessels.

An experiment of Lomattre, if it be accurate, is also conclusive in proving that the action of the mydriatics upon the pupil, even when administered internally, is a peripheral one. He succeeded in producing mydriasis in normal eyes by placing in them aqueous humors taken from dogs poisoned with atropine, and even from a fœtus whose dam had been killed by the alkaloid. Dondera, however (*loc. cit.*, p. 589), failed to get the dilatation, and two or three experiments have yielded me the same negative result. It requires no elaborate argument to prove that in this case a negative result does not overpower a previ-

ous positive one: still, the experiments of Lomattre need confirmation. In the Pennsylvania Hospital, under the care of Dr. Morton, not long since, I saw a man who had been wounded by a railroad-accident in such a way that the whole of the temporal bone anterior to the petrous portion was thrust into the side of the head: there was complete paralysis of the facial, of the trigemina, and of the oculo-motor, as could be readily demonstrated upon the man, who lived some months, finally dying suddenly of abscess of the brain. The carotid canal was so pressed upon that the sympathetic, which passed upwards through it to the eye, must have also been paralyzed. The eye was, as proved by the autopsy, separated from all connection with the nerve-centres, and yet when atropine was given hypodermically the pupil dilated. The proof seemed complete that the mydriasis was owing to a peripheral action.

Our knowledge of the action of atropine upon the pupil may be summed up as follows. Atropine applied locally causes mydriasis by paralyzing the peripheral ends of the oculo-motor nerve, and probably by stimulating the peripheral ends of the sympathetic. Atropine given internally causes mydriasis, not by influencing the nerve-centres, but by being carried in the blood to the eye itself and there acting precisely as when applied locally.

THERAPEUTICS.—The results of clinical experience are in strict accord with what is known of the physiological action of belladonna. The chief indication for its use is to *relax spasm*. In the case of voluntary muscles its powers are comparatively feeble, except when it is *thrown directly into the muscle affected*. In this manner Dr. S. Weir Mitchell (*Injuries of Nerves*, Philadelphia, 1872, p. 258) has obtained very marked relief in the fearful spasms following nerve-wounds, and Dr. J. M. Da Costa in rheumatic spasm (*Pennsylvania Hosp. Rep.*, 1868). The benefit derived is evidently due to the depressing effect of the drug upon the terminal nerve-filaments, with which it comes in direct contact, and to a certain extent also upon the muscle itself. When given by the mouth, so small an amount of the remedy reaches the diseased part as scarcely to affect it, and very little or no relief follows. As has been previously shown, the non-striated muscles are more affected by belladonna than are the striated, and clinically the drug is found to be even more efficacious in *spasm of the involuntary* than of the voluntary muscles: in such cases it is often of value used internally. It may be thus administered in *lead colic*,—in *simple spasmodic colic*,—in *spasmodic dysmenorrhœa*,—in *spasmodic constriction of the bowels with obstinate constipation*,—in *laryngismus stridulus*,—in *nervous cough*,—in *asthma*,—in *hiccough*,—in *whooping-cough*,—in which, as originally advised by Bretonneau, it has been largely used and is one of the best-known remedies; also, even in the spasms accompanying the passage of *renal and biliary calculi*, where of course it often fails. Wherever it is possible, however, it should be used locally in spasm of the involuntary as well

as of the voluntary muscles. Thus, in *spasm* of the *urethra*, the ointment should be rubbed in along the canal; in *rigid os uteri*, the extract should be applied directly to the os; in *asthma*, belladonna should be inhaled, by means either of the cigarette or of the atomization of a decoction of the leaves; in *spasm* of the *sphincter ani* from *fissure* or other cause, it should be applied directly to the part by poultice or ointment. Under the present indication may be considered the use of the remedy in *constipation*. In doses of one-quarter to one-half grain of the extract, belladonna is of great service as an addition to laxative pills.

It is, no doubt, by relaxing spasm, or rather by lessening irritability, that belladonna acts in that form of *incontinence of urine* which is seen generally in children. It has been taught that this affection is due to a relaxation of the sphincter, but often the real cause is an irritability of the bladder, so that spasmodic contraction occurs under the stimulus of a small portion of urine. Toxic doses of belladonna cause a paralytic retention of urine by the local action of the atropine in the urine upon the bladder. It is needless to point out more in detail how the indications in incontinence are met. In these cases the drug must be given in as large doses as the system will bear, and the impression should be maintained for weeks. Usually the dose has to be steadily increased.

To relieve Pain.—Physiologically viewed, atropine should be of little value for this purpose; and I think clinical evidence bears this out. Dr. Mitchell has had probably the best opportunities ever afforded for testing this, and he says decidedly that it is of little use in severe suffering. My own experience is to the same effect. There is, however, considerable evidence of its value in *neuralgia*, but it is chiefly as to its efficiency when injected immediately in the neighborhood of a painful nerve, or applied as inunction over its course when superficial. In large quantity, belladonna certainly affects the afferent nerves, and, used as above, may readily relieve pain. It is very probable also that at times it cures neuralgia by modifying the circulation in the affected part. Though these things be so, yet belladonna is almost immeasurably below opium as an analgesic. In some forms of *neuralgia* with *spasm* it is of service by a double action.

To impress the Heart and Blood-Vessels.—Under the idea of its contracting the blood-vessels, belladonna has been highly commended by Dr. Harley (*loc. cit.*) in *pneumonia*, *acute nephritis*, and various other acute diseases. I have had no experience with it in these affections, but the published accounts do not seem to me to indicate that it is of equal value with other remedies or combinations of remedies. In *chronic albuminous nephritis* I have tried it, as recommended by Dr. Harley (*loc. cit.*), but have failed to derive any advantage from it. In *ordinary sore throat* it does good by acting upon the blood-vessels and by relaxing the pharyngeal muscles. It may possibly be of use, given

before the administration of chloroform, to prevent cardiac inhibitory arrest. (See *Brit. Med. Journ.*, 1880, ii. 620.)

As a stimulant to the circulation, belladonna has probably not been employed as much as it ought. Dr. Graves, however, commends it especially when the pupil is contracted in *typhus fever*, and it has been used with asserted advantage in *erysipelas*, *scarlet fever*, etc. In cases of sudden collapse occurring in acute disease and marked by falling of the temperature below normal, with great loss of the arterial tension and free sweating, atropine is of the greatest value. Such collapse is not infrequent in young children in the advanced stages of *pneumonia*, *pleurisy*, or other pulmonic disease, and is also prone to happen in puerperal mania and similar maniacal states occurring in exhausted patients. It is similar in its character to that which is produced by perforations of the stomach or intestine or as the result of surgical or accidental traumatism. It is a condition of *shock* in which the loss of temperature is chiefly the result of vaso-motor paralysis. In surgical cases also it is probable that excessive pneumogastric inhibition is present. Proper treatment of this condition consists chiefly in the free use of external heat, the hypodermic injection of atropine and of the tincture of digitalis, and the internal administration of alcoholic stimulants: of all these drugs atropine is probably the most valuable.

To arrest Secretion.—Arresting secretion of the salivary glands by paralyzing the extreme branches of the chorda tympani has already been shown to be a physiological action of belladonna, and it follows from this that the drug should be useful in *ptyalism*. I have tried it in several cases of *mercurial salivation*, and found that it arrests almost at once the discharge of saliva, and seemingly facilitates greatly the return to health. In *colliquative sweats* it was originally recommended by Professor Da Costa (*Phila. Med. Times*, Feb. 15, 1871), and I have found it of very great service. A full dose of belladonna extract, or one-sixtieth to one-eightieth of a grain of atropine used hypodermically at bedtime, will very frequently prevent the usual *night-sweat*. In *colliquative diarrhæa* it has been recommended by M. Delpage, and very probably will be found of service.

Inunctions of the breast with belladonna ointment are habitually employed for the purpose of arresting the secretion of milk, and in the experiments of Hammerbacher upon a goat atropine given internally lessened the secretion, especially of the watery portions of the milk (*Arch. f. Gesammt. Physiol.*, xxxiii. 228).

Employment in Poisoning.—It is stated that as far back as 1570 it was asserted that opium and belladonna are, in their influence upon the system, antagonistic. In the early part of the present century their employment as counter-poisons was again brought prominently before the profession; but, although a few scattered earlier records of their use as such exist in medical literature, it was not until the paper

of Dr. Wm. F. Norris appeared (*Amer. Journ. Med. Sci.*, Oct. 1862) that general attention was attracted to the subject. Since this publication, very many cases of the use of the one medicine in poisoning by the other have been published. The opposite actions of belladonna and of opium upon the pupils no doubt first suggested the idea of their antagonism; but in the light of recent experiments these apparently opposite effects upon the eye cannot be considered as proving any antagonism between the drugs, since the dilatation is due to a peripheric and the contraction to a centric influence. In an investigation by Dr. J. Hughes Bennett (*Brit. Med. Journ.*, 1874, ii. 547), twenty-one rabbits received what previous experimentation had shown to be a fatal dose of meconate of morphine (10 grains), and afterwards sulphate of atropine; six recovered; and of these six, four some weeks afterwards were killed by a dose of 10 grains of the morphine salt. Eleven rabbits received a dose of sulphate of atropine (1½ to 2 grains), and afterwards 10 grains of the meconate of morphine; seven recovered, and some weeks afterwards the meconate of morphine (10 grains) being given, four of them succumbed to it. Again, two dogs received the fatal dose of meconate of morphine (2½ grains), and afterwards sulphate of atropine, and recovered, only to die some days afterwards from the effects of a second two-and-a-quarter-grain dose of the opium salt. These experiments certainly warrant the conclusion of Dr. Bennett that atropine is physiologically antagonistic to morphine within a limited area, and that it exerts in dogs and rabbits a beneficial influence in opium-poisoning. Dr. Corona (*London Med. Record*, 1877, p. 341) and Professor Bürz (*Deutsch. Med. Wochenschr.*, Jan. 1887) have experimentally reached conclusions very similar to those of Bennett. What I affirmed in the first edition of this work, namely, that our present knowledge of the physiological action of the two drugs renders a complete antagonism very improbable, is still as true as it is obvious.

When the subject in hand is looked at from its clinical aspect, the conclusion of Dr. Bennett is confirmed. To tabulate and discuss the reported cases of opium- or belladonna-poisoning in which the counter-narcotic has been used would require very many pages, and I therefore shall only state my opinion that these records establish the therapeutic value of atropine in opium-poisoning, but this does not indicate, much less prove, complete antagonism between the two drugs. No one would question the value of alcohol in certain stages or conditions of opium-poisoning, and yet no one would assert that opium and alcohol are in any sense antagonistic. In opium-poisoning, death occurs chiefly through failure of the respiration. Atropine is the most powerful and prompt of the respiratory stimulants, and as such is invaluable in the treatment of opium-poisoning. In protracted opium-narcosis the cardiac and vaso-motor actions of atropine are of service; but it should never be forgotten that the main influence for good is upon the respiratory

centres.* The first improvement from atropine in these cases is usually increased frequency of respiration; and as the breathing becomes less embarrassed the other symptoms ameliorate, largely because of the increased aëration of the blood.

The double nature of profound opium-narcosis must not be lost sight of: the blood is saturated with carbonic acid almost to the dead-line, and much of the unconsciousness, much of the failing circulation, much even of the embarrassed respiration, is due to the presence of the gas. As soon as the system is in a measure relieved of this load, it begins to rebound; emetics act, consciousness returns to some extent, the circulation frees itself, and the road leading towards health is entered upon. It is a matter of the gravest practical importance to decide when, how, and in what quantities the mydriatic should be employed. The exhibition of belladonna should, I think, commence as soon as there is decided failure of the respiration. The stomach is so paralyzed in the narcosis from it that it is uncertain how fast absorption will take place from it; and the drug should always be given hypodermically, in the form of the alkaloid if possible. The first injection of atropine should be of such size that it could not possibly do harm; and one-fortieth of a grain is in most instances a fair commencing dose. Very generally several repetitions of this are necessary, and the delicate practical point is to decide how often these repetitions shall be indulged in.

I think that frequently too much atropine is given, and believe that often a great deal of firmness is required in these cases not to use it too freely, especially since reliance is generally placed upon the pupils as a guide. They are in fact a very unsafe guide, as is apparent when it is remembered that while opium contracts them by influencing the nerve-centres, atropine dilates them by acting on the peripheral nerves. It must not be forgotten that in doses of sufficient magnitude atropine paralyzes the nerve-trunks, and may thus increase the danger. A cardinal principle should, therefore, be to give no more of the mydriatic than is absolutely necessary. One-fortieth or one-sixtieth of a grain may be injected every fifteen, twenty, or thirty minutes, as the urgency of the symptoms may demand. The judgment should be formed from a bird's-eye view of the whole case, fresh atropine not being given so long as the respiration and other symptoms are undergoing amelioration, but the dose being renewed so soon as any tendency to a relapse is manifested. Thus, if under the influence of atropine in a case the respirations had risen from four to eight per minute, I would not use the counter-poison again until there was manifested a tendency for the respirations to grow less frequent, or unless for a long period there had been no improvement.

* In the experiments of Heubach and Auerbach it was found that atropine produced very decided effects upon the circulation- and respiration-curves of dogs poisoned with opium. See *Berlin. Klin. Wochenschr.*, 1878, 767.

Whenever there is failure of respiration in other poisonings than that of opium, atropine is useful. It has been especially commended as an antidote to *poisonous fungi*.*

As a Local Sedative.—Locally and freely applied, belladonna is a sedative, and, I believe, to glandular as well as to muscular and nervous tissues. In this way it is often very useful in various local inflammations. In the form of a plaster it frequently appears to do good in *palpitation of the heart*. Its use locally in spasms and in neuralgia has been sufficiently dwelt on. In *mastitis*, or when it is desired to dry up the secretion of milk, its local application to the breast is often very efficacious. Whenever belladonna is used locally, in order to get its good effects it must be employed freely. At the same time, it should be remembered that a number of cases of poisoning by its external application have been reported (*Med. Times and Gazette*, Nov. 1856; also *London Pharm. Journ.*, 1871). In children it must be used with caution; in adults, with a reasonable amount of care, its external use is safe, provided directions be given to have it washed off so soon as any affection of the sight or dryness of the throat is induced.

Having myself no practical knowledge of diseases of the eye, Dr. William F Norris, Professor of Ophthalmology in the University of Pennsylvania, at my request has prepared the following section:

The Use of Atropine in Diseases of the Eye.—Pure atropine, from its slight solubility in water, is only applicable where we desire a moderate effect; the sulphate, however, can be dissolved in water in any desired proportion, and, therefore, is generally employed. When a four-grain solution of this salt is dropped into the conjunctival sac of a healthy and emmetropic eye, we find that in about fifteen minutes the pupil commences to dilate, and that this dilatation rapidly increases, till in from twenty-five to thirty-five minutes it has attained its maximum. The power of accommodation, and consequent ability to read fine print, does not show any marked decrease till twenty-five minutes have elapsed, when the near point commences rapidly to recede from the eye, until in an hour and a half to an hour and forty minutes the power of accommodation is completely annulled, and only objects over twenty feet distant from the eye, or those presenting practically parallel rays, can be distinctly seen. On the second day after the application the power of accommodation begins to return, and increases rapidly up to the sixth day, but is usually not fully regained till from ten to fourteen days; the pupil remains with but little change till the third day, when it rapidly contracts, but has not fully regained its normal state till eleven or twelve days have elapsed.†

* Consult *The Doctor*, 1874; *Brit. Med. Journ.*, ii. 1874; *Arch. Physiol. Normale*, 1877, p. 531.

† For a more detailed discussion of this subject, see *Donders's Anomalies of Refraction and Accommodation*, p. 584, New Sydenham Society, 1864.

The mydriatic action of the drug is far more marked from a moderately strong solution applied to the conjunctiva than from its internal use, even when it has been pushed to the production of symptoms of poisoning. Thus applied, it acts on the intraocular nerves and ganglia; and it has been proved by Graefe and Donders that when the aqueous humor of an animal is drawn off and collected after its application, it contains a sufficient amount of the drug to cause dilatation of the eye of another animal when applied to it. These experiments have been abundantly confirmed by later observers, and the rapidity of its action appears to depend on the thickness of the cornea and the age of the subject selected for the experiment. It will be apparent from the foregoing statements that the use of a strong solution of atropine is not to be undertaken without due consideration, inasmuch as it is likely to debar the patient from any satisfactory use of the eyes for a period of from eight to twelve days. It is, however, invaluable, from its annihilation of the accommodation, where we wish to determine with accuracy the refraction of the eye, and is daily used for this purpose in cases of hypermetropia where the patients find it impossible to relax their accommodation, in astigmatism where it is necessary to determine the exact difference between the two principal meridians of the cornea, and in the rare cases of myopia associated with spasm of the ciliary muscle. To obtain this complete paralysis of the accommodation, a few drops of a four-grain solution should be dropped in the eye, and this repeated after an interval of five minutes. The patient will be ready for examination one and a half hours subsequently. While the foregoing statements as to the action of atropine on the pupil and on the accommodation are absolutely correct as regards young, healthy, and emmetropic eyes, they by no means hold good in irritable, congested, and diseased eyes. Thus, for example, in cases of congestion or of spasm of the ciliary muscle, whether it be due to straining of the accommodation in a hypermetropic eye or to an inflammation of the iris, repeated instillations of atropine on successive days are often required to obtain complete relaxation of the muscle. In the vast majority of cases it is entirely unnecessary to dilate the pupil to obtain a satisfactory view of the fundus with the ophthalmoscope; but where this becomes necessary we can often use with advantage a solution of one-twentieth grain in an ounce of water; a drop or two of this will dilate the pupil, without, however, rendering it absolutely immovable, and with scarcely any interference with the accommodation; on the next day the pupil is much smaller, and on the third day no trace of its action remains. When we use so weak a solution it becomes necessary to wait nearly one hour and a half before complete dilatation of the pupil is obtained, and therefore for practical work a drop or two of a one-grain solution of homatropine is usually preferred, because it produces a transient and much more rapid dilatation of the pupil. In cases of suspected cataract the pupil should always be

dilated; otherwise we may readily fail to discover the lesion, which frequently first manifests itself in a few faint striae shooting out from the periphery of the lens. Moreover, it affords us a valuable prognostic point as to the probable success of any operation where the cataract is ripe; for where the iris fails to dilate *ad maximum*, we may be sure that it is more prone to take on inflammatory action, and more liable to be pressed on by any cortical matter which may remain behind in the eye. Daily experience shows that after the evacuation of the aqueous humor in the operation for cataract, the iris will contract in spite of any previous use of atropine; but as soon as by the closing of the wound the humor reaccumulates and the anterior chamber is re-established, the atropine resumes its sway. It is most useful in all inflammations of the cornea. In *phlyctenular keratitis*, by its local anæsthetic action on the branches of the trigeminus, it diminishes the photophobia and blepharospasm, and seems to mitigate the intensity of the inflammation by its influence in contracting the ciliary vessels, thus diminishing the supply of nutritive material carried to the cornea. Where an ulcer has perforated the central region of the cornea, and a prolapse of the iris has ensued, the energetic use of atropine often enables the radiating fibres of the iris to detach it from the cornea as soon as the opening has been plugged by lymph, and the anterior chamber restored, thus preventing the formation of anterior synechia. Mackenzie long ago called attention to the "healing and anodyne" effect of atropine in ulcers of the cornea occurring in the ophthalmia of new-born children,—a fact since universally recognized, and which holds good equally in the ulcers resulting from other forms of purulent conjunctivitis. It is held by many writers that part at least of this beneficial action is to be ascribed to its diminution of intraocular tension.* In cases of *iritis* a strong solution of atropine should at the outset be applied repeatedly at short intervals until we have obtained a full dilatation of the pupil, and subsequently sufficiently often to maintain the iris in this condition. We thus place the inflamed tissue at rest, diminish its blood-supply, and prevent the formation of posterior synechia, which constitute so frequent a cause of the recurrence of this disease by their mechanically-irritating effect,

* That atropine diminishes intraocular pressure has been asserted by Graefe, Cœcius, and many other good authorities; and a reference to any manual of diseases of the eye will show that it is an accepted doctrine with most clinical observers of the present day. Other weighty authorities, such as Donders and Stellwag, doubt its ability to produce any such effect. Certainly it fails to reduce intraocular pressure in cases of glaucoma. Numerous attempts to decide the question by physiological experiment have been made by Hensen and Volekers, Wegner, Adamuk, Grünhagen, Dor, etc. The results vary, however, considerably among themselves. Those with the manometer are open to the objection that the cutting open of the eyeball for its introduction quite changes the conditions of intraocular pressure and circulation, and that very slight movement of the instrument or eyeball invalidates the results; while those with the tenometer are also unsatisfactory, inasmuch as we have yet failed to obtain any reliable instrument for measuring intraocular tension.

—putting a strain on the iris in its every motion, and hindering that variation in the diameter of the pupil which normally takes place with every change of convergence and with every variation of the intensity of light. Moreover, extensive synechiæ where the iris is plastered down to the anterior capsule by large patches of lymph tend to produce cataract, by interfering with the nutrition of the lens. Where the synechiæ are narrow and tongue-shaped, they may often be torn through by its action, even after the lapse of years. In inflammatory conditions atropine is usually superior to other mydriatics because the effects last longer. In testing for glasses, homatropine, hyoscyamine, or hyoscyne are often advantageous on account of their more transient action, although in irritable and congested eyes atropine is preferable, because it enforces a comparatively prolonged period of accommodative rest, and thus allows the vessels of the ciliary processes and those of the retina to return more nearly to a normal state.

Atropine acts more powerfully in iritis after the abstraction of blood,* and occasionally, where there is much exudation, fails to produce its effect till after the constitutional effect of mercury has been obtained. In some individuals the instillation of a strong solution of atropine, by its rapid passage through the tear-passages into the nose and throat, produces symptoms of slight belladonna-poisoning,—viz., flushed face, rapid pulse, dryness of the throat, slight dysphagia; but this may usually be diminished or prevented by gargling the throat with water, by compressing the canaliculi, or by everting the lower punctum lachrymarum. In some individuals it produces a curiously-irritant action on the conjunctiva, known as atropine conjunctivitis; this is sometimes quite severe, calling forth almost erysipelatous symptoms, at other times bringing out a crop of granulations. This is owing to idiosyncrasy, and will then happen with perfectly neutral solutions. It should in such cases be discontinued, and the conjunctivitis which it has called forth combated by weak solutions of alum and sulphate of zinc or other mild astringent. We find, too, in some cases of iritis, especially those occurring in rheumatic patients with posterior synechia due to repeated previous attacks, that not only do we fail to dilate the pupil, but that atropia acts as an irritant to the eye. We are then obliged to give up its use, and resort to the application of dry warmth and appropriate constitutional remedies. Where there is any tendency to *glaucoma*, atropine should be avoided or used with great care. It will occasionally in chronic glaucoma precipitate an acute attack, while if used in inflammatory glaucoma it causes a marked increase in the already excessive intraocular tension, augmenting the congestion and the pain suffered by the patient and making the attack more severe and more dangerous to eyesight. It is probable that the dilatation of

* Mackenzie, *Diseases of the Eye*, p. 537, London, 1854. Graefe, *Archiv für Ophthalmologie*, vol. ii. part 2, p. 209 (note).

the pupil causes the iris to press against the spaces of Fontana, and that it may thus impede or even stop the lymph circulation in these spaces, which have been already narrowed by disease.

A great deal has been written about the value of belladonna as a prophylactic in *scarlatina*, and authorities differ very much. For a discussion of the subject I must refer the reader to the treatises of Dr. Geo. B. Wood, Dr. Stillé, Dr. Waring, etc. I have never had a decisive opportunity of testing the matter, but have no faith in the efficacy of the remedy. It ought to be tried further, however. The plan practised has been to dissolve two grains of the extract in a fluid-ounce of water, and give two drops daily to a child a year old, adding one drop for every year in older children up to twelve years.

Toxicology.—Sufficient has already been said about the general symptoms of belladonna-poisoning. Those which are characteristic are the dryness of the throat, the increased frequency of breathing, the dilated pupils, the red efflorescence on the skin, the rapid pulse, the active talkative delirium, sometimes convulsions, all ending in abolition of function, as shown by stupor, rapid feeble pulse, cold extremities, and paralysis. If the urine of a patient suffering from belladonna-poisoning be dropped into the eye of the cat or rabbit, it will dilate the pupil; and the diagnostician may avail himself of this test in any doubtful case. Dr. Morel (*Annales de la Soc. de Méd. de Gand*, 1873) calls attention to a sort of laryngitis produced by poisonous doses of belladonna, and characterized by pain in the larynx, roughness of voice, and the expectoration of minute, pearly, tough pellets. It was present in the advanced stages of two cases of poisoning under his care.

The minimum fatal doses of the preparations of belladonna are scarcely known. An enema representing eighty grains of the root has produced death in five hours (*Casper's Wochenschrift*, Feb. 1845); but, on the other hand, recovery has occurred after the ingestion of three drachms of the extract (*Taylor's Medical Jurisprudence*, London, 1873, p. 432). A tenth, or even a twentieth, of a grain of atropine will often produce alarming symptoms; yet Dr. Chambers reports (*Lancet*, 1864) recovery in a child four years old who had taken about two teaspoonfuls of a solution containing a grain of the alkaloid in half an ounce.

After death from belladonna, no characteristic lesions are to be found.

In the treatment of belladonna-poisoning, the first indication is to prevent the absorption of any more of the poison. For this purpose emetics or the stomach-pump should be used. The same difficulties are to be met and the same measures adopted as in opium-narcosis: it is well to exhibit tannic acid freely, because it forms with the alkaloids salts which are soluble with difficulty. After the stomach has been evacuated, the various symptoms must be met as they arise. The exact value of opium in belladonna-poisoning has not, I think, been determined, and its use should only be tentative, although good is to be

expected from its judicious employment. In poisoning by a mydriatic, in order to keep up the respiration and the circulation during the stage of failure of function the same measures should be employed as in opium-poisoning. External stimulation by heat and by mustard, flagellations, etc., artificial respiration, and especially the use of the alternate cold and hot douche, should all be practised as necessary. Physostigma and jaborandi appear to be somewhat antagonistic to atropine within certain limits, and jaborandi has been used in atropine-poisoning (*Lancet*, 1876, i. 346). As this subject can best be elucidated after the discussion of the action of the respective drugs, the reader is referred for further information to the articles upon Calabar bean and jaborandi. After toxic doses of belladonna, there is very generally complete retention of urine; and as this secretion contains the greater part of the ingested poison, and as reabsorption in the bladder is at least conceivable, the catheter should be used early.

ADMINISTRATION.—Belladonna is never used internally in substance. All the preparations of the U. S. Pharmacopœia except two (designated below) are made from the leaves. They are the *tincture* (*Tinctura Belladonnæ Foliorum*—15 per cent., U.S.), dose, ten to thirty drops; the *alcoholic extract* (*Extractum Belladonnæ Foliorum Alcoholicum*, U.S.), dose, one-eighth to one-half a grain; the *fluid extract of the root* (*Extractum Belladonnæ Radicis Fluidum*, U.S.), dose, one to two minims; the *plaster* (*Emplastrum Belladonnæ*, U.S.*) represents its weight of root; the *ointment* (*Unguentum Belladonnæ*, U.S.) contains ten per cent. of extract. The *liniment* (*Linimentum Belladonnæ*, U.S.) is made by adding five per cent. of camphor to the fluid extract. *Atropine sulphate* (*Atropinæ Sulphas*) is most commonly used, on account of its solubility in water. One-sixtieth of a grain of atropine or its salt, given hypodermically, will generally produce slight dryness of the throat or other indications of its constitutional action. Where rapidity of action is required, this is the best method of administering belladonna. In dropping an atropine solution in the eye for local effect the head should be so inclined that the fluid will run out of the outer canthus, whilst pressure may be applied upon the optic end of the lachrymal duct to prevent passage of the solution into the mouth. A number of cases of serious poisoning are on record through the local use of the remedy by ophthalmic surgeons.

HYDROBROMATE OF HOMATROPINE.—Homatropine is an alkaloid artificially produced from atropine, the *hydrobromate* of which is preferred for practical use on account of its being stable and not hygroscopic. It is said to produce, when taken internally, symptoms similar to those

* Constitutional symptoms are readily produced by the free external use of belladonna plaster or ointment; and patients should always be warned to remove the plaster if dryness of throat or disorder of vision come on. For cases of poisoning in this way, see *N. Y. Med. Record*, Jan. 1894, also *Journ. Amer. Med. Assoc.*, ii. 122.

caused by atropine, except that it slows the pulse. This retardation has been proved by Tweedy and Ringer, Beyer, and De Schweinitz and Hare (*Med. News*, 1887, li. 731) to be at least in part the result of a direct action of the drug upon the heart-muscle or its contained ganglia, since in the frog and in the terrapin the application of homatropine hydrobromate to the exposed heart *in situ* reduces very greatly the number of the beats. In the dog injection of the alkaloid into the jugular vein is followed by a fall of as much as thirty or forty beats per minute, which Drs. De Schweinitz and Hare believe to be in part the result of stimulation of the vagi nerves, because section of the vagi causes a marked increase in the pulse-rate, "although not such a rise as would appear if the inhibitory apparatus was intact." This increase of pulse-rate does not, however, to my mind prove that the drug stimulates the vagi, because if the primary slowing of the pulse were the result purely of an action upon the heart-muscle, unless that muscle were completely paralyzed, it would still feel to some extent the removal of the normal inhibition, and respond to section of the vagi by an increase in the rate of its contraction. De Schweinitz and Hare found that the fall of the pulse-rate was accompanied by a marked fall of the arterial pressure: as the production of asphyxia was followed at this time by a pronounced rise in the arterial pressure, it would appear that the fall of pressure is not the result of a vaso-motor paralysis, but of the cardiac influence of the drug.

It has been shown by the experiments of Drs. Tweedy and Ringer, confirmed by Drs. De Schweinitz and Hare, that homatropine produces in the frog a brief period of tetanus, followed by absolute muscular relaxation, with abolition of reflex and voluntary activity, followed in from six to eight hours, if the dose has been properly proportioned, by return of voluntary movements, associated with tetanic spasms of great intensity. The convulsive movements and the paralysis are, according to De Schweinitz and Hare, of spinal origin, as the nervo-trunks and muscles are not affected. The cause of death is centric respiratory paralysis.*

The action of homatropine as a mydriatic has been studied especially by Chas. A. Oliver (*Amer. Journ. Med. Sci.*, July, 1881), Dr. S. T. Risley (*Trans. Amer. Ophthal. Soc.*, 1888), Dr. Jackson (*Med. News*, July 24, 1886), and Drs. De Schweinitz and Hare. The influence of the alkaloid upon the eye is practically identical with that of atropine, except that it is somewhat more feeble and is much more temporary. The pupil begins to dilate in from seven to twenty minutes after the instil-

* Dr. Wm. Mackintosh, in experiments made in the laboratory of the University of Pennsylvania (*unpublished Inaug. Diss.*, 1883), obtained results at variance with those that are cited in the text. He found that the conducting-power of the motor nerves is much depressed by homatropine, and that tying an artery prevents development of palsy in the limb, also that the pneumogastrics are paralyzed. The plausible explanation of these contradictory results is that Dr. Mackintosh used an alkaloid contaminated with atropine.

lation of the drug, and accommodation fails in from forty to ninety minutes: in from one to seventy-two hours the recovery is complete. According to Dr. De Schweinitz, a solution of one in eighty is sufficiently strong to paralyze accommodation completely, provided it be dropped repeatedly into the eye. When it is desired simply to dilate the pupil for ophthalmoscopic examinations, a single application of a solution of four grains to the ounce suffices. Homatropine as a practical mydriatic is greatly superior to atropine, not only because vision becomes normal in a few hours, but also because it is less irritating to the conjunctiva and much less prone to produce serious systemic disturbance. In fact, no further general effect than a little slowing of the pulse has as yet been noted after its most repeated use.

STRAMONII FOLIA—STRAMONIUM LEAVES. U.S.
STRAMONII SEMEN—STRAMONIUM SEED. U.S.

The leaves and seeds respectively of the *Datura Stramonium*, or *Jamestown Weed*, a coarse, bushy, annual herb, three or four feet high, growing in waste places both in this country and in Great Britain, and readily distinguished by its large, funnel-shaped, whitish, fetid flowers, and its quadrivalve spinescent capsules. The leaves are large, smooth, ovate, irregularly sinuate, with large acute teeth. The seeds are small, brownish black, reniform, with a feebly-bitterish narcotic taste. The active principle is an alkaloid which was discovered by Geiger and Hesse, and named *Daturine*, but which, according to Ladonburg, is a mixture of atropine and hyoscyamine.

PHYSIOLOGICAL ACTION.—The physiological evidence as to the identity of *daturine* and *atropine* is in strict accord with the chemical proof. The symptoms of poisoning by stramonium differ in no respect from those of belladonna-poisoning, although Laurent (*De l'Hyoscyamine et de la Daturine*, Thèse, Paris, p. 22, 1870) asserts that irregularity of the heart's action is more marked under the influence of stramonium. The same accelerated pulse, the same elevation of temperature, the same wild delirium, the same increased frequency of respiration, the same widely-dilated pupils, the same red efflorescence on the skin, the same restlessness or convulsions, occur in both cases, and, when the dose has been sufficiently large, end alike in abolition of the functions of circulation, respiration, and innervation,—stupor, general paralysis, weak, rapid, thready pulse, threatened asphyxia, constituting the phenomena of the closing scene in poisoning from either narcotic.

The most careful, minute investigation of the physiological action of daturine which I have met with is that of Charles Laurent, already quoted. In his experiments that observer found that under the microscope the capillaries of the frog's web could be seen to contract upon the application of daturine, even after division of the nerves of the limb; that the pulse-rate and arterial tension are both augmented by small doses of the poison, but that by large doses the arterial tension is

diminished, although the pulse is still increased in frequency; that when the heart is completely separated from all connection with the central nervous system, daturine reduces the number of its beats; that respiration is accelerated by the alkaloid, even after section of the pneumogastrics; that by moderate doses of the alkaloid the conducting power of the sensory or of the motor nerves is not destroyed; that the muscular contractility is not affected; that small doses increase, large ones diminish, intestinal peristalsis. Elaborate discussion of these facts seems unnecessary. It is seemingly demonstrated, both from a chemical and from a physiological point of view, that *daturine* and *atropine* are identical.

THERAPEUTICS.—Stramonium may be used to meet precisely the same indications as belladonna. It has been especially employed in spasmodic *asthma*, chiefly in the form of cigarettes made by rolling up the dried leaves. These are often very efficient when there is no organic disease; but their use requires some caution, as very alarming symptoms, if not fatal results, have been produced by them. In the form of cataplasms, stramonium leaves are often applied with advantage to painful *local inflammations*, *inflamed hemorrhoids*, etc.

ADMINISTRATION.—The official preparations of stramonium are all made from the seeds. They are the *extract* (*Extractum Stramonii Seminis*, U.S.), dose, one-fourth to one-half grain; the *tincture* (*Tinctura Stramonii Seminis*—15 per cent., U.S.), dose, ten to twenty minims; the *fluid extract* (*Extractum Stramonii Seminis Fluidum*, U.S.), dose, one to two minims; and the *ointment* (*Unguentum Stramonii*, U.S.), containing ten per cent. of the extract.

TOXICOLOGY.—Accidental poisoning, especially of children, by stramonium, is very common. In all points, as regards both symptoms and treatment, stramonium-poisoning and belladonna-poisoning are alike.

HYOSCYAMUS. U.S.

Hyoscyamus niger is a coarse herbaceous biennial, indigenous in England, and naturalized in the Northern United States, whose leaves and flowering tops of the second year's growth are official. The leaves are large, oblong-ovate, deeply sinuated, and very hairy. In 1821, Peschier announced the existence of an alkaloid in *hyoscyamus*, but it was not until 1833 that Geiger and Hesse succeeded in obtaining it pure. According to Geiger, when slowly crystallized, *hyoscyamine* occurs in transparent needles, and in star-shaped or bushy clusters of crystals. According to the recent researches of Ladenburg, *hyoscyamus* contains two alkaloids: one is crystallizable, has the same chemical formula as atropine, and constitutes the *crystalline hyoscyamine* of commerce, and its sulphate is the *Hyoscyaminæ Sulphas* of the U.S. Pharmacopœia; the other is amorphous, constitutes the *amorphous hyoscyamine* of commerce, and, although it has the same chemical formula

as hyoscyamine, is diverse from it; to it Ladenburg gives the name of *hyoscine*. Its salts are crystallizable.

PHYSIOLOGICAL ACTION.—Both Schroff and Düllenberg have noticed in man, as the result of the ingestion of hyoscyamus, dryness of the throat and mouth, brief sinking of the pulse-rate, followed by increased frequency, mydriasis, giddiness, muscular weakness, and insecurity of gait. The experiments of Schroff, of Laurent, and especially of Harley (*The Old Vegetable Neurotics*), indicate that hyoscyamus is much more of a hypnotic than is belladonna. Yet Harley's recorded observations would seem to show that in some individuals hyoscyamus induces insomnia. According to Harley, the primary sinking of the pulse is much more marked after hyoscyamus than after its sister-narcotic. Laurent (*De l'Hyoscyamine et de la Daturine*, p. 15) affirms that the delirium caused by hyoscyamus is calm, while that produced by belladonna is furious; but on page 19 of his book is recorded a case of henbane-poisoning in which the delirium was "furious." Schroff (*Wochenbl. der Zeitschr. der Gesellsch. der Aerzte zu Wien*, 1865) asserted that pneumonia is a constant and even characteristic lesion of hyoscyamus-poisoning in the rabbit; but Lemaitre (*loc. cit.*) has never seen more than little scattered points of hyperæmia; and in Laurent's experience even these have always been absent.

In the elaborate research of Laurent it was found that the capillaries of the frog's web contracted after the local application of hyoscyamine, even when the nerves had been previously severed, and also after the hypodermic use of the poison; that small doses augmented both the pulse-rate and the arterial tension, while large doses increased the former and diminished the latter; that the direct application of the alkaloid to the heart produced a rapid diminution of the number of its beats; that moderate doses increased the rapidity of respiration even after section of the pneumogastrics; that upon the nervous system, the muscles, and the intestines, the action of hyoscyamine was the same as that of daturine. The more important of these conclusions were also experimentally arrived at by Heilmann (*Beiträge zur Kenntniss der physiol. Wirkungen des Hyoscyamins*, etc., Jena, 1873). Dr. R. Gnauck found (*Verhandlung. d. Physiolog. Gesellsch. zu Berlin*, Aug. 1881) that hyoscyamine agrees with atropine in its action upon the vagus and heart-muscle, but is less powerful and persistent in its influence, and also acts as a powerful soporific: it further appeared especially to dilate the internal abdominal vessels.

THERAPEUTICS.—Hyoscyamus may be used to fulfil any of the indications for which belladonna is employed. Clinical experience appears in a measure to bear out the assertions of various authorities as to the superiority of hyoscyamus as a hypnotic. It has been much employed by alienists in various forms of delirious insanity (*West Riding Lun. Asyl. Med. Reports*, v.; *London Pract.*, xvii. 17, xx. 85; *Lancet*, 1879, ii.; *Archives of Med.*, 1880). Many of them claim that hyoscyamine

has a very special calmative effect. The diagnosis and treatment of hyoscyamus-poisoning are identical with those of belladonna-poisoning.

The preparations are the *extract* (*Extractum Hyoscyami*, U.S.), dose, one to three grains; the *tincture* (*Tinctura Hyoscyami*—15 per cent., U.S.), dose, half a fluidrachm to two fluidrachms; and the *fluid extract* (*Extractum Hyoscyami, Fluidum*, U.S.), dose, five minims.

Before we can reach positive results with hyoscyamus it is necessary that the *isolated* crystallized *alkaloids* be separately studied. Dr. J. C. Shaw (*Journ. Nerv. and Ment. Dis.*, vii. 27) has recently partially studied crystallized and presumably pure *hyoscyamine*, and found that it affects the system of voluntary movement and the circulation, including the heart and the vaso-motor system, exactly as atropine does. In a single experiment the respiration did not seem to be affected as by atropine; but this is contradicted by results arrived at by previous experimenters, and needs confirmation. Upon man Dr. Shaw believes, as do many other alienists, that hyoscyamine acts as a soporific. He states that it is less powerful as a mydriatic than is atropine, and that it diminishes the respiratory rate. It must be remembered that these studies have been made upon lunatics; before the conclusions can be accepted as established, much more elaborate experimental researches are necessary, also studies upon normal individuals, and especially contrasting studies made with atropine and hyoscyamine upon maniacs; by the use of alternate doses upon the same individual any difference of action of the two drugs could readily be detected. It should also be remembered that in his studies upon normal men Dr. Richter noted no tendency to sleep (*Neurolog. Centralbl.*, i. 294).

In a careful comparative study of hyoscyamine and atropine upon a case of acute mania by Professor Sydney Ringer, the two alkaloids were found to act practically alike (*Practitioner*, March, 1877). Commercial *hyoscyamine* was formerly very impure, and a grain has been given with impunity; but one-fortieth of a grain of the pure alkaloid has produced violent poisoning (*Lancet*, 1879, i. 474).

COCA. U.S.

The leaves of the *Erythroxylon Coca*, a South American shrub, which is very largely cultivated in Peru and neighboring countries, resemble in size and shape those of the tea, but are not dentate, and are distinguished from most medicinal leaves by a slightly-curved line, running from the base to the apex, on each side of the midrib, and produced by the peculiar folding of the leaf in the bud. In 1855, Gardeke discovered in coca an alkaloid to which he gave the name *Erythroxylene*; but this principle was first thoroughly studied by Dr. Albert Niemann, from whom it received the name *Cocaine*, by which it is now usually known. It occurs in colorless, transparent prisms, soluble in seven hundred and four parts of cold water, and forms with the acids very bitter, soluble,

crystallizable salts; besides cocaine, the leaves contain a peculiar tannin, known as *coca-tannic acid*.

PHYSIOLOGICAL ACTION.—From the days of the Incas the leaves of the coca plant have been enormously used by the natives of Western South America as a stimulant, and it is stated that about forty million pounds of them are annually harvested. Mixed with ashes or a little lime, they are chewed, and are said to increase greatly for the time being the muscular strength and endurance. Although coca is thus employed habitually, no scientific observers have given detailed reports of the symptoms which it causes in the South American natives, observers contenting themselves with the mere statement that the physical and mental powers of the natives are greatly stimulated by the drug. Moderate doses appear to increase temporarily, to a very extraordinary degree, both physical and mental power. Various travellers concur in praising the peculiar sense of calm and happiness, the insensibility to fatigue, and the increase of bodily and mental activity which the drug produces.

Montegazza states that when he took two hundred grains of the leaves he was in a short time plunged into a condition of peculiar physical beatitude, in which he seemed to be isolated from the rest of the world and to live in a peculiar atmosphere of active calm. In a little while there came also a sense of plenitude of power, which was accompanied by a real increase of physical ability, so that gymnastics which in his ordinary condition were impossible to him became easy. This state was succeeded by a natural profound sleep, lasting sometimes the whole of twenty-four hours. After very large doses of coca, in Dr. Montegazza's case, a peculiar series of symptoms occurred to which the name of "cocaine intoxication" was given. Thus, on one occasion he took thirty-five grammes, and an hour later nine grammes, etc., until he had taken in the course of two hours sixty grammes in all. The heart, which after the earliest dose had been slow in its action, directly after the second dose suddenly became rapid and very violent in its beats; but at the end of the two hours the palpitations had ceased, although the pulse was still one hundred and twenty-eight per minute. There was now a condition of intoxication similar to that which is produced by hashish. M. Montegazza was possessed by a feeling of intense beatitude and inner joyousness, while a succession of visions and phantasmagoria, most brilliant in color and form, trooped rapidly before his eyes. He seemed to himself to look upon a world of shifting and incessant activity, as into a kaleidoscope. He rapidly passed into a delirious condition, in which he appeared to himself to be unconscious, although when addressed he would answer rationally. To his own consciousness he was, as it were, buried in a rovery, or perhaps a more accurate description would be to say that he felt as though, by a sudden rush of intellectual and emotional life, he was carried out of himself, and knew not whether he was in or out of the body. An hour or two

later he was sufficiently calm to say to his friends "that God was unjust, in that he had made man to live without eating coca. I prefer a life of ten years of coca to one of a thousand years without it." As this state was passing off, he was seized with an irresistible desire to reproduce its delirium by taking more coca. Finally, however, he fell into a condition of sleep, which lasted only three hours. After this he was able to resume at once his ordinary occupations, and offered no physical evidence of his coca debauch.

The moderate daily use of coca, according to our best information, is not injurious, and increases the working powers; but, according to Professor Poeppig, the habit of the excessive use is readily formed, and produces very serious results. The first symptoms are usually those of disorder of the digestive organs. Little by little the power of digestion is lost; an incurable insomnia is developed, emaciation becomes extreme, ascites appears, and the patient finally dies in a condition of general marasmus. Other authors especially dwell upon the enfeeblement of the intellectual faculties as very marked in those who use the stimulant to excess. Dr. Tschudy states that the inveterate coca-chewer can be recognized by his uncertain step, his general apathy, his sunken eyes surrounded by a deep purple aureole, his trembling lips, his green encrusted teeth, and his excessively fetid breath, with the peculiar blackness about the corners of the mouth.

Already in this country victims of the cocaine habit have in a number of cases presented themselves for treatment. Usually the cocaine has been taken as a substitute for or an aid to morphine. It is, I think, perfectly safe to withdraw the cocaine at once. In a case under my own care, in which fifteen grains had been taken hypodermically daily, the abrupt withdrawal was followed simply by diarrhoea, dyspepsia, and nervous depression, which subsided in the course of two or three days. (For cases, see Dr. Grundlach, *Schmidt's Jahrb.*, Bd. cxxii., 1886; also Mattison, *Med. Register*, 1887.)

Pronounced aphrodisiac properties have been attributed to coca, but they seem to rest rather upon tradition than upon demonstrated experience. According to M. Unanne, the ancient inhabitants of Peru represented Venus by a female figure with a coca-leaf in her hand, and the coca still plays an important part in the nuptials of the Indians.

It has been affirmed by Tschudy and Unanne that coca is able to take the place of food; but this is clearly not the case. Dr. Weddell himself states that although an Indian chewing the coca could go or foot many hours without fatigue and without food, yet at the end he would eat more at one repast than he himself would take in two days. He accords with Bibra (*Die Narkot. Genussmittel*, 1855) in stating that the coca has the power of putting aside for some time the sense of hunger. While, however, it may mask the appetite, it certainly does not nourish the body, and it is, indeed, most probable that the absence of hunger is the outcome of a local benumbing of the gastric nerves.

Thomas Moreno y Maiz (*Thèse*, Paris, 1868) made several crucial experiments by keeping animals in pairs without food, and giving to one coca freely. These experiments have been repeated by B. von Anrep (*Pflüger's Archiv*, xxi., 1880), and in every case the animal which received the coca died at least as early as its mate.

The symptoms which have been present in cocaine-poisoning, or have been produced by the coca-leaf or its preparations, in the United States or in Europe, differ essentially from the descriptions of those said to be caused by the plant in the South American natives.* I believe that in no recorded cases has there been anything at all resembling the beatific visions and exhilarations described by Mantegazza. Ordinarily, in the mildest cases of poisoning with us, there is a great restlessness and nervous excitement, but no sense of beatitude; rather a condition of fear and terror. With this state comes usually distinctly accelerated pulse, increased frequency of respiration, and, perchance, muscular twitchings or even mild convulsions. In the more severe cases of poisoning the symptoms vary; sometimes there has been nausea, vomiting, rapid, almost imperceptible pulse, great perspiration, collapse with or without loss of consciousness; in other cases the pulse has been slow and feeble, and sometimes pronounced cyanosis, with slow or almost arrested respiration, has been the most alarming manifestation. The pupils are usually dilated, but are reported in some cases as "contracted." After very large doses convulsions usually occur; they are often violent and epileptiform; not rarely, at times, at least, they are partial, and in many cases opisthotonos has been pronounced. Consciousness rarely escapes; usually it is simply lost, but sometimes it is merged into a mania with hallucinations and delusions, which mania may become violent and even homicidal, as in a case reported by Mattison.

PHYSIOLOGICAL ACTION.†—Very small doses (one- to three-one-hundredths of a grain of cocaine) produce in the frog no other symptoms than some evidences of excitement. After doses of from one-tenth to one-fiftieth of a grain the frog becomes quiet, with an apparent increase, however, in the reflex activity, sometimes amounting to tetanus, followed by increasing palsy and failure of the respiration; very large doses produce symptoms of paralysis.

* Professor H. H. Rusby, who has studied the coca question carefully in South America, affirms that the difference between the action of coca when fresh and the coca of commerce, or its alkaloid, cocaine, is very distinct. He believes that the difference is due to the presence in the fresh coca of a peculiar volatile aromatic substance which is destroyed during the process of drying and exportation (*Therap. Gaz.*, 1883).

† The chief physiological papers upon cocaine, which I have studied in the original, are those of B. von Anrep (*Arch. f. Gesammt. Physiol.*, Bd. xxi., 1880), U. Mosso (*Arch. Exp. Path. Pharm.*, Bd. xviii.; also *Pflüger's Archiv*, 1890), H. Alms (*Arch. Physiol.*, 1886, Suppl. Bd.), Dr. I. Ott (*Toxicological Studies*, Phila., 1874), Dr. Laffont (*Compt.-Rend. Soc. Biolog.*, 1847, also *Compt. Rend. Acad. Sci.*, or.), Arboing (*Compt.-Rend. Soc. Biolog.*, 1888), R. Fleischer (*Deutsch. Archiv Klin. Med.*, 1888, xii.), Langlois and Richet (*Compt.-Rend. Acad. Sci.*, cxi.), Hubert A. Haro (*University Med. Mag.*, vol. i.), and E. T. Reichert (*Ibid.*). I have also seen the abstracts of the paper by Nikolshy and Danini, contained in the memoir of Von Anrep.

In the domestic animals the symptoms vary. In the rabbit there is first a peculiar state of quiet, followed in a few moments by a condition of great excitement, in which the animal springs and jumps about. A few minutes later the rabbit again becomes quiet, and now, although trembling much, is so weak that he moves with difficulty. The tremblings increase until they merge in convulsive movements of the legs, while at the same time there is partial paraplegia; pendulum movements of the head are very marked, and finally epileptiform convulsions appear, while simultaneously a peculiar tetanic rigidity seems to indicate spinal excitement. The lethal dose for a rabbit is put at a grain and a half per kilo. Dogs and cats are said to be more susceptible to the action of cocaine than is the rabbit, and to suffer similar symptoms, but especially with the dog the evidences of mental excitement are more pronounced.

Nervous System.—The most susceptible portion of the body to the action of cocaine is the cerebrum. The peculiar sense of calm which follows moderate doses of the drug is evidently the result of the action on the brain, which eventuates, after a sufficient dose, in the peculiar ecstasy so graphically described by Montegazza. According to the description of Von Anrep, this delirium is almost equally pronounced in the dog: thus, an habitually very quiet animal, directly after the injection of the cocaine, will begin to dance and leap, never standing still for a moment, and continually circling around the experimenter. The movements are not at all those of convulsions, but voluntary, and accompanied by every expression of joy and exhilaration. This may continue for hours, the animal then becoming gradually quiet, and passing finally into his normal condition. If instead of a moderate dose a toxic one has been given, there is first a period in which the animal is very restless, but seems full of terror and anxiety; the least sound frightens him, causing him to tremble and to drop his tail between his legs. He does not appear at this time to know his master. Rhythmical movements of almost all portions of the body accompany this state. Fifteen or twenty minutes later the mental condition alters, and the dog becomes apparently full of joyous excitement. He barks loudly, runs from one person to another, licking them, and giving all the characteristic signs of joy and pleasure. After a few moments this condition gives way to one of increasing feebleness: the dog gradually becomes unable to move, rhythmical movements, cramps, and convulsive symptoms appear; the pendulum-like swinging of the head becomes very violent, and at last narcosis, with epileptiform convulsions, develops. It is evident that many of these symptoms are psychical.

The stimulating influence of cocaine upon the cerebrum is further shown in the results reached by Mosso, namely, that the reaction time of elementary perceptions is lessened, although the drug produces no noteworthy difference in the capabilities of nerves of conducting impulses.

B. von Anrep believes that the drug has a very distinct and peculiar

influence upon the *semicircular canals*, thereby causing the peculiar pendulum-like motions of the head, the lack of co ordination, and the rolling convulsions especially seen in doves.

Spinal Cord.—According to the researches of Von Anrep, the convulsive movements are of cerebral origin, and are arrested by section of the spinal cord; but the experiments of L. I. Tumas (Arch. f. Exper. Path. Pharm., xxii.) indicate that they do not arise in the psycho-motor centres of the brain-cortex, since he found not only that the local application of cocaine lessens the irritability of these centres, but also that during the convulsive stage of cocaine-poisoning the centres are less sensitive than normal. Danini appears, however, to have found that the section of the cord does not prevent convulsions in the hind feet, and the experiments of Mosso show that when the cord is cut in the dog and the animal cocainized, the irritation of the nerve-trunk or of the surface will produce in a little while general muscular rigidity. Both Mosso and Von Anrep are in accord with other observers in stating that reflex activity is at first increased by cocaine, and the evidence seems to show that while the convulsive movements of the poisoned animal originate chiefly in the brain, yet there is a primary stage of excited reflex activity, the result of a direct action upon the spinal cord. The motor paralysis and the loss of reflex activity which finally occur in cocaine-poisoning are probably in part the result of an influence upon the nerves; but that they are chiefly due to a direct sedative action upon the spinal cord seems to follow from the experiments of Mosso, who found that when he so bound the hind legs of the frog as to prevent the access of cocaine there was a rapid loss of reflex activity, and indeed a complete paralysis, at a time when both the motor and the sensory nerves were still intact.

An observation made at a certain stage of the poisoning by Dr. Ott, viz., that irritation of the posterior columns of the spinal cord produces no effect, while a prick of the anterior column is followed by the usual result, shows that there is the same difference in action upon the sensory and motor tracts as upon the corresponding nerve-trunks.

Nerves.—Although cocaine appears in general poisoning to have a very distinct spinal action, almost all observers agree that the sensory nerves after sufficient doses are finally paralyzed; but Professor Mosso (see *Pflüger's Archiv*, 1890, p. 557) believes that the respiratory centre is more susceptible to the action of cocaine than are the sensory nerves, and certainly doses of the alkaloid not dangerous to life have no perceptible general effect upon the sensory nerves. The experiments of Nikolsky, of B. von Anrep, of Ott, and of Laffont, seem to prove that the sensory paralysis is preceded by increased functional activity, which is in accord with the observation of Mosso, that in doses of 0.05 to 0.1 gramme cocaine increases in man the sensibility of the skin.

Dr. Ott found that in a certain stage of the poisoning, irritation of the posterior column of the spinal cord produced no effect, whilst a

prick of the anterior column was followed by the usual result, which would indicate that the centrifugal or efferent conducting fibres are the last to be affected by the alkaloid; but Mosso's experiments upon Tritons led him to conclude that the power of conducting impulses efferently, or from the centre, is first lost in the spinal cord poisoned with cocaine.

The *motor nerves*, according to Danini, in the frog remain irritable until after death; but, according to Nikolsky, their functional activity is first increased and afterwards destroyed. Ott also asserts that cocaine depresses the motor nerves, and Moreno y Maiz found that when he tied the iliac artery of a frog on one side and administered cocaine anteriorly, there came a time when irritation of the poisoned limb caused no movement, while irritation of the protected extremity provoked very distinct general reflexes. At the same time there was diminished motility in the non-protected limb as compared with the protected one. These facts, of course, indicate that the drug finally depresses both motor and sensory fibres, but that its action upon the motor is subordinate to that upon the sensory nerves. Ott also noticed that there is a time in the poisoning when irritation of the central end of a cut sciatic nerve produces no response, while irritation of its peripheral end causes muscular action, and thereby confirms the view that the drug affects the sensory earlier and more powerfully than the motor nerves. H. Alms found (*Archiv für Phys.*, 1886, Suppl. Bd.) that a five-per-cent. solution of cocaine in contact with the isolated ischiatic plexus of the frog caused absolute anæsthesia of the leg and apparent loss of motor power, the leg lying motionless and trailing behind. Nevertheless, strong irritation upon the front leg of the frog caused immediate movements which were shared by the cocainized hind leg, showing that the motor filaments were not paralyzed. The experiments of Alms indicate that the extreme peripheral filaments of the nerve are first affected, since at a certain period most severe irritation of the skin produced no pain in the poisoned rabbit, although the injection of irritating materials evidently caused violent pain.

Mosso found that when locally applied cocaine is capable of suspending functional activity in motor nerves, and I think it must be considered as demonstrated that cocaine is a paralyzant to both motor and sensory nerves, although it acts much more powerfully upon the sensory nerves.

Circulation—Before the research of Professor Edward T. Reichert (*American Lancet*, May, 1891) much work had been done to determine the action of cocaine upon the circulation, but the results obtained had been so discordant and the work itself so fragmentary that the only positive conclusion that could be drawn was that the influence of the poison upon the circulation is subordinate to its action on the respiration, the heart in fatal poisoning always continuing to beat after the arrest of respiration.

The discussion of the early evidence, which was contained in the text of the eighth edition of this book, will be found given below in a

foot-note.* The conclusion which Professor Reichert reached, that the discrepancies in the statements of the early investigators have been due chiefly to the doses employed and to the varying susceptibilities of the various animals studied, seems to be correct. Professor Reichert's research was made with a full knowledge of what had been done before him and the difficulties of the matter: his experiments were upon dogs, and the conclusions which he arrived at are as follows:

"When the full train of effects is slowly developed by the repeated

* According to Von Anrep, as well as to the earlier observations of Nikol'sky, the heart of the cocaralized frog is gradually weakened and arrested in diastole; but Mosso found that minute doses of cocaine increased the rapidity and power of the systolic contractions in the cut-out frog's heart, while larger doses caused systolic arrest. The suggestion offers itself that the diastolic arrest of the heart asserted to take place in general poisoning is the result of the long-drawn-out asphyxia; but Dr. H. G. Beyer (*Amer. Journ. Med. Sci.*, July, 1885) affirms that while small doses of cocaine increase the action of the isolated heart of the terrapin, large doses arrest it in diastole.

In the earlier investigations of Ott, of Von Anrep, and of Laborde, a rise in the arterial pressure followed the injection of cocaine into the circulation of the mammal. Although it is not positively stated in the text of the memoirs that the animals were not curarized, there seems to be little doubt that the experiments were made upon non-curarized animals. As cocaine disturbs the respiration, and also produces wide-spread muscular contractions, it is necessary to experiment upon animals whose respiratory and muscular systems are paralyzed in order to obtain accurate knowledge of the direct immediate action of the alkaloid upon blood-pressure, since asphyxia and muscular contractions notably increase blood-pressure.

The experiments of Vulpian (*Compt. Rend.*, 1884, vol. ii, p. 385) and of Berthold (*Centralbl. Med. Wissenschaft.*, 1885, p. 435) do not satisfactorily determine the effect of cocaine in curarized animals. Vulpian obtained in a single experiment a very marked rise of the arterial pressure which was maintained for three minutes, when upon the injection of a second dose the pressure fell; while, according to Berthold, distinct permanent elevation of the blood-pressure is never produced by cocaine in curarized animals, although in some cases he had noticed a slight rise lasting for one or two minutes. Large doses of cocaine cause a pronounced sinking of the blood-pressure. Mosso considers the failure of the alkaloid to cause rise of the arterial pressure in the curarized animal to be owing to the curare "paralyzing the influence" of the cocaine; but curare, unless given in overwhelming doses, does not profoundly affect either heart or vaso-motor system, and it is not probable that Berthold and Vulpian used the curare so unskillfully as sensibly to affect the circulation. After section of the spinal cord no rise of the arterial pressure is produced by cocaine (Danini and Berthold). The theory of Vulpian, that cocaine depresses the heart by causing anaesthesia of the pericardium, does not seem to me to be sustained. There is also great variance of testimony in regard to the effect of the alkaloid upon the pulse-rate and upon the vagi. Von Anrep states that the pulse-rate is usually increased, but that this increase is not marked in rabbits, while in Ott's experiments upon dogs the pulse usually becomes slower. Von Anrep also states that the vagi are paralyzed by large doses of cocaine, while Ott, Nikol'sky, Laffont, and Dardus (*Deutsch. Med. Wochens.*, 1887, 122) declare that it does not affect the vagi, and Berthold states that previous section of the vagi has no effect upon the course of the symptoms caused by cocaine. Further, Mosso states as the result of experiments made with artificial circulation in extirpated kidneys that small doses of cocaine have no sensible effect upon the blood-vessels, while large doses paralyze them; but Dr. H. G. Beyer (*Amer. Journ. Med. Sci.*, July, 1885) found in his studies upon the terrapin that both large and small doses of cocaine produce contraction of the blood-vessels by a direct action, whilst the plethysmographic studies of Mosso have led him to the conclusion that in man therapeutic doses of cocaine cause contraction of the vessels, and Laffont asserts that one of the chief actions of cocaine is to contract the vessels by affecting the nerve-endings. Dardus affirms that marked narrowing of the vessels of the ear can be seen in the rabbit when cocaine is injected, but that if the sympathetic be previously divided no distinct contraction will occur in the dilated vessels.

injection of very small doses (0.001 gramme to the kilo of body-weight), the pulse-rate is at first decreased, then increased, and finally decreased. Very small doses decrease the rate by stimulating the cardio-inhibitory centres; small to moderate doses increase the rate by depressing these centres, and in some cases by depressing also the cardio-inhibitory ganglion; large doses cause a transient decrease, followed by a rise or a permanent decrease, the decrease being due to a depression of the accelerator or motor ganglion in the heart, and the increase to the factors before mentioned. The cardio-inhibitory centres are invariably affected, being primarily stimulated and secondarily depressed; but the action on the peripheries is inconstant; a primary stimulation I have not been able to detect, and the depressant action is sometimes manifest to a profound degree very early in the poisoning, and at others is absolutely absent up to the appearance of death. The height of the pulse-curves is in inverse relation to the frequency of the beat.

"The arterial pressure is always increased, unless it be after large doses, when it may temporarily be diminished and then increased, or permanently be lowered. The increase is due to a stimulation of the vaso-motor centres in the medulla oblongata, to a slight extent to a direct stimulation of the vessel walls, and to the depression of the cardio-inhibitory apparatus. The fall of pressure is due chiefly to a depression of the heart, and at times to a similar action on the vaso-motor centres and peripheries. The effects on normal and curarized animals are identical, unless in the latter curare has been used to excess."

At present writing it does not seem probable that the narrowing of the blood-paths is the sole cause of the rise of arterial pressure under cocaine, since Mosso found that minute doses of cocaine increased the rapidity and power of the systolic contractions in the cut-out frog's heart, a finding which is in accord with the statements of Dr. H. G. Beyer (*Amer. Journ. Med. Sci.*, July, 1885), based upon experimental research, that small doses of cocaine increase the action of the isolated heart of the terrapin. The final action of the large doses of cocaine upon the heart is still somewhat in doubt, since Mosso affirms that the heart may be arrested in systole. On the other hand, Von Anrep, Nikolsky, and Beyer have noticed that the heart of the frog or of the terrapin is suspended in diastole. The bulk of the evidence is certainly in favor of final depression and diastolic arrest.

Muscles.—There is a distinct contradiction as to the effect of cocaine upon the striated muscles. Alma, Nikolsky, and B. von Anrep state that the latter are not affected by the alkaloid, while Ott affirms that it acts upon them like veratrine, and is confirmed in this by Buchheim and Eisenmenger (*Pflanzenstoffe*, 2d ed., 885). The tracings given by Ott would appear to prove that the muscular contraction is prolonged by cocaine, and can hardly be accounted for by a condition which M. J. Rossbach and B. von Anrep (*Pflüger's Archiv*, xxi. 243) allege to be produced, viz., a peculiar sensibility of the muscle similar to that pro-

duced by curare, and, like it, caused by a lessening of muscle-tonus by paralysis of the peripheral nerve-endings. The results obtained by Ott find confirmation in the experiments of Professor Berthold upon the effects of the local application of cocaine upon the frog's muscle (*Centralb. Med. Wissensch.*, 1885), and also in those of Professor Mosso, who found that both in the frog, the dog, and the man the excitability of the muscles is increased by small doses, and paralyzed by large doses of cocaine. Cocaine is, therefore, a *muscle poison, stimulating and afterwards depressing the functional activity*. This influence of the alkaloid is, however, probably too slight, as compared with its effects upon other portions of the organism, to be very apparent in general poisoning. Nevertheless, the experiments of Mosso suggest that the influence is greater than it seems, for he found that in man, when the muscles were exhausted by work and fasting, the exhibition of cocaine in the dose of a grain and a half more than doubled the response to stimuli. These extraordinary experiments of Mosso have all appearance of correctness, and throw a peculiar light upon the assertions of travellers, that cocaine in the South American Indians enormously increases the power of withstanding fatigue. The present difficulty in the way of the full acceptance of the natural deductions from them is the fact that, in America and in Europe, cocaine has *appeared* to fail as a stimulant during fatiguing labors.

Temperature.—The rise of rectal temperature in cocaine-poisoning sometimes amounts to as much as 8° F. It is certainly not due to the convulsions, as it usually occurs before the motor disturbance.* In fatal cases it is followed by a fall, so that before death the temperature may become subnormal. In the calorimetrical experiments of Reichert, the rise of temperature was found to be due to a great increase in the heat production, but at present it is impossible to say why or how this rise of heat production is produced. The assertion of Mosso, that the rise of temperature occurs after section of the spinal cord, does not seem to be proven (see Reichert, p. 443).

Elimination.—According to Moreno y Maiz, cocaine is eliminated by the kidneys.

Urinary Secretion.—Dr. J. M. Da Costa states that the hypodermic injection of cocaine, in doses of one-half to one grain three times a day, markedly increases the flow of urine without altering its specific gravity (*Med. News*, xlviii. 679). According to Dr. Bignon, however, the single large dose of cocaine causes an anuria which may be followed by excessive secretion, or may be so prolonged as to cause uramic symptoms (*Journ. Amer. Med. Assoc.*, July, 1887). Further, both Drs. Ott and Atherton P. Mason (*Bost. Med. and Surg. Journ.*, Sept. 1882)

* P. Langlois and Charles Richet have found that the temperature of the cocaineized animal has a great effect in determining the amount of cocaine necessary to produce convulsions. The higher the temperature, the smaller the dose necessary, and when the animal was kept at a temperature of 39° C., only tonic convulsions were produced.

found that when cocaine is taken habitually it not only lessens the secretion of urine but also markedly decreases the elimination of urea. Dr. Mason employed very large doses of cocaine during prolonged exercise. It is, therefore, very probable that this drug diminishes tissue-waste, although Dr. Mason himself states that Gazeau has obtained contrary results. In Dr. Ott's experiments the urine became filled with crystals of oxalate of calcium. Tarehanoff has noticed sugar in the urine of poisoned animals, but Von Anrep affirms that the sugar and the albumen, which is also frequently present, are caused by the asphyxia induced by the drug.

Dr. Richard Fleischer, in three experiments, found that cocaine reduced the elimination of nitrogen, and in a single experiment that it lessened the urinary sugar produced by the administration of phloridzin. Although these experiments seem to have been carefully performed, they are hardly a sufficient basis for the positive conclusion that cocaine checks protoplasmic waste.

*Eye.*²—When a watery solution of cocaine is dropped into the eye there occurs a slight contraction of the pupil, followed within a few minutes by dilatation. The first contraction is probably reflex and due to the irritation of the conjunctiva. The maximum dilatation for a four-per-cent. solution is usually reached about the end of the first hour; an hour later it has sensibly begun to decline, and in from twelve to twenty-four hours the pupil returns to normal. The dilated pupil is to some extent responsive to light and to accommodation, and the mydriasis is rapidly overcome by eserine. V. Linbourn states (*Arch. Exper. Pharm. u. Path.*, xxx.) that the dilatation is not so great as that caused

² The following comparison of the action of mydriatics was prepared at my request by Dr. Geo. De Schweinitz, of the eye clinic of the University Hospital:

Atropine, daturine, hyoscyamine, hyoscyne, and duboisine have each the power to dilate the pupil *ad maximum*. Because cocaine leaves the pupil responsive to light, and because its mydriasis is readily overcome by a myotic, like eserine, it has been classed as a feeble mydriatic. Nevertheless, with it as wide a dilatation of the pupil may be obtained as with any of the five other drugs, provided the observation is made by a weak light and when convergence and accommodation are relaxed. Such precaution is unnecessary with the others.

After mydriasis and ciliary paralysis are produced with atropine full accommodation is restored in from ten to fourteen days; with daturine in about ten days; with hyoscyamine in from six to eight days; and with duboisine in about four to five days. The duration of the mydriatic action of hyoscyne resembles that of hyoscyamine. It is, however, a more powerful mydriatic. Dilatation of the pupil under the influence of cocaine declines markedly within an hour, but the return to normal is usually not complete until the end of twelve hours.

Atropine, daturine, hyoscyamine, hyoscyne, and duboisine all produce ciliary paralysis, and may hence be employed to correct anomalies of refraction; atropine and hyoscyamine should be preferred,—the former if the condition of the eye-ground calls for prolonged rest. When dilatation of the pupil is necessary in the treatment of inflammatory diseases of the cornea and iris, atropine should be chosen. The great objection to the use of duboisine is the pronounced systemic disturbance which it occasionally produces. Cocaine is useless in the determination of errors of refraction, but is very useful as a dilator of the pupil for diagnostic purposes.

Atropine certainly increases intraocular tension, so also probably do hyoscyne, daturine, and hyoscyamine. Cocaine has the power to lower the tension of the normal eye.

by atropine and can be increased by atropinizing; that the cocainized pupil still reacts with light and accommodation; that the dilatation may be overcome by the local action of pilocarpin, and that the vessels within the eye are notably contracted. The ocular tension is lowered rather than increased. The power of accommodation, while distinctly lessened in its range, is never entirely abolished (Knapp, *Cocaine*, 1885). Dr. Jackson affirms that cocaine causes a peculiar irregularity of the corneal surface which is not due to any loss of epithelium, although it may proceed so far as to cause a notable haziness. Würdinger produced distinct corneal opacity in the rabbit by repeated instillations of a five-per-cent. solution. It seems, however, probable that this opacity was the result of corneal inflammation due to the inability of the anesthetized eye thoroughly to protect itself: nevertheless, some oculists affirm that cocaine distinctly predisposes the eye to excessive inflammation upon irritation or operative procedures.

G. N. Durdau (Deutsch. Med. Wochenschr., March, 1887) states that in dogs poisoned with cocaine not only is there dilatation of the pupil but also a manifest protrusion of the eyeball, with excessive opening of the lids; phenomena which are similar to those that follow irritation of the cerebral end of the divided sympathetic nerve in the neck, and which Durdau concludes to be due to stimulation by cocaine of the sympathetic nerve-centres, because he has found that they are prevented by section of the sympathetic nerve in the neck either with or without accompanying section of the oculo-motor nerve. He has further experimentally determined that section of one-half of the spinal cord one and one-half centimetres from the point of the calamus does not interfere with the production of the cocaine phenomena in either eye, and therefore locates the ocular centre which is affected by cocaine in the medulla spinalis below the medulla oblongata. The conclusions of Durdau are, however, rendered extremely improbable by the primary fact that the cocaine dilates one pupil when applied locally without affecting the other pupil. The dilatation must be due to a local action. Moreover, the experiments of Nikolsky, Holtzke, Limbourg, as well as of Scholer and Pflüger (quoted by Limbourg), show that cocaine applied to the eye immediately after section of the sympathetic does dilate the pupil, although later, when sufficient time has elapsed for degeneration of the sympathetic fibres to occur, the alkaloid is powerless. Limbourg has made the curious observation that electrical irritation of the cornea may restore to such an eye the power of responding to cocaine. This change of sensibility may, perchance, be due to a stimulation of the nerve-filaments in the eye by the electricity. However this may be, certainly the drift of the present evidence is to show that cocaine dilates the pupil by stimulating the peripheral sympathetic fibres.

Respiration.—Small doses of cocaine increase distinctly the rapidity of the respiration, and in some cases also the depth (Von Anrep, Mosso, Danini, Ott, and Nikolsky). After toxic doses the respirations become

at first rapid and more shallow, then irregular with interruptions, after each of which the respiratory movements begin deep and slow, but become more rapid and shallow until the next stand-still. As Mosso found that after section of the vagi cocaine causes an enormous increase of the rapidity of the breathing and at the same time so modifies the rhythm that the expiration is no longer more quick than inspiration, it must be considered that the drug acts directly upon the respiratory nerve-centres as a respiratory stimulant. The first stimulant effect of cocaine upon the respiratory centres appears to be followed after fatal doses by a paralyzing influence which leads to death from asphyxia.

Intestines.—According to Von Anrep, the intestinal peristalsis is markedly increased by moderate doses. After large doses this increase is followed by great sluggishness deepening into paralysis. Tarchanoff states that coca increases the mucous secretions, but Von Anrep affirms that it decreases them.*

According to the experiments of Peter Albertoni (*Archiv f. Gesammt. Physiol.*, 1890-91, xlviii.) and of B. Danilewsky (*Ibid.*, 1892, li.), cocaine in sufficient concentration acts upon all forms of protoplasm, first exciting and then paralyzing its functional activity.

Summary.—Cocaine is a cerebral stimulant, producing peculiar mental excitement, ending after large toxic doses in narcosis, with epileptiform convulsions, which are probably of cerebral origin. In the poisoning there is at first increased reflex activity, followed by paralysis of voluntary motion and of reflex activity, which are chiefly due to a direct action upon the spinal cord, the sensory side of the cord being probably more sensitive to the drug than the motor side. Toxic doses depress and finally paralyze the sensory nerves, and in a much less degree the motor nerves. The conclusion as to the action of cocaine upon the circulation, which seems justifiable by the present physiological knowledge, is that cocaine in moderate dose is a mild stimulant, directly increasing the action of the heart and also narrowing the blood-paths by a centric and probably also by a peripheral influence, and that in overdose it acts as a depressant to the circulation, lessening the force of the heart and widening out the blood-paths. Upon striated muscles cocaine appears to have a peculiar though very feeble action, which is not manifested during poisoning by it. It has been asserted that cocaine acts as a powerful diuretic, but the drift of present evidence is to show that it has no definite influence upon the amount of urine secreted: what evidence is available indicates that it decreases elimination of urea. Upon the eye cocaine acts as an energetic mydriatic. It is a powerful stimulant to the respiratory centres, increasing the rapidity and fulness of the respirations, but if the dose be sufficiently

* M. H. Gley states (*Compt. Rend. Soc. Biol.*, lii. p. 540) that when cocaine is injected into the portal vein it produces comparatively little effect, and he believes that it is destroyed in the liver. This is criticized by Chouppe (*Ibid.*).

large it after a time causes the respirations to become very shallow, and finally paralyzes the respiratory centres. Moderate doses are said to increase, large doses to paralyze, peristalsis.

Local Action.—Locally applied,* cocaine acts as a very distinct and certain anæsthetic, as was noted by Moreno y Maiz in 1862, and by Von Anrep in 1880, although it was not until September, 1884 (*Wien. Med. Wochenschr.*, Nov. 1884), that Dr. Karl Koller demonstrated the practical value of the drug. According to the observations of Von Anrep, the nerves of special sense are as readily affected as those of common sensibility: thus, cocaine placed upon the tongue abolishes at the place of contact, for the time being, the sense of taste. At the point of contact there is at first marked pallor, but after a short time very pronounced redness. In sensitive membranes like the conjunctiva, cocaine also causes at first much pain. The primary pallor is alleged to be due to a very powerful constriction of the small blood-vessels, and has led Dr. F. H. Bosworth to the conclusion that cocaine produces *rigid contraction in unstriated muscular fibres* whenever it comes in contact with them (*New York Med. Record*, Nov. 15, 1884). The anæsthesia is not, however, due to any spasm of the vessels, but to a direct action upon the nerve-trunk. Applied to the bared nerve, cocaine paralyzes first the sensitive and afterwards the motor fibres (Feinberg, *Berlin. Klin. Woch.*, March, 1887). It has been found by Arloing (*Lyon Medical*, May, 1883) that the concentrated solution of cocaine placed on the bared nerve produces a distinct organic change in the nerve.

THERAPEUTICS.—Cocaine appears to act with certainty as a local anæsthetic whenever it can reach the nerve-filaments in sufficient concentration. The skin will not allow it to pass, while the conjunctival and nasal mucous membranes are very permeable, and those of the larynx, throat, and vagina are penetrated with more and more difficulty, in the order of their naming. Even in disease of the eye, when a deep operation is to be performed, the solution of the anæsthetic must be reapplied at various stages of the operation. To the nasal surgeon the alkaloid appears to be invaluable, while the gynecologist finds it less serviceable, but even he is, by its careful use, able to perform many operations without pain. In painful ulcers, fissures of the anus, etc., its application will afford temporary relief. It is affirmed by various observers that excessive pain is apt to be felt when the anæsthetic effect is going off, and that this, in many cases, overbalances the first relief. It is probable that this pain is the result of the congestion, as Dr. Carl Seiler tells me that after nasal cauterizations this after-pain can be at once arrested by incising the part slightly so as to cause a local bleeding.

* Francois-Frank (*Archiv d. Physiol. Norm.*, 1892, vol. iv.) shows that cocaine locally acts as a paralyzant both upon nerve-centres and all forms of nerve-fibres, and proposes its use for the purpose of the physiologist.

Dr. P. H. Bosworth claims that cocaine is not only extraordinarily efficacious as a *hemostatic* in various surgical cases, but that topically applied it will so constrict the blood-vessels of an acutely inflamed mucous membrane as to arrest the disease. In *bronchitis* he applies it by means of atomization, using a two-per-cent. solution, and also putting the solution freely on the nose and throat. Dr. Bosworth affirms that the effects of cocaine upon mucous membranes last for many hours,—a statement hard to reconcile with the general testimony as to the brevity of the primary bleaching. My own experience is that whenever a local inflammation is so situated that cocaine can be properly applied to it, immediate relief from pain will be afforded, and that in some acute mucous inflammations the effect is permanent. Thus, it is often possible to arrest an acute *coryza* at once by an application of a ten-per-cent. cocaine solution to the nostrils. In *hay fever*, in the peculiar irritated sore throat of *advanced phthisis*, in chronic *laryngitis*, in *inflamed hemorrhoids*, even in open ulcerated *cancers* and other painful affections, cocaine as a palliative is invaluable. In *boils* and *carbuncles* it must be injected directly into the part in order to afford relief.

The tendency to congestion which follows cocaine-anæsthesia cannot at present be explained, unless it be due to a relaxation of exhaustion following over-stimulation. It is a matter of great practical importance in surgery. In 1885 (*Therap. Gaz.*, Jan. 1885) Dr. P. D. Keyser reported a number of cases of severe inflammation in the eyeballs after operations in which cocaine had been used, and I believe oculists have now reached the conclusion that cocaine distinctly lessens the resistive power of the conjunctiva and cornea, and that after its employment active and irritating antiseptic fluids, like solutions of the bichloride of mercury, are not always well borne. (For an elaborate discussion of the subject, see paper by Adam Frost, *Amer. Journ. Med. Sci.*, April, 1887.)

Drs. R. J. Hall and Halsted (*N. Y. Med. Journ.*, Dec. 6, 1884) have made the very important observation that injecting a solution into a nerve-trunk paralyzes sensation over the whole distribution of the nerve for about twenty-five minutes. In some cases advantage may be taken of this. They used as much as thirty-two minims of a four-per-cent. solution; but this produced severe constitutional disturbance, such as great giddiness, severe nausea, staggering, cold perspiration, etc.

For local use a four- to ten-per-cent. solution may be employed, and when the part is not readily permeable, as in the vagina, it should be thoroughly reapplied once or twice at intervals of five minutes. Many minor surgical operations can be performed without pain by injecting cocaine hypodermically and restraining the circulation by pressure. Thus, if a tight band be placed around the proximal end of the finger, and cocaine injected, a *felon* may be opened freely without suffering. In a similar way a tumor may be incised from a lip, or a hare-lip operation performed, if pressure be made around the part by a wire clip.

Even in the trunk a superficial tumor may often be removed without suffering after a concentric series of minute injections of a solution of cocaine around its base.

The stimulant effect of coca upon the cerebrum naturally led to the hope that it would be found advantageous in neurasthenia, melancholia, and hysteria, and as a general tonic and stimulant in acute and chronic diseases with exhaustion. Clinical experience has not, however, entirely confirmed this expectation. I have tried it thoroughly in a number of cases of *melancholia* without any benefit whatever, and this experience is, I believe, in accord with that of most if not all alienists. (See *Journ. Mental Science*, July, 1887.) Sometimes it produces in the beginning of its use a temporary relief, but this effect is not pronounced, and almost invariably after a few doses anorexia or other disagreeable symptoms demand the withdrawal of the remedy. In *neurasthenia* and *hysteria* it usually does more harm than good: sometimes, however, the fluid extract added to wine or other alcoholic drink seems to exert some stimulant and stomachic influence. In the form of large doses of the fluid extract, coca has appeared to me to be of service during the breaking off of the *opium habit*, exerting some stimulant influence upon the nervous system, and restraining the tendency to *diarrhoea* and loss of appetite. Some European clinicians have found cocaine of service in the treatment of *serous diarrhoeas*. It is undoubtedly of value for the relief of *excessive vomiting*, especially when due to gastric irritation. Dr. Thomas D. Dunn (*Therap. Gaz.*, 1888) states that hypodermic injections of one grain control the pain of *migraine*. Dr. Aschenbraidt (*Deutsch. Med. Wochens.*, ix. 50, 1883) asserted that, in doses of 0.15 grain, cocaine was a valuable stimulant during forced marches; but in a series of careful trials with it by the medical rowing crew of the University, it appeared to have no value, and the general experience seems to conform with this result.

The best preparation of coca for internal use is the *fluid extract* (*Extractum Coca Fluidum*, U.S.), the dose of which is one-half to two fluidrachms. The dose of cocaine (*Cocainæ Hydrochloras*, U.S.) is one-sixth to one-half grain.

TOXICOLOGY.—The number of cases of poisoning by cocaine is very great, and although large doses have been recovered from, excessively violent symptoms have followed the use of smaller amounts. It is remarkable, also, that in many of these cases the drug has been employed for a local effect. The fatal cases, to the details of which I have had access, are those reported by Professor Kolomnin, twenty-four grains into the rectum for local anæsthesia; Dr. F. M. Thomas, four per-cent. solution used locally for toothache, in unknown quantity; Dr. Knabe, four-per-cent. solution, twelve drops given hypodermically to a girl of eleven years, death in forty seconds (for details, see Cocaine, Dr. J. B. Mattison, *Med. Reg.*, vol. i., 1887); Dr. J. H. C. Simes, one drachm of twenty-per-cent. solution injected into the urethra, followed imme-

diately by violent convulsions, ending in death in twenty minutes, autopsy proved that urethra was not ruptured (*Med. News*, 1888). A fatal case is said to have been reported in *Odontologie*, 1890, vol. x. Half an ounce of a two-per-cent. solution of cocaine injected into hydrocele and allowed to stay about a minute is said to have caused death (Paul Berger, *Bull. Mem. Soc. Clin. de Paris*, xvii., 1891).

On the other hand, large amounts of the drug have been recovered from. Von Ploss (Husemann, *Die Pflanzenstoffe*, 2d ed.) reports twenty-two grains taken by an apothecary, by the stomach, with spontaneous recovery, although the urine was suppressed for twenty-four hours. In another case ten grains taken hypodermically in the course of five hours produced complete unconsciousness, excessive failure of circulation, slow respiration, recovery under treatment (J. S. Spear, *Med. Rec.*, 1885); Dr. E. Caudwell (*Brit. Med. Journ.*, vol. i., 1885) reports recovery after the hypodermic injection of five grains, which produced convulsions with asphyxia. A case reported by Dr. W. Finlay (*Australasian Med. Gaz.*, vol. vii., 1887) is interesting, because six grains given hypodermically to a pregnant woman lowered the pulse to 38, and the breathing to 5, but did not cause a miscarriage.

Some of the most remarkable cases of poisoning by small quantities are those reported by Dr. T. H. Burchard, ten drops of a four-per-cent. solution injected hypodermically, unconsciousness and apparent death in four minutes; Myerhausen, eight drops of a two-per-cent. solution upon the conjunctiva produced in a girl of twelve years violent symptoms; Dr. Kennicott, a case of violent symptoms produced by cocaine in hay-fever; Dr. George T. Stevens, one in which four minims of a three-and-a-half-per-cent. solution, given to a strong man, produced violent convulsions, followed by mania; Dr. Grosholz, three drops of a four-per-cent. solution in the eye; Dr. A. Frost, one drop of a one per-cent. solution in the eye produced in a child of fourteen marked poisoning (see *Med. Register*, 1887; *Therap. Gaz.*, 188); Ramaden Wood (*Australasian Med. Gaz.*, Aug. 1886) reports violent poisoning with four minims of a twenty-per-cent. solution. A number of cases are on record in which very severe symptoms have been produced by one grain given hypodermically (see Mattison, *loc. cit.*; also Addinsell, *London Lancet*, vol. i., 1888; also Pitts, *London Lancet*, vol. ii., 1887); and it is plain that although this dose has been used to a considerable extent, its employment is unjustifiable. The occasional effects of the local application of cocaine are very remarkable. In addition to cases mentioned may be cited—marked syncope produced by application to the nasal mucous membrane of a four-per-cent. solution by Dr. Ziem (*Brit. Med. Journ.*, Nov. 21, 1885); ten hours' poisoning produced by application to the larynx (Heymann, *Deutsch. Med. Wochensh.*, No. 46, 1886; see also, for similar cases, *New York Med. Rec.*, vol. ii., 1886; and *La Pratique Med.*, Jan., 1891). On the other hand, cocaine has been very largely used as a local application without the production of symptoms;

nevertheless, the employment of any large quantity locally is not safe: especially have cases been reported of violent poisoning by injection into the urethra, so that such application is, I believe, at present practised by few, if any, surgeons. Probably it is not safe to apply more than three-quarters of a grain of cocaine at a time to any mucous membrane.

TROPACOCAINE.—BENZOYL-TROPEIN.

This alkaloid was isolated by Giesel from the narrow-leaved coca-plant of Java. It is obtained as an oily liquid, which solidifies in radiating crystals, and is soluble in chloroform, ether, or benzin. It has been physiologically studied by Dr. Arthur P. Chadbourne, who finds that locally it acts in a manner similar to cocaine, without, however, causing ischæmia or congestion of the mucous membrane with which it is brought in contact. It was found by Chadbourne to be only half as toxic as cocaine. In lower mammals it produces in sufficient dose loss of co-ordination, followed by violent convulsions, disturbances of the respiration, coma, and death by centric asphyxia. The convulsions are of cerebral origin. Upon the circulation the drug seems to have only a comparatively feeble influence, causing, however, when in sufficient amount, a steady fall in the arterial pressure. The temperature usually begins to rise before the convulsion, and has been noted as high as 4° C. above the norm. Tropacocaine has been used in the ophthalmological clinic of Professor Schweigger with asserted excellent results as a local anæsthetic. Anæsthesia is said to come on and disappear more quickly than with cocaine, sensation being suspended in less than half a minute after the application of a three-per-cent. solution. Mydriasis is said by Chadbourne to be usually absent, never very pronounced.

FAMILY V.—EXCITO-MOTORS.

In this class are included such drugs as increase the reflex activity of the spinal centres and thereby give rise to disturbance of motility. The only representatives of the class used by the practitioner of medicine are those drugs which contain strychnine as their active principle.

NUX VOMICA—NUX VOMICA. U.S.

The seeds of *Strychnos Nux-vomica*, a middle-sized tree growing in the East Indies, whence the drug enters commerce. They are circular, nearly flat disks, a little less than an inch in diameter, covered with very short, satin-like, grayish hairs; internally they are tough and horny, and are possessed of an intensely bitter taste. They contain two alkaloids,—strychnine and brucine,—existing in combination with an acid, the so-called *igasuric* of Pelletier and Caventou, which, according to Husemann, is identical with malic acid. *Brucine*, which, unlike strychnine, is not officinal, is readily recognized by the following test. When concentrated nitric acid is added to it, a beautiful scarlet or blood-red color is developed, which becomes yellowish-red, and, by warming, yellow; if to this yellow solution, somewhat diluted, some chloride of tin or sulphuret of ammonium be added, it will become a beautiful reddish-violet. Physiologically and therapeutically this alkaloid is similar to, but weaker than, strychnine.

The U.S. Pharmacopœia recognizes the *extract* (*Extractum Nucis Vomicae*), of which the dose is one-fourth of a grain, equivalent to about one-twenty-seventh of a grain of total alkaloids; the *tincture* (*Tinctura Nucis Vomicae*), of which ten minims represent one-thirty-fifth of a grain of total alkaloids, so that the dose may be set down as from ten to fifteen minims, fifteen to twenty-five drops; and the *fluid extract* (*Extractum Nucis Vomicae Fluidum*), which is required to assay one and one-half grammes of total alkaloids in one hundred cubic centimetres, which gives a strength of fourteen-hundredths of a grain of alkaloid to the minim; thus, three minims equal about one-twenty-fifth of a grain of alkaloids. It is usually estimated that strychnine constitutes about forty per cent. of the alkaloids.

STRYCHNINA. U.S.

As kept in the shops, strychnine is a grayish-white powder, but by slow crystallization from its alcoholic solution it may be obtained in

octahedral or quadrilateral prisms. It is soluble in about seven thousand parts of cold water; in two thousand parts of boiling water; very sparingly soluble in absolute alcohol, ether, and benzin; freely soluble in boiling official alcohol, from which it separates on cooling. It is so bitter that it will impart a very intense bitter taste to twenty thousand times its weight of water.

Strychnine yields a very pronounced violet color with many oxidizing agents. The one most ordinarily employed is a mixture of concentrated sulphuric acid and bichromate of potassium (*Otto's test*). According to Dr. Guy, the test is most delicate if the alkaloid be dissolved in a little concentrated sulphuric acid on a plate, and the bichromate added to it, when a bluish and then violet-purplish color is developed, passing finally into a dirty green. *Davy's test* consists in the substitution of a crystal of red prussiate of potassium for the bichromate. *Marchand* uses the peroxide of lead; in this case the sulphuric acid should contain one per cent. of nitric acid. Drs. Vrij and Van der Burg say that these tests are about equally sensitive, and are capable of revealing the one-sixty-thousandth of a grain of the alkaloid. Either the chlorate or the permanganate of potassium may be used instead of the bichromate; indeed, Dr. Guy claims that the permanganate is preferable to the latter. If the strychnine be in quantity, it may be dissolved in very dilute sulphuric acid, and solution of bichromate of potassium be added, when golden-red needle-like crystals of the chromate of strychnine will separate. These dissolve, with the production of a beautiful blue color, in concentrated sulphuric acid. F. L. Sonnenschein (*Vierteljahresschrift für Prakt. Pharmacie*, 1871) says that if strychnine be dissolved in a strong solution of the sulphate of sesquioxide of cerium a beautiful color is induced, which generally passes into a cherry-red, and so persists for several days. Dr. Filchol's test (*Lancet*, April, 1872) consists in the addition of solution of chloride of gold, and the testing of the precipitate by *Otto's* method. The *physiological test* for strychnine is a very sensitive one. In it a fragment of the suspected extract, dissolved in a little acidulated water, is thrown into the cellular tissue of a small frog, which should afterwards be allowed to swim about freely, so that its unconstrained movements can be watched.

PHYSIOLOGICAL ACTION.—Strychnine acts in the same way upon almost all animals. According to Leube (*Reichert's Archiv für Anat.*, 1867, p. 630), however, it takes ten times as much to kill chickens as it does to kill other birds, weight for weight; and among mammals the guinea-pig is very insensitive to it. It has also recently been asserted that on some monkeys it has very little influence (*Boston Med. and Surg. Journ.*, 1872). Its local action is that of a slight irritant.*

* For an elaborate memoir on the effect of age on the action of strychnine, see *Arch. f. Ges. Physiol.*, 1884, xxiv. 530. It is affirmed that very young animals require very large doses

When taken in quantities just sufficient to produce sensible physiological effects, strychnine in man induces a feeling of restlessness, perhaps accompanied by tremblings in the limbs and some stiffness in the neck and jaws. When a somewhat larger amount has been given, there may be general muscular twitchings and startings, with stiffness and stricture of the throat and chest; formications or other abnormal sensations under the skin may or may not be present. After poisonous doses the symptoms come on usually in from fifteen to twenty minutes, rarely after the hour, with great suddenness; sometimes the convulsions are preceded by partial spasms of the muscles of the extremities, but more often the patient is suddenly thrown down by a general tetanic spasm. In this the body is bent backwards and rests upon the heels and the head, in a condition of profound opisthotonos; the legs are rigidly extended and the feet everted; the arms bent and the hands clenched; the eyes staring, wide open; the corners of the mouth often drawn up so as to produce the *risus sardonius*. The senses are often sharpened, but ringing in the ears and dimness of vision may be induced if the fits are severe. The face is at first pale, but, if the fit be sufficiently severe and protracted, it becomes livid from the interference with respiration. Consciousness is not affected, unless when asphyxia becomes so pronounced as to threaten death; in such cases sometimes a period of insensibility precedes dissolution, but generally the intellect is clear to the moment of death. The muscles of the jaw are usually the last in the body to be affected, but trismus finally comes on in severe cases. I have seen death occur in this first convulsion in animals; but Tardieu states that he knows of no such instance in man (compare case of Dr. Demme, *Syd. Soc. Year-Book*, 1865-66, p. 441). After a time the paroxysm is at an end, the jaw drops, the muscles relax, and a period of calm comes on, to be succeeded by a second convulsion like the first. These convulsions are excited by the slightest touch, by a draught or breath of air, even by a loud sound; but a firm grasp or hard rubbing of the muscles is frequently grateful. A slight rigidity is sometimes manifest between the paroxysms, but no marked stiffness. The spasms are generally, but not always, very painful. There are often erections of the penis, and the feces and urine may be passed involuntarily. If the case terminates favorably, the convulsions gradually lessen in intensity, and fade away, leaving the patient exhausted, with a sore, tired feeling in the muscles. After death, post-mortem rigidity is developed very quickly. Autopsies have revealed nothing but the usual congestive lesions of death from asphyxia, and at times, indications of spinal hyperæmia.

to kill. This is confirmed by Behrend Lau (Elmhorn, *Inaug. Diss.*, 1886), and is in accord with the observations made in the out-patient department of the Hospital of the University of Pennsylvania by Dr. J. H. Musser, who finds that age very greatly increases the susceptibility to nut vomica.

In regard to the method in which strychnine produces the above symptoms, it is obvious that the alkaloid is primarily absorbed; and experimental proof seems so superfluous that I will only mention the fact that Masing has found the strychnine in the blood.

It is very plain that convulsions can be produced by a drug in only five ways: first, they may be epileptiform,—i.e., cerebral; second, they may conceivably be due to a stimulation of the peripheral ends of the motor nerves; third, they may conceivably be caused by irritation of the peripheral ends of the sensory nerves; fourth, they may be muscular,—i.e., due to a direct action on the muscles; fifth, they may be spinal.

That the convulsions of strychnine-poisoning are not cerebral* is proved by the fact which has been frequently noted, and which I have confirmed, that they are not affected by section of the cord, or, at least, are only so far affected as to be more severe in those portions of the body removed from the cerebral influence. That they are not due to irritation of the peripheral motor nerves and are not muscular is proved by the experiment of Valentin (*Pathologie der Nerven*, p. 327, Leipsic, 1864), who found that the injection of a solution of strychnine through the blood-vessels of the amputated leg of a frog had no influence upon the muscles. A very beautiful experiment of Brown-Séquard (*Comptes-Rendus*, 1849) confirms this, and also demonstrates that the convulsions do not arise from hyper-excitability of the peripheral afferent nerves. The observer last mentioned found that when the spinal cord was cut just below the origin of the nerves supplying the fore legs of a frog, and all the blood-vessels going to the lower section of the cord were also severed so as to isolate the latter, on the exhibition of strychnine convulsions occurred in the anterior part of the body, while in the posterior segment quiet and a normal reflex activity were maintained, although the blood was carrying the poison to every part of it except the spinal cord. The philosophy of this is evident. The anterior section of the cord, receiving the poison, gave rise to convulsions; the posterior section, receiving no poison, maintained its usual status.

This experiment of Brown-Séquard has been repeated a great number of times by MM. Martin-Magron and Buisson (*Journ. de la Physiol.*, 1860, t. iii. p. 130) with similar results, excepting that in some very rare instances slight convulsions were induced in the posterior portion of the body. These exceptional phenomena appear to have been due simply to a minute portion of the poison reaching the spine by imbibition, since, when by an operative procedure not necessary here to detail (*loc. cit.*, p. 131) the posterior section of the cord was completely isolated and access of the poison by diffusion rendered impossible, spasms never occurred in the posterior part of the body.

* Biernacki is stated to have determined that the psycho-motor zone of the cerebral cortex is in the rabbit rendered less sensitive by strychnine, although he himself is uncertain whether this is due to a direct or to an indirect action. (*Hoffmann and Schwalbe*, 1890, p. 123.)

Strychnic convulsions must be spinal, because they do not arise in any of the other possible methods. This conclusion is abundantly confirmed by direct experiment. Thus, Van Deen (*Physiol. de la Moelle épinière*) and Valentin (*loc. cit.*, p. 329) have shown that when the alkaloid is placed upon the spinal cord, and allowed slowly to diffuse itself, the usual convulsions occur, but are at first confined to those muscles whose nerves have their origin near the point of application, and afterwards spread from muscle to muscle as the poison creeps through the cord. Dr. A. J. Spence (*Edinburgh Med. Journ.*, July, 1866) has performed similar experiments, with similar results. He first bisected the apex of a frog's heart so as to allow all the blood to drain from the body, and then, cutting through the cranium, laid a little piece of aux vomica upon the brain so that the poison would diffuse down through the spinal cord. The result was that first the muscles of the throat, then those of the fore legs, and so on in regular order, were affected.*

Cerebrum.—So far as our present knowledge goes, strychnine has little or no influence upon the cerebral cortical centres. The stimulation of the special senses sometimes seen in the beginning of strychnine-poisoning is probably, though not certainly, peripheral in its origin; and consciousness is probably never directly affected by the drug. Biernacki has found that during strychnine-poisoning the psycho-motor centres of the brain are in the rabbit less susceptible to stimulation than in the normal animal, but is probably correct in his conclusions that this loss of sensibility is not due to any direct influence upon the cerebral cortex (*Therap. Monat.*, iv., 1890).

Spinal Cord.—Claude Bernard (*Leçons sur les Substances toxiques*, Paris) has denied that strychnine produces excitation of the spinal motor centres, because when all the posterior nerve-roots are cut, no convulsions occur, whereas if a single afferent root be allowed to remain, irritation of its peripheral fibrille will cause general tetanic spasms. Allowing the truth of his experimental fact, his deduction certainly is not warrantable.† The non-occurrence of convulsions may depend upon the fact that the reflex motor ganglionic cells are incapable of originating an impulse, and in strychnine-poisoning are simply in such a condition of over-excitability as renders them exceedingly sensitive to slight irritations and causes them to respond most enor-

* Some of the phenomena stated by Dr. Spence to have occurred are at present very difficult to explain. Thus, he noted that as the poison travelled down the cord there was a time when irritation of the fore feet caused only spasm in them; later in the experiment, irritation of the front feet caused spasm of both the front and hind feet, although irritation of the latter did not produce other than normal reflex movements; later still in the poisoning came a stage when irritation of the front legs was powerless to cause spasm in the hind legs, although irritation of the latter would now cause spasm in the former.

† Dr. Spitzka (*Chicago Journ. Ment. and Nerv. Dis.*, vi. 216) affirms that a frog with all the sensory nerve-roots and the nerves of special sense divided still develops tetanus when strychnine is administered. It would be strange if so noted a physiologist as Claude Bernard should make so gross an error in experimentation.

getically to peripheral impulses so feeble as not to be felt in health. That the motor centres are acted upon by strychnine is proved not only by the experiments that have been already detailed, but also by the following ingenious one of Van Deen (*Physiol. de la Moelle épinière*). This investigator removed the viscera, vessels, etc., from a frog, so as to leave nothing below the second cervical vertebra but the bones, nerves, and muscles; then, opening the spinal cord in the region of the third vertebra, he cut entirely through the anterior columns of the cord, and finally divided all the tissues, so that the anterior portion of the frog was connected with the posterior solely by the posterior columns of the cord. When one or two drops of a solution of strychnine were placed in the mouth of the prepared butrachian, tetanus, confined to the anterior segment of the body, was developed; and it was also found that while irritation of the posterior feet caused in them only ordinary reflex movements, in the front legs tetanic spasms were simultaneously induced. It appears to me proved, by the evidence adduced in this and the preceding paragraphs that strychnine is a powerful stimulant to the cells of the spinal cord; including in this term the whole spinal tract up to the pons Varolii. As shown by Spitzka, and confirmed in my laboratory, enormous doses of strychnine injected into a vein kill almost instantaneously without the production of a spasm. Such doses probably kill the nerve-centres, just as large doses of a cardiac stimulant overwhelm and paralyze the viscus.

Motor Nerves.—The action of strychnine upon the motor nerves has been a subject of considerable controversy. That the convulsions occur independently of any such influence, if it exists, has been already shown. After death from strychnine, the functions of the motor nerves are always found to be more or less impaired, so that galvanization of the nerve-trunk produces either only very feeble contractions in the tributary muscles, or else none at all.* Of this fact there would seem to be no doubt; it has been attested on the evidence of personal experiment by many observers, among whom are Matteucci (*Traité des Phénomènes électro-physiologiques*, Paris, 1844), Moreau (*Comptes-Rendus*

* Dr. W. H. Klapp affirms that he has found in thirty-seven experiments the motor nerve unimpaired in the frog after death from strychnine (*Journ. Ment. and Nerv. Dis.*, Oct. 1876). It is inconceivable that all previous observers should be mistaken in their observations. It has been suggested that the effects upon the motor nerves usually attributed to strychnine have been due to brucine contaminating it; and Dr. Robert P. Robins (*Phil. Med. Times*, ix. 229) has found nerves insensitive in animals killed with brucine,—a result in accord with the experiments made upon *Rana esculenta* by Professor Mounier, of Geneva. Dr. Lautenbach has shown, however, that chemically pure strychnine impairs the function of the motor nerves, and that in some frogs, or under some life-conditions, brucine has no effect upon the nerves. It would seem that both of these alkaloids impair the functions of the motor nerves, but that under certain conditions the nerves have greater resisting powers than usual. It is probably different states of health rather than different species of frogs, as believed by Lautenbach, that cause the diversity of results. The possibility of a stray galvanic current being directly transmitted by a nerve to a muscle must also not be forgotten.

Soc. de Biol., 1855), M. Ambrosoli (*Gazette Médicale*, 1857, p. 525), Wittich (*Bericht d. Fortschritte d. Anat.*, 1857, p. 434), Kölliker (*Virchow's Archiv*, Bd. x. p. 239, 1856), and Vulpian (*Archives de Physiologie*, Nov. 1870, p. 125). Now, it is evident that this absence of response may be due to loss of functional power in either muscle or nerve. Sometimes the muscle may be at fault; but, as Matteucci (*loc. cit.*) insists, and as has been noted by many observers, not rarely—indeed, most generally—in the frog galvanization of the nerve fails to elicit response, although the muscle preserves its irritability. M. Ch. Richet (*Comptes-Rendus*, xci. 131) determined experimentally that if active artificial respiration be maintained, enormous doses of strychnine injected into the vein of a mammal paralyze the motor nerves. M. Vulpian (*Ibid.*, xciv. 556) and Professor E. T. Reichert (*Therap. Gaz.*, March, 1892) have confirmed these results: so that it may be considered proved that in the warm—as well as in the cold-blooded animals strychnine depresses directly the motor nerves.

It having been proved that the functional power of the motor nerves is destroyed in strychnine-poisoning, the question arises, Is this destruction a direct action of the poison, or is it simply the exhaustion of over-use, due to the intense activity of the nerve during the stage of spasm?

It cannot be gainsaid that the power of the nerve is lessened by the strain upon it during the convulsions; and Kölliker concludes (*Virchow's Archiv*, Bd. x., 1856) that this is the sole cause of the nerve-paralysis, because when he cut the sciatic nerve of a frog and exhibited strychnine the divided nerve would respond to galvanic stimuli after all functional power had been lost in the nerve whose connection with the centres was intact. Granting the experimental fact, it would only prove that contact of the poison was not the sole cause of the motor-nerve paralysis, as it is plain that although both nerves suffered this contact, yet the uninjured one suffered it plus exhaustion from excessive use. The conclusion is, moreover, opposed by the fact attested by Vulpian (*Archives de Physiologie*, 1870, t. iii. p. 120) and other observers, that an enormous dose of strychnine kills the frog without the induction of spasms by general paralysis, with total loss of power in the nerve-trunks. Evidently in such case the action of the poison on the nerves must be direct.

MM. Martin-Magron and Buisson (*Journ. de la Physiol.*, 1860, t. iii. p. 342), and also Vulpian (*loc. cit.*, p. 126), have proven that if the sciatic nerve of a frog be cut and a sufficiently large dose of the strychnine administered, the divided sciatic loses its irritability, although, unless the dose has been very large, not so soon as does its fellow. Martin-Magron and Buisson also tied all the tissues of a frog's leg except the nerve, and then, on exhibiting strychnine, found that convulsions ceased in the poisoned much sooner than in the non-poisoned leg, and that at a certain time irritations of the poisoned foot would induce tetanic spasms only

in the *non-poisoned member*,—proof that the afferent nerve-fibres of the poisoned leg were not affected, and that the motor nerves were paralyzed wherever the poison had access to them, and that to this, not to spinal exhaustion, was due the general paralysis. Vulpian has confirmed these experiments, which appear to prove that strychnine in very large doses paralyzes the efferent but not the afferent nerves, and that the collapse of strychnine-poisoning in the frog is largely due to the affection of the motor trunks, and not to exhaustion of the spinal cord. E. Poulsson (*Arch. Exper. Path. u. Pharm.*, Bd. xxvi.) has also corroborated this, and has further shown how contrary results may be explained by the fact that the nerves in the *Rana esculenta* remarkably resist the direct depressing action of strychnine. That which Fraser has discovered for atropine, Vulpian (*loc. cit.*, p. 128) has found for strychnine: namely, that in the frog after a time,—from some hours to two days,—if the dose has been of the right size, the strychnic paralysis passes off, the motor nerves regaining their power, and the convulsions reappearing, to continue hours or days.

The evidence seems to me complete, and it must be considered proven, that strychnine exerts a direct paralyzing influence upon the motor nerves both in cold- and warm-blooded animals. It is, however, probable, as is insisted upon by Poulsson, that the spinal cord is also paralyzed, because in certain frogs, and also in mammals, the paralysis appears to be complete at a time when the motor nerves are still capable of responding to stimuli.

Circulation.—Strychnine has a very decided influence upon the circulation. Drs. Richter (*Zeitschrift f. ration. Med.*, 1863, xviii.), Mayer (*Med. Jahrb. d. k. k. Gesellschaft der Aerzte zu Wien*, 1872, p. 112), Schlosinger (*Ibid.*, 1874), and Klapp (*Journ. Ment. Dis.*, Oct. 1878) have all found that a decided rise of arterial pressure comes on before or about the time of the first convulsion.* The rise is not due to the convulsion or to the interruption of the circulation, as it occurs in curarized animals in which artificial respiration is maintained.† Both Richter and Mayer affirm that the small arteries can be seen to contract under the influence of the strychnine, and conclude that the rise of the pressure

* Professor Relebert states that in the dog very commonly, but not always, the rise of pressure produced by strychnine is preceded by a fall of pressure accompanied by a lessening in the frequency of the pulse, and that he has not been able to determine the way in which this primary fall of pressure is produced. As, however, he has found that this primary fall is always "entirely set aside by curare," it is evident that the fall is produced by some indirect method, and is not a characteristic action of the strychnine, nor yet the result of any direct influence upon the vaso-motor centres.

† In the experiments of J. Denys (*Archiv f. Exper. Path. Pharm.*, Bd. xx. S. 306) the rise of the blood pressure was found to be much more pronounced after small doses of strychnine in curarized animals than in the normal animal. In the normal animal after spasms there was a very pronounced fall in the arterial pressure, confirmed by Reichert. It is probable that during the convulsion the vaso-motor centre shares in the general nervous discharge, and that the circulation partakes in the relaxation and exhaustion which follow a tetanic fit.

is due to vaso-motor spasm. Mayer also noted that after paralysis of the dominant vaso-motor centres by section of the cord, strychnine produced no rise of the arterial pressure, or if any was caused it was very slight. Both Klapp and Professor Reichert (*Therap. Gaz.*, April, 1892)* have confirmed this.

It has been shown by the experiments of Klapp and Reichert that the primary stimulation of the vaso-motor centres by strychnine is followed by fall of arterial pressure and vaso-motor palsy; also that very large doses produce an immediate depression of the vaso-motor centres and fall of arterial pressure.

There is some apparent conflict of testimony in regard to the influence of strychnine upon the inhibitory cardiac nervous system. Dr. Carl Heinemann, who has investigated at some length (*Virchow's Archiv*, Bd. xxxiii. p. 394) the influence of the drug upon the heart of the frog, finds that large doses cause diminished frequency of the cardiac movements, with diastolic pauses.† According to his experiments, these phenomena are not due to stimulation of the inhibitory nerves, since they occur after section of the vagi (p. 403), nor are the peripheral vagi paralyzed, since galvanization of one of these nerves causes immediate diastolic cardiac arrest (p. 406). Mayer (*loc. cit.*) has also found that

* A different experimental result has, however, been reached by Schlesinger (*loc. cit.*). This investigator found that the rise after the division of the cord both absolutely and relatively exceeds that produced in the normal animal. It is worthy of note that in three of the fifty experiments made by Schlesinger upon rabbits the strychnine failed to elevate the pressure after section upon the cord. Schlesinger explains the apparently opposite results reached by himself and by Mayer by the fact that the latter investigator employed dogs, and further states that in six experiments made by himself on dogs he four times obtained results similar to those of Mayer. Klapp experimented upon the cat, dividing not only the spinal cord, but also all the cardiac nerves of the neck. Under these circumstances no rise of pressure followed the injection of the strychnine. I have no doubt that the explanation given by Klapp of the peculiar results obtained by Schlesinger—namely, that it was because he failed to make a perfect section of the cord—is correct. Schlesinger also found that in the strychnized animal stimulation of a sensitive nerve produced rise of pressure by vaso-motor spasm even after section of the spinal cord. The explanation that he offers of this is that in the normal animal the peripheral impulse can only reach the vaso-motor nerves by first going to the dominant centres in the medulla, but that strychnine so alters the functional conditions of the spinal cord as to allow the peripheral impulses to bring a response by acting upon the local vaso-motor centres in the cord,—that is, by causing a general vaso-motor spasm. The correct interpretation of this alleged discovery of Schlesinger is probably that he obtained a rise of pressure because he had failed entirely to sever the spinal cord. I have found myself, experimentally, that a few fibres of the spinal cord may be sufficient to convey irritations of nerves to the sensory cord, though these irritations are apparently unfelt by the animal after an almost complete section of the cord. It must, however, be acknowledged that although in the majority of Klapp's experiments no rise of pressure occurred in the strychnized animal after section of the spinal cord upon galvanization of a sensitive nerve, in a few instances such rise did happen, probably because a few fibres of the spinal cord were left uncut.

† For the paper of Bruntton and Cash showing that strychnine increases the "refractory period" of the isolated frog's heart, see *Proc. Roy. Soc.*, 1883. A consideration of this memoir would require an elaborate discussion of the minute points of cardiac physiology, and, as it would throw at present no light upon the practical use of the drug, is not entered upon.

the peripheral vagus is not paralyzed, since he could suspend the action of the heart in the poisoned animal by galvanization of the par vagum. Klapp has also reached results confirmatory of those of Heinemann. On the other hand, Martin-Magron and Buisson* affirm (*loc. cit.*, p. 352) that in all of very many experiments, after a greater or less length of time, the pneumogastrics lost their power of transmitting an impulse.

The discordance in these results seems to be explainable on the supposition that the differences are the result of the use of different doses, since Professor E. T. Reichert has found that the early effect of strychnine is to stimulate the peripheral inhibitory apparatus of the heart, but that if the dose have been sufficient this stimulation is followed by pronounced depression or even complete paralysis. According to the same investigator, when the salt of strychnine is injected intravenously into the dog there is, first, a transient increase of the pulse-rate, due to the immediate overwhelming action of the undistributed strychnine upon the inhibitory apparatus of the heart; second, a lessening of the pulse-rate, due to slight stimulation of the pneumogastric endings; third, a marked increase in the pulse-rate, due to pneumogastric depression; and, finally, a decrease in the pulse-rate, the result of an influence upon the heart-muscle or its ganglia. There is reason for believing that small doses of strychnine have a stimulating influence upon the heart itself. Dr. I. Steiner has found the action of strychnine much more marked when it is placed upon the posterior than when it is placed upon the anterior face of the frog's heart, also that the strychnine acts much more promptly and severely upon the separated sinus venosus than upon the ventricles or the auricles, and hence concludes that the strychnine acts especially upon the ganglia of the sinus. His experiments and conclusions have been confirmed by Klapp, and are probably correct.

Upon blood outside of the body strychnine has probably some action. Harley found that blood shaken for twenty-four hours with air contained 11.33 parts of oxygen and 5.96 parts of carbonic acid; while blood treated in a precisely similar manner, except in the addition of strychnine, yielded 17.80 parts of oxygen and 2.73 parts of carbonic acid. He concludes from this that strychnine arrests oxidation in the body; but the deduction seems to me out of all proportion to the fact. Dr. Maurel has found that five centigrammes of the sulphate of strychnine is sufficient immediately to kill the leucocytes in one hundred grammes of blood, and claims that in poisoning by the strychnine sulphate the death of the leucocytes and of the animals took place at the same time (*Bull. Gén. Therap.*, Mars, 1892).

Respiration.—In human strychnine-poisoning the rate of the respiration is often, but not always, increased, and in a series of experi-

* That the different results reached by observers are not due to the use of different animals is evident, since, although Mayer used hounds, both Heinemann and Klapp employed the same animals as did Martin-Magron and Buisson,—viz., frogs.

ments made upon dogs. Professor Reichert found that sometimes the respiratory rate was increased, sometimes it was decreased, and reached the conclusion that strychnine is not a respiratory stimulant. The effect of the drug upon the respiratory rate is not, however, any criterion as to the action of the drug upon the respiratory function, and in a series of very careful experiments, in which the respiratory air-movement was measured, I found that the injection of strychnine produced in the dog an extraordinary increase in the respiratory air-movement, which increase was never less than seventy-five per cent., and sometimes rose to three hundred per cent. A second series of experiments made on chloralized dogs reached the same conclusion, which is, further, in accord with clinical experience; and there can be no doubt that the alkaloid strychnine is among the most certain of the respiratory stimulants and that its action is direct and centric (*Journ. Physiol.*, 1892). Dr. Anton Obermeier (*Inaug. Dissert.*, Erlangen, 1891) has, in a long series of experiments, found that small doses of strychnine produce in the rabbit no distinct alteration in the elimination of carbonic acid, but that after large doses there is a rise of the animal temperature and a very noticeable increase in the throwing off of carbonic acid.

Eye.—The effect of strychnine upon the normal eye has been studied by V. Hippel (*Wirkung des Strychnins auf die normale und kranke Augen*, Berlin, 1873) and Cohn (*Wiener Med. Wochenschrift*, Nos. 42, 47, 1873), with rather different results. They both, however, found the sharpness of vision increased.*

Absorption and Elimination.—According to the researches of R. W. Lovett (*Journ. Physiology*, ix.), after its absorption, which is immediate, strychnine especially accumulates in the spinal cord; but Ipsen claims that it is to be found in all the organs in direct proportion to the amount of blood going to them. Grandval and Sajoux have found the alkaloid in the brain after the therapeutic use of it (*Union Med. du Nord-Est*, May, 1892). Schiff and Lautenbach believe that they have proven that the alkaloid is destroyed, at least in part, in the liver; a conclusion which is strongly combated by Chouppe and Pinet (*Compt. Rend.*, cv., 1887), and is very doubtful. It is certain that strychnine escapes to some extent unchanged, as it has been found in the urine by Peter von Rautenfeld (*Inaug. Dissert.*, Dorpat, 1884), by Wormley (*Micro-Chemistry*, 2d ed.), by Schauenstein, by Kratter (*Wien. Med. Wochenschr.*, 1882), and by Dixon Mann (*Med. Chron.*, vol. x., 1889). Its elimination is prompt and rapid, as Ipsen claims that it can be found in the urine five minutes after its absorption, and others have detected it in the urine half an hour after its exhibition; and in various poisoning cases, fatal within two hours, it has been found in the urine. Kratter and Mann believe that they have proven that the elimination is com-

* For the details of their studies the reader is referred to the original paper, or to the abstract in the *Boston Med. and Surg. Journ.*, p. 473, 1874.

plete within forty-eight hours. According to P. C. Plugge (*Archiv der Pharm.*, 1883), a portion of the alkaloid is converted into *strychnic acid*.

Summary.—In small therapeutic dose strychnine produces a little apparent effect, but acts as a powerful bitter, increasing at the same time the general tone of the body. After large therapeutic doses there is probably a pronounced general stimulation and increase of bodily tone. The fullest permissible doses stimulate very powerfully the respiratory centres, and also increase blood-pressure by stimulation of the vaso-motor centres, and probably also have some stimulant influence upon the heart itself, as well as upon its peripheral inhibitory apparatus. Toxic doses produce violent reflex tetanic convulsions, without loss of consciousness, by causing excessive irritability and excitement of the ganglionic spinal cells, and lower the functional activity of the motor nerve-trunks by producing exhaustion and by a direct paralytic influence: death occurring during a convulsion is due to cramp asphyxia, and is usually immediately preceded by loss of consciousness; death between the convulsions is the result of a paralytic asphyxia, produced in part by an exhaustion, and perhaps also a direct secondary paralysis, of the respiratory centres, and in part by a loss of functional power of the respiratory nerve-trunks. There is also reason for believing that the toxic dose paralyzes the peripheral pneumogastric nerve and greatly depresses the heart itself and the vaso-motor system. The absorption and the elimination of strychnine are rapid, the alkaloid escaping partly in the form of strychnic acid and partly unchanged.

THERAPEUTICS.—Clinical experience shows that strychnine is a powerful bitter, tonic, and stomachic, stimulating digestion and increasing the appetite, a conclusion which has been elaborately confirmed by Dr. S. F. Hamper (*London Med. Recorder*, Feb. 1891), who, using Ewald's test-breakfast, found that the drug increases the volume and digestive power of the gastric juice as well as the movements of the stomach. Strychnine is, however, more than a mere stomachic: clinical experience has shown that it is a most useful tonic when there is general relaxation and loss of nerve-power. A portion of its value arises, it may be, from its action upon the spinal motor nerve-centres; but in all likelihood it influences other portions of the cord, affecting the vaso-motor centres, and most probably also the trophic centres. Be these things as they may, clinical experience has abundantly demonstrated the value of the drug as a tonic in general *functional atony and relaxation*.

Many years ago Trousseau taught that in certain cases of *chorea minor* the strychnine preparations are very valuable, and Professor Morris Benedict (*Wien. Med. Wochens.*, xli., 1891) claims that the remedy is useful against choreic movements. It is not probable that in such cases the strychnine exerts any specific influence. I have experimentally proven that in choreic dogs it greatly increases the activity of the movements; and any good which it may achieve in *chorea minor* is probably due to its tonic powers.

The great influence of strychnine upon the function of voluntary motion early led to its use in cases of *paralysis*, often with the result of doing harm rather than good. Its peculiar physiological action being known, it becomes very evident that it can be useful only when the paralysis is dependent upon, or at least accompanied by, a *depressed state* of the *spinal* or other *motor centres*. Whenever there is *inflammation* or *irritation* of these latter, strychnine may do great injury by increasing such irritation, and must never be employed. Like galvanism, in *hemiplegia* it can do only a very limited amount of good, and should not be exhibited until irritation from the clot has ceased. It is probably useful in all forms of *lead paralysis*, but when the symptoms resemble those of *poliomyelitis*—i.e., a multiple paralysis with rapid wasting of the affected muscles and alterations of the electro-contractility—I have found strychnine pushed to the verge of poisoning extraordinarily efficacious.

Since attention was so signally called to the value of strychnine in *amaurotic* affections by Nagel, of Tübingen, in 1871, numerous observers have published extended series of cases in which it has been used with strangely-varying results. They have for the most part, however, served to verify the favorable results obtained by Nagel (*Die Behandlung der Amaurosen und Amblyopen mit Strychnin*, Tübingen, 1871). His sanguine expectations regarding its use in nerve-atrophy have met with disappointment in the hands of other observers. It is now conceded that in atrophy of the essential nerve-structure little is to be expected from strychnine or any other means. It is most useful in cases which have not yet reached the stage of atrophy, but present slight if any ophthalmoscopic changes. The chalky or greenish-white and cupped nerve-entrance is not always, however, sufficient cause for pronouncing the case hopeless, for these appearances are not always safe indications of the amount of injury done to the axis-cylinders. Its value in amaurosis from abuse of alcohol and of tobacco is undisputed. Also in amblyopia from disuse,—e.g., in strabismus and paresis,—after the parallelism of the visual axes has been restored, under its use normal sharpness of vision is much more rapidly attained. In cases where the ophthalmoscope reveals but slight change in the retina and nerve,—e.g., slight striation of retina around the disk, the margin of which is somewhat obscured, or in disturbances of the anastomotic circulation at the nerve-entrance, with or without diminished sharpness of central vision and contraction of the field,—strychnine is of marked benefit. The distressing headache and giddiness associated with these nerve-troubles which thus manifest themselves in the eye are frequently relieved by the use of strychnine, even though the nerve is quite atrophied and the eye blind. There is much difference of opinion as to the method of its administration, but better results in the hands of most observers follow its hypodermic use. The temple would seem to be a better locality than the arm, as improvement in the corresponding eye has been fre-

quently observed, while its fellow remained as before. It should be given in gradually-increasing doses, being governed by the tolerance of the action of the drug. Commencing with one-thirtieth of a grain, it can usually in a few weeks be carried up to one-tenth or even one-fifth of a grain once or twice daily, these doses causing only a twitching in the calves of the legs, or a slight sense of constriction about the throat, coming on in from ten to fifteen minutes after their administration, and subsiding in the course of an hour or two. It is necessary to maintain the physiological impression to insure the best results.*

Of all the respiratory stimulants, strychnine appears to be the most constant and reliable in its influence. Attention seems to have been first called by Dr. J. M. Fothergill to its practical value in *dyspnœa* dependent upon pulmonic affections, in the treatment of *chronic bronchitis*, in *emphysema*, in *phthisis*. Whenever in *pneumonia* or other disease of the lungs the respiratory function is failing, the remedy is invaluable. In long-standing *bronchitis* or *winter cough*, and in other obstinate pulmonic diseases with dilated right heart, the combination of strychnine and digitalis yields most excellent results. Much advantage may often be derived, especially in feeble subjects, by adding strychnine to ordinary cough mixture.

The value of strychnine in the treatment of the respiratory accidents of *anæsthesia*, which was first pointed out in my address before the Berlin Congress in 1890, is now universally acknowledged. The drug has no less value in other similar acute respiratory poisoning. In these cases, as well as in many cases of disease, the best results are, however, to be obtained not simply by the use of strychnine, but by the use of strychnine in combination with other respiratory stimulants. Thus, I have found in chloralized animals after strychnine had been given almost to the point of producing convulsions, cocaine was capable of still further increasing the respiratory air movement; and I have seen, also, in the sick-room, life apparently saved by the addition of cocaine to the strychnine, which was already being given in as full doses as seemed justifiable.

In *dyspepsia* or *constipation* or *diarrhœa*, connected with atony of the visceral muscular coat, strychnine is a very valuable remedy. In various local paralyses, such as *prolapse of the rectum*, *atonic retention of urine*, *atonic incontinence*, and *loss of voluntary motion* in certain groups of muscles from temporary injury to the supplying nerve or even from so deep-seated a disease as *infantile paralysis*, it is useful. There is reason to believe that it sometimes does good in these cases by influencing the nutrition of the affected muscle or the peripheral nerves; and it should be injected into the affected part.

Strychnine is also a serviceable remedy as a stimulant in cases of mental and physical depression due to prolonged excitement and over-

* This paragraph was written by Dr. E. D. Risley, and is expressive of the results at the University Hospital, where he is chief assistant of the Ophthalmological Clinic.

work. Dr. J. H. Musser (*Therap. Gaz.*, ii. 10) asserts that during the strain of student-life before examination it is especially valuable in preventing the development of *asthenopia*.

TOXICOLOG.—Sufficient has already been said in regard to the general symptoms of strychnine-poisoning. It only remains to discuss the diagnosis.* This is especially important, because strychnine is frequently used criminally, and because not rarely it is impossible for the chemist to detect it after death.

The only disease with which a typical case of strychnine-poisoning seems to be readily confounded is tetanus, in its various forms of idiopathic, traumatic, infantile, and hysterical. Cases of strychnine-poisoning have, however, occurred in which the symptoms have appeared to point towards some cerebral disease or cerebral poisoning. Thus, in the case reported by Mr. Henry Pilkington (*London Lancet*, vol. i., 1893), the patient was found unconscious, surrounded by vomited matters, with excessively uneven pupils and an elevated temperature. After death both lateral ventricles were found to contain clots, and there can be little doubt but that the high arterial pressure during an early convulsion had produced an apoplexy which was the cause of the symptoms and death. It has been asserted that in fatal cases the duration of the attack will always distinguish between natural tetanus and that produced by poison. Dr. Louis Starr, however (*Phila. Med. Times*, iii. 311), reports traumatic tetanus fatal in twelve hours after the first muscular twitchings, and within one hour and a half after the first convulsion; and death from tetanus has occurred fifteen minutes after the reception of the injury (Jaccoud, *Pathologie Interne*, i. 441).

The following table shows, I think, in as clear and brief a manner as possible the differences between traumatic or idiopathic tetanus (No. 1), hysterical tetanus (No. 2),† and strychnic poisoning (No. 3). The references in column No. 3 are to authorities who affirm that the symptoms there given are peculiar to poisoning.

No. 1.	No. 2.	No. 3.
	Commenced with blindness and weakness.	Begins with exaltation and restlessness, the special sense being usually much sharpened; Dimness of vision may in some cases be manifested later, after the development of other symptoms, but even then it is rare.
Muscular symptoms usually commence with pain and stiffness of the back of the neck, sometimes with slight muscular twitchings; come on gradually.	Muscular symptoms commenced with rigidity of the neck, which gradually "crept over the body," affecting the extremities last.	Muscular symptoms develop very rapidly, commencing in the extremities, or the convulsion, when the dose is large, seizes the whole body simultaneously.‡

* A lesion found in one case by Moriz Rosenthal may possibly be characteristic. It is numerous small cross-vents in the heart-muscle, accompanied by small extravasations (*Nervenkrankheiten*, 1870, p. 334).

† Column No. 2 is from an actual case. See trial of Mrs. Wharton, *New York Medical Record*, 1873.

‡ Taylor, *On Poisons*, p. 633. Wormley, *Micro-Chemistry of Poisons*, p. 336.

§ Wormley, p. 636. Stillé, *Therapeutics*, vol. ii. p. 143.

No. 1.

Jaw one of the earliest parts affected; rigidly and persistently set.

Persistent muscular rigidity, very generally with a greater or less degree of permanent opisthotonus, emprosthotonus, pleurosthotonus, or orthotonus.

Consciousness preserved until near death, as in strychnic poisoning.

Draughts, loud noises, etc., produce convulsions, as in strychnic poisoning.

May complain bitterly of pain.

Eyes open, rigidly fixed, during the convulsion.

No. 2.

Jaw rigidly set before a convulsion, and remained so between the paroxysms.

Persistent opisthotonus, and intense rigidity between the convulsions; and after the convulsions had ceased the opisthotonus and intense rigidity lasted for hours.

Consciousness lost as the second convulsion came on, and lost with every other convulsion, the disturbance of consciousness and motility being simultaneous.

Desired to be fanned.

Crying-spells, in which he "sobbed violently," and "cried like a child," alternated with the convulsions.

Eyes closed.

The spasm in leg must have been partial, as the feet were crossed and toes inverted, which could not happen if all the muscles were involved, because the muscles of eversion, being very much the stronger, would of necessity overcome the antagonistic muscles, and the feet be everted.

No. 3.

Jaw the last part of the body to be affected: its muscles relaxed, and, even when during a severe convulsion it is set, it drops as soon as the latter ceases.*

Muscular relaxation (rarely a slight rigidity) between the convulsions, the patient being exhausted and sweating. If recovery occur, the convulsions gradually cease, leaving merely muscular soreness, and sometimes stiffness like that felt after violent exercise.†

Consciousness always preserved during convulsions, except when the latter become so intense that death is imminent from suffocation, in which case sometimes the patient becomes insensible from asphyxia,‡ which comes on during the latter part of a convulsion, and is almost a certain precursor of death.

The slightest "breath of air" produces a convulsion.§

Patient may scream with pain, or may express great apprehensions, but "crying-spells" would appear to be impossible. Eyes stretched wide open.||

Legs stiffly extended, with feet everted,¶ as the spasm affect all the muscles of the leg.

Death from strychnine in man and other mammals mostly occurs in a convulsion, and under these circumstances is undoubtedly due to asphyxia, caused by the unyielding spasmodically-contracted muscles. In frogs, death must occur from other causes, since a frog, as shown by Claude Bernard, will live for days after removal of its lungs, probably by breathing through its skin. The causes of death in the frog are not hard to find when the physiological action of the drug is known. The

lymph and true hearts (Kölliker, *loc. cit.*; Harley, *Lancet*, July, 1856) are very much affected, but the chief factor is no doubt paralysis of the motor nerves. In man, death sometimes occurs not in a paroxysm, but during relaxation, and probably then is the result not only of the exhaustion following effort, but also of the direct action of the poison on the nerves.

Dr. Honigsmann (*Schmidt's Jahrb.*, Bd. cexxiii. p. 21) reports a remarkable case, in which acute inflammation of the kidneys followed strychnine-poisoning.

The minimum fatal dose of strychnine is probably something under half a grain; the latter quantity has several times produced death, once in a man in twenty minutes (*Guy's Hosp. Rep.*, 1865, vol. xi. p. 208); one-third of a grain given at intervals in fractional doses has produced such alarming symptoms as to indicate that in a single dose it might readily destroy life; one one-hundredth of a grain is said to have killed a child three and a half months old (*Pharm. Journ. and Trans.*, viii. 1010); but ten grains (Tschepke, *Deutsche Klinik*, 1861), twenty grains (A. E. Connor, *Ohio Med. Recorder*, 1879, 12), also twenty-two grains (Dr. Geo. Gray, *Brit. Med. Journ.*, 1880, i. 477) taken on a full stomach and retained two hours, have failed to cause death, in each case probably on account of slow absorption.

In treating poisoning by strychnine, a chemical antidote should be at once administered, such as tannic acid, or iodine or one of its soluble salts. As, however, the compounds formed in the stomach by these substances are not permanent, a quick emetic must follow their administration. For the treatment of the symptoms, various substances have been recommended. Aconite, Calabar bean,* tobacco, or their alkaloids, would appear to be indicated as physiologically antidotal. The evidence brought forward by Dr. Haughton and others is not sufficient to establish clearly the especial value of tobacco, and in the experiments of M. Amagat (*Journ. de Thérap.*, 1875) nicotine seemed to have no power in preventing the death of rabbits which had received a fatal dose of strychnia. Further, it is obvious that the use of aconite, or of tobacco, in large doses, is accompanied with grave danger, on account of their influence upon the heart, and we have in bromide of potassium a substance devoid of any such objection, and apparently as complete a physiological antidote to strychnine as are any of the substances above named. The chief question is as to whether the bromide has sufficient power and swiftness of action. In Dr. C. L. Bard's case† (*Phila. Med. Times*, i.), recovery after the ingestion of three grains of the alkaloid, without vomiting, occurred under the exhibition of a half-ounce dose of the potassium salt and "its continued use in smaller doses

* For two cases of recovery very doubtfully attributable to Calabar bean, see *Ohio Med. Recorder*, iv. 154.

† For other successful cases, see *New Remedies*, vol. ii. p. 255; also, *Chicago Medical Examiner*, 1879, xxix. 280.

for an hour or so." The symptoms were as intense as was consistent with life, but general relaxation was produced in thirty minutes after the administration of the counter-poison.

Chloral was stated by Liebreich, its therapeutic discoverer, to be antagonistic to strychnine, and it undoubtedly is so in a measure; but M. Orr (*Gazette Médicale*, July 6, 1872) stated to the French Academy that he had experimentally proved that the dose of chloral which Liebreich had relied on as being mortal to rabbits was very often not so, that the same was true of strychnine, and that consequently the investigation of Liebreich was not to be relied on as proving the respective antidotal powers of the drugs; and, further, that experiments had shown him that if a certainly-fatal dose of chloral were given to a rabbit, the hypodermic injection of strychnine did not affect the result, but that his own researches had not gone far enough to establish the exact relations of the drugs. Professor Bennett (*Brit. Med. Journ.*, vol. ii., 1874) has made an elaborate study, which agrees with the experiments of Orr in showing the non-efficiency of strychnine in chloral-poisoning, but also proves that chloral is of great value in poisoning by the alkaloid. Out of twenty-one rabbits which had received much more than the minimum fatal dose of strychnine (gr. $\frac{1}{16}$ to the pound), fifteen were saved by the use of chloral, and a few days later were killed in from ten to twenty minutes by a repetition of the original doses of strychnine. Dr. Bennett found that the chloral administered after the supervention of convulsions had less effect in saving life in direct proportion to the length of time between its administration and that of the poison. Professor Husemann (*Arch. f. Exper. Path. und Therap.*, x.) found it possible to prevent death by chloral in rabbits which had received five or even six times the minimum fatal dose of the alkaloid. In various cases recovery from the effects of large doses of strychnine (four grains, *Edinb. Med. Journ.*, April, 1875; six grains, *Arch. Gén. de Med.*, 1883, l. 74, where also numerous cases may be found) has been brought about by the use of chloral, which must be at present considered a standard remedy in strychnine-poisoning. Alcohol has been strongly recommended by some authorities (Amagat, Stacchini) as antidotal; and when the great muscular relaxation of drunkenness is remembered, it seems very probable that the commendation has some basis. Professor Husemann (*loc. cit.*) has, however, shown that alcohol can scarcely be looked upon as a real antagonist to the alkaloid.

The best treatment of strychnine-poisoning is apparently to be found in the conjoint use of chloral and the bromide of potassium, with, when convulsions are very threatening, inhalations of nitrite of amyl, ether, or even chloroform. Half an ounce of the bromide with half a drachm to a drachm of chloral may be given at once in a severe case; and every twenty minutes afterwards, if necessary, two drachms of the first and fifteen grains of the second remedy.

In some cases artificial respiration might possibly be of service. It

is evident that the convulsed muscles will often resist such efforts as are usually made to force air into the lungs of man as successfully as they do the unassisted struggles of nature; and Harley states that he has found artificial respiration of no use whatever in animals. On the other hand, Leube (*Arch. Anat. u. Physiol.*, 1867), in an apparently very careful series of experiments, found that artificial respiration has great influence in saving or prolonging life, according to the amount of the poison ingested. In his experiments, the dose which ordinarily produced convulsions did not do this so long as artificial respiration was kept up; and the "lethal dose" did not kill if artificial respiration was maintained for four hours, although opisthotonos was induced in some cases. Jocheisohn only succeeded in prolonging life (*Rosbach's Untersuchungen*, i. 92), but Rosenthal, according to Husemann, obtained similar results to Leube, and M. Schiff (*Schmidt's Jahrbücher*, Bd. cxli. p. 43) has, in a series of experiments, corroborated in the main facts the results of the German investigators, although disagreeing with them in minor particulars. He found that animals in which forcible artificial respiration was maintained survived doses much larger than those ordinarily fatal. The artificial respiration was performed by inserting a canula into the trachea and filling the lungs by force. Klapp also found artificial respiration of service. None of the ordinary methods of artificial respiration in man are, however, sufficiently powerful to be of any value.

ADMINISTRATION.—As a tonic, strychnine may be given in pill; but when it is desired to push it until its physiological effects are manifested, as in some cases of *palsy*, it should be always administered as the sulphate in solution, because death has occurred from an irregularity in the solution of the pills in the alimentary canal and the consequent simultaneous letting loose of a large amount of the alkaloid. There is no proof of a cumulative action of this alkaloid when given as above directed. The dose of strychnine and its salts as a bitter tonic is from one-twentieth to one-thirtieth of a grain. In nervous diseases and other affections when pronounced influence is necessary, the dose should be gradually increased until muscular twitching, stiffness of the neck or legs, or other symptoms are manifested. Whenever a rapid action of strychnine is desired, as in the accidents of anæsthesia, the sulphate should be given hypodermically; and in many cases of palsy, especially with trophic changes in the muscles, the best effect seems to be obtained by injecting the strychnine salt directly into the diseased muscle. If proper antiseptic precaution be taken, hypodermic injections may be made without fear of serious local irritation.

STRYCHNINÆ SULPHAS, U.S.—*Strychnine Sulphate* occurs in minute, prismatic crystals. It is soluble in water, and therefore preferable to the alkaloid for hypodermic use. Dose, one-twentieth of a grain.

BRUCINE.—Strychnine clings so closely to brucine that the physiological actions attributed to brucine have no doubt sometimes been caused by contaminating strychnine. There is good reason for suspecting that this happened in the elaborate investigation of L. Wintzenreid (*Dissert. Inaug.*, Geneva, 1882), who found that brucine acts as a stimulant to the spinal cord and a paralyzant to the motor nerves, but does not influence the cerebrum or the sensory nerves: in the higher animals, at first it increases the arterial pressure, and afterwards lessens it, paralyzes in large doses the vagi, causes death by asphyxia, and in other ways acts like strychnine. The more recent experiments of Lauder Brunton (*Journ. Chem. Soc.*, 1885) are in accord with the results obtained by Wintzenreid in showing that brucine causes spinal convulsions in mammals when injected directly into the circulation. Brunton found, however, that when taken by the mouth it produces no symptoms, probably because it is excreted as rapidly as it is absorbed. In an elaborate study, Professor Edward T. Reichert (*Med. News*, April, 1893) reached the conclusion that the physiological action of brucine is precisely that of strychnine, except that brucine is much less rapidly absorbed, is from forty to fifty times less powerful as a convulsant, is more poisonous to the sensory nerves, and more uncertain in its effect upon bodily temperature. Further, brucine appears to have an action upon the volitional centres of the frog different from that of strychnine, producing a brief period of motor paralysis preceding the stage of spinal convulsion (Mays, Reichert). Dr. Thomas I. Mays found that brucine locally applied to the nerves of the frog rapidly produces a paralysis of the sensory fibres (*Journal of Physiology*, viii). This led him to test it as a local anæsthetic in man, and he found that a five- or ten-per-cent. solution applied to the mucous membrane of the mouth caused rapid loss of sensibility. It is also asserted to exert a marked influence on the skin, a twenty-per-cent. solution applied to the back of the hand causing pronounced impairment of sensibility. Dr. Mays used this solution with excellent results for the relief of the itching of chronic *pruritus*. Dr. Ralph W. Seiss (*Therap. Gaz.*, vol. xviii. p. 459) and Dr. Charles H. Burnett have found that the application of a five-per-cent. solution in cases of inflammation in or about the external ear usually gives very marked relief. Dr. Burnett states that his results were far more satisfactory than those which he has obtained with cocaine. In using the brucine as a local anæsthetic it is essential that it be chemically pure: the *nitrate* or the *sulphate* may be selected, and one drop of hydrochloric or sulphuric acid should be added to the solution for each three grains of the alkaloid salt.

FAMILY VI.—DEPRESSO-MOTORS.

UNDER this heading are considered certain drugs which are used for the purpose of lessening the activity of the spinal cord. They have, except in this particular, but little in common in their action, and must be studied individually.

PHYSOSTIGMA—CALABAR BEAN. U.S.

An irregular, kidney-shaped bean, about an inch in length and three-fourths of an inch wide, the product of the *Physostigma venenosum*, a perennial woody creeper of Calabar, Africa, where the bean has been used by the natives as an ordeal test for criminals, witches, etc., since time immemorial. It contains an alkaloid known as *physostigmine*, or *eserine*. E. Harnack and L. Witkowski (*Arch. f. Exper. Path. u. Pharm.*, Bd. v.) have described a powerful tetanizing alkaloid, *calabarine*, which is sometimes abundant in commercial extracts of Calabar bean. As Professor Harnack has produced it from *physostigmine*, it is probably a decomposition product from that alkaloid (see also *Arch. f. Exper. Path. u. Pharm.*, viii. 125; ix. 434; x. 301). The probability that *physostigmine* readily undergoes decomposition is increased by the assertions of E. W. Ebers that there are seven organic principles in Calabar bean, —*eserine*, or *physostigmine*, *eseridine*, *calabarine*, *physostigmine-blue*, *rubreserine* (see Dietrich Schweder, *Dorpat Thesis*,* 1889).

PHYSIOLOGICAL ACTION.—When an animal receives a small fatal dose of Calabar bean, after a time muscular tremors appear, and almost immediately the animal falls to the ground, or lies down, in a state of perfect muscular flaccidity. The pupils generally contract,† and the respirations become slow, irregular, and often stertorous. All reflex actions are almost at once diminished, and this diminution grows greater and greater, until it ends in their complete abolition. So long as the condition of the motor system allows of it, evidences of sensibility are manifested whenever the animal is in any way injured. According to Clementi Papi (*Schmidt's Jahrb.*, Bd. cxlii. p. 287), the voice is completely lost. The muscular tremors persist during the whole period of paralysis, and, indeed, even after cessation of the respiration. They vary greatly in intensity, and in some cases are so severe (Frazer) as to simulate general convulsions. As the minutes go by, the rhythm of the respiration becomes more and more affected, and at last death

* For chemistry of Calabar bean, see this thesis.

† According to A. Dannemann (*Inaug. Diss.*, Kiel, 1891), in birds poisoned with *physostigmine* the pupil is contracted until just before death, when it dilates widely.

takes place quietly, consciousness being preserved until the last few gasping respirations close the scene. The pupils sometimes, but not always, dilate immediately after death. According to the experiments of Dr. Fraser, the bodily temperature is slightly elevated.

After a small lethal dose of the poison, the fatal result is always due to failure of the respiration, and if the body be at once opened the heart is found still beating; indeed, it has been seen to continue to do so for one and a half hours after death (Fraser). If a very large amount of the drug be given, the animal falls almost at once, paralyzed, with only a few muscular twitchings. The pupils contract, and in a very short time the gasping respiration ceases. The heart is now found distended and passive, but often will contract under the stimulation of a galvanic current.

Tremors have been seen after the administration of the so-called pure physostigmine by Rossbach and Fröhlich. Köhler, Rossbach, and others have even affirmed that Calabar bean produces a tetanic intoxication. A plausible explanation of these singular observations, and of many of the discrepancies of authorities, is to be found in the discovery of calabarine. Its discoverers state that it produces first a violent tetanus, and afterwards paralysis. It is plain how its presence in varying amounts in Calabar bean preparations would modify their action. The researches of Köhler, of Vintschgau, and of Rossbach and Fröhlich are especially open to doubt, on account of their statements that Calabar bean tetanizes. It is very probable that the extracts used by them contained a notable percentage of calabarine.

The symptoms induced by the drug in man are completely parallel with those that occur in the lower animals. They are giddiness, lessened heart-action, great muscular weakness, with, in most cases, contraction of the pupil, and sometimes with vomiting, and still more commonly with purging, which may be very free. A pupil of Gubler took 0.15 grain of the sulphate of eserine, and suffered, after a time, nausea, giddiness, and intense muscular weakness, so that he could not stand; three-quarters of an hour afterwards he vomited some of the solution mixed with bile, but his strength did not begin to return for two and a half hours.

The question here naturally arises, To what is the paralysis so prominent in poisoning by Calabar bean due? It is evident that the suspension of reflex action can have only three sources,—paralysis of the spinal cord, of the nerve-trunks, or of the muscles. I shall examine the action of the drug upon these organs in inverse order.

Muscles.—The continuance of the muscular movements after death indicates that they are due to a direct action of the drug upon the muscles. This conclusion is established by the experiments of Laschkewich (*Fürchow's Archiv*, 1866, Bd. xxxv. p. 294), of Fraser (*loc. cit.*), and of Leven and Laborde (*Schmidt's Jahrb.*, Bd. cxlvi. p. 136). All of these investigators have noted that after death these contractions are increased by

exposure to the air and by direct stimulation of the muscles; and Fraser has found that they occur in the frog during life after section of the supplying nerve, and also in a muscle actually cut out of the body. Laschkewich has confirmed the latter fact in the case of warm-blooded animals, and Leven and Laborde have proved that previous destruction of the lower end of the spinal cord in a guinea-pig does not prevent the development of the muscular twitchings in the hind legs. Schweder (*loc. cit.*) contends that the action of the poison is not, however, upon the muscular structure itself, but upon the peripheral nerve-endings in the muscle, basing his conclusions especially upon the alleged fact, that previous hypodermic injections of atropine or curare prevent the development of rigidity in the snake poisoned with physostigmine. It is certain that the final paralysis produced by Calabar bean is not of muscular origin, since at the time of death the contractility of the muscles is in no way diminished, but, on the contrary, Fraser has noted that loss of contractility and rigor mortis are greatly delayed in Calabar-bean poisoning.

Nerves.—The paralysis caused by the physostigma is not due to an action on the nerve-trunks, since Dr. Laschkewich, Dr. Vintschgau (*loc. cit.*, p. 161), and also Dr. Fraser, have found that when the galvanic current is applied to the crural nerve of either cold- or warm-blooded animals rapidly killed with Calabar bean, contractions are freely induced in the tributary muscles.

Indeed, the Scotch investigator, carrying his experiments still further, and using delicate instruments which it is not necessary here to describe, discovered that when the artery going to a hind leg was tied in a frog before the administration of the poison, after a quick death the rate of conduction of impulse was as rapid in the nerve to which the poison had had free access, as in its protected fellow. Notwithstanding these facts, the drug is not entirely without influence upon the nerves, since Dr. Fraser has found that when the blood-vessels of a frog's leg are tied, and the animal slowly poisoned by a small dose of the extract, while even many minutes after cessation of respiration both nerves seem equally intact, yet finally a time comes when the nerve of the poisoned leg refuses to react to the galvanic stimulus, although the functional power of the protected nerve, as well as of the muscles, is still perfect. This loss of functional power is probably rather in the termination of the nerve than in the trunk, for Dr. Fraser found that when all the blood-vessels supplying the gastrocnemius muscle were cut in a frog and the animal poisoned, at a certain time irritation of the crural nerve produced spasms of the gastrocnemius alone. It is to be noted that this perturbation of the peripheral nerves has only been seen in the frog when slowly poisoned, in which case the heart continues to beat long after the cessation of respiration, so that the nerves are as it were macerated in a solution of the poison. Its existence even in this feeble degree is denied by Harnack and

Witkowski. In frogs, and still more in warm-blooded animals, nerve-paralysis, if it exists at all, is of such slight intensity as to be of no practical importance.

The afferent nerve-fibres probably preserve their function after the motor fibres have been affected, as was seemingly proved in Dr. Fraser's experiments (*loc. cit.*, p. 19) by tying the vessels in the left leg of a frog which was afterwards poisoned with strychnine, when it was found that reflex movements were excited in the left leg by irritation of the right foot long after irritation of the left foot had ceased to cause movements in the right leg.

Dr. Fraser studied to some extent the effect of a strong solution of the poison when applied locally to a nerve, and found that the efferent fibres were affected before the afferent, and that finally the function of both of them was abolished.

Spinal Cord.—Since the abolition of reflex activity has its origin neither in the muscular system nor in the nerve-trunks, it must be spinal. The truth of this conclusion arrived at by exclusion has been abundantly demonstrated by direct experiment. Thus, Fraser, Harnack, Witkowski, and others have found that if in the frog a peripheral nerve be protected by tying its artery and the batrachian be poisoned with Calabar bean, the paralysis in the protected limb occurs *pari passu* with that in the remainder of the body. Again, Fraser divided the spinal cord of a frog, and then cut or tied all the blood-vessels going to the posterior section of it. After this, the animal was poisoned with physostigma, and, while the usual symptoms developed themselves in the anterior portion of the body, reflex actions were unaffected in the posterior part. Further, Dr. Fraser has found that when the poison is applied directly to the cord, fibrillary contractions,* due probably to a local irritant influence, are induced in the muscles supplied from below the point of application, but in a little while all movements cease, and even galvanization of the cord is itself unable to elicit response. It seems completely established by the evidence which has been brought forward that the most prominent effect of Calabar bean is a *depressant* action upon the spinal centres.

Recently, however, it has been asserted by Papi (*Schmidt's Jahrb.*,

* Several observers believe that Calabar bean, in small doses, acts as a stimulant to the spinal cord. Thus, M. Vintschgau (*Sitzungsab. Math. Nat. Classe Akad. Wissen. Wien.*, 1887, Bd. 17., Abth. II. p. 49) affirms that in a frog whose iliacs he had tied the poison produced violent convulsions, which affected the protected legs, and must, therefore, have been of central origin. Two plausible explanations of this suggest themselves: *First*, that the physostigmine used contained some active impurity; *second*, the well-known fact that certain spinal depressants produce convulsions, or even excited reflex action, by paralyzing reflex inhibition, or in some unknown way. The probability of impurity of alkaloid is increased by the assertion of Professor Harnack (*Arch. f. Exper. Path. u. Pharm.*, viii. 125; ix. 434; x. 301), that Merck's "calabarinum purum" contains little or no calabarine. Schweder, however (*Eeerin*, Dorpat Thesis, 1889), claims that the pure physostigmine, in small doses, acts as a distinct stimulant to the cerebral, respiratory, and vaso-motor centres.

Bd. cxlii. p. 287) that there is in frogs, preceding the stage of depression, one of exaltation of reflex action; and also, on the strength of some experiments upon animals with one-sided section of the optic thalamus, that the cause of loss of voluntary movement in Calabar bean poisoning is paralysis of the conducting fibres passing from the upper brain to the spinal centres. I have not been able to procure the original paper of Dr. Papi (*Gazz. Lomb.*, 1868), but his conclusions seem to me highly improbable. The primary stage of reflex activity probably was produced by calabarine present in the extract used by him.

Circulation.—Harley (*loc. cit.*, p. 151) and Papi (*loc. cit.*, p. 287) assert that Calabar bean has little or no influence upon the heart; but they are undoubtedly in error. According to Harnack and Witkowski, in the frog under the influence of the poison the heart's contractions become slower and stronger. When a mammal is poisoned with small doses, the cardiac action of the drug is subordinate to that upon the nerve-centres; but, as has been shown by Dr. Fraser, when very large doses of the poison are administered, especially if they be injected into the jugular vein, death results from syncope or from consentaneous failure of the cardiac and the respiratory functions, and the heart is found arrested in diastole, flaccid, but, according to Dr. Fraser and to Drs. C. Arnstein and P. Suetschinsky (*Untersuch. Physiolog. Laborator. Würzburg*, Theil ii. p. 86), responding, though feebly and uncertainly, to direct stimulation. In the frog, Roszbach and Fröhlich (*Pharmak. Untersuch.*, i. p. 56) have found that the arrested heart is insensible to stimuli.

When smaller doses of the poison are exhibited, there is slowing of the heart's action, as has been noted by Laschkowich (*loc. cit.*, p. 298), by Fraser (*loc. cit.*, p. 48), by Dr. J. Tachau (*Archiv der Heilkunde*, 1865, p. 70), and by other observers. Although, according to the experiments of Dr. Fraser, there is at first a slight fall of the blood-pressure, which is probably due, as he believes, to diminished pulso-frequency, yet, in spite of the continuance of the slow pulse, the arterial tension soon recovers itself, and remains for a long time much above the normal point, while at the same time the individual cardiac beats are greatly increased in strength (Fraser, Bezold and Gotz*). Finally, the arterial pressure falls far below normal, and the power of the heart is gradually extinguished.

The question as to the exact method in which these changes are wrought is of very difficult answer. The long diastolic pauses and the slow strong beat of the heart suggest at once that a chief action of the drug is upon the inhibitory cardiac nervous system. Tachau, however (*loc. cit.*, p. 172), found that after section of the vagi the poison

* I have not seen the original paper of these authorities in the *Centralblatt für Med. Wissenschaft*, 1867, but quote them from the paper of Arnstein and Suetschinsky.

produces these phenomena in an even more intense degree than in the normal heart. As this has been confirmed by Lasechewich (*loc. cit.*), by Fraser (*loc. cit.*, p. 49), and by Harnack and Witkowski (*loc. cit.*, p. 419), it must be accepted as a proved fact, especially since Vintschgau has found (*loc. cit.*, p. 71) that if in the frog the brain and the medulla be destroyed, physostigmine still acts in its usual way on the heart.* Tachau considers that this demonstrates that the cardiac phenomena of Calabar bean poisoning are not due to an action of the drug upon the inhibitory nerves. Arnstein and Sustschinsky, however, admitting the fact, deny that it warrants the conclusion. Their idea appears to be that it is conceivable that a substance should so act upon the peripheral inhibitory nerve-endings as to cause them to influence the action of the heart without any external impulse, and consequently when separated from the nerve-centres. Köhler, Harnack, and Witkowski have all found that in the frog Calabar bean still lessens the pulse-rate after complete paralysis of the peripheral vagi by atropine† (*Archiv f. Exper. Path. Pharm.*, Bd. i. p. 280). Köhler believes that his experiments prove that the Calabar bean paralyzes the cardiac accelerator nerves. It will be remembered, however, that Vintschgau found that Calabar bean exerts its normal influence upon the heart after destruction of the accelerator centres. Whatever may be the action of small doses of physostigmine upon the vagi and accelerators, it seems to me that it must be considered established that the general cardiac symptoms are due to a direct action upon the heart-muscle or its contained ganglia.

In regard to the action of the drug upon the peripheral vagi, the following *résumé* of the evidence is of interest. Arnstein and Sustschinsky found that the excitability of the peripheral cardiac vagi is increased by Calabar bean. They first tested the effect of graduated galvanic currents applied to the divided vagi in the animal to be experimented with, until the exact strength of the weakest current capable of causing diastolic arrest was demonstrated, and then exhibited the drug and tested the nerves afterwards. They used in these experiments both rabbits and guinea-pigs, and found that, without a single exception, currents much weaker than those which previously were barely effective would, after the poisoning, stop the heart; also the super-excitability of the peripheral inhibitory nerves was shown by the fact that under the influence of the drug the diastolic arrest continued much longer than normal after the withdrawal of the stim-

* The fact that Calabar bean acts in its usual manner after section of the par vagum indicates that it has no influence upon the inhibitory centres,—a conclusion confirmed by Arnstein and Sustschinsky (*loc. cit.*, p. 102), who found that an injection of the drug into a carotid—i.e., into the inhibitory centre—did not cause any marked immediate diminution in the number of the cardiac pulsations.

† Rosebach and Fröhlich (*loc. cit.*, p. 58) assert that in frogs, although the vagi are not more excitable before than after the poisoning, stimulation of the venous sinuses and of the auricles has much more than the normal influence,—which is very extraordinary, if true.

ulus from the vagi. These experiments have been directly corroborated by Rossbach and Fröhlich upon the rabbit (*loc. cit.*, p. 57). Dr. Fraser's experiments upon the local cardiac application of the drug are also seemingly confirmative of those of Arnstein and Sustschinsky, for he found that when the poison was put directly on the heart, or into one of its chambers, it caused a prolonged diastolic pause, followed by contractions interrupted by pauses, and finally by resumption of regular contractions, or else by diastolic arrest, the heart still retaining its power of responding, in an embarrassed manner, to stimuli. These experiments certainly seem to prove that Calabar bean does cause excitation of the peripheral cardiac apparatus. Arnstein and Sustschinsky further confirm them by other experiments of much interest. They injected into rabbits such amounts of atropine as completely to paralyze the peripheral cardiac vagi, so that the strongest currents when applied to the nerves failed to influence the heart's action, and then *restored functional power* to the pneumogastrics by injections of Calabar bean, so that currents of moderate intensity caused diastolic arrest. These experiments, if accurate, prove that physostigmine is a powerful excitant of the peripheral vagi. Köhler (*loc. cit.*), using the frog, and Rossbach and Fröhlich, using the rabbit, failed to resuscitate the atropinized vagi by means of Calabar bean, but it is evident that a negative result in such a case might be due to an improper proportion in the doses of the counter-poison, or to the atropine being employed in overwhelming amount. In warm-blooded animals, at least, the vagi are not paralyzed during life by physostigmine, as is evinced by the experiments of Arnstein and Sustschinsky (*loc. cit.*, p. 101), confirmed by Harnack and Witkowski (*loc. cit.*, p. 433). Some of the results obtained by Fraser (*loc. cit.*, p. 36), confirmed by Rossbach and Fröhlich, apparently contradict but in reality accord with them. In the frog there was, indeed, at last a loss of functional power in the vagi, but not until very long after the cessation of respiration, after all the nerves of voluntary motion had lost their functional power,—i.e., after death would have occurred in a mammal. Harnack and Witkowski affirm that the vagi never lose their power in the frog to lessen the rate of the heart-beat, although unable to cause diastolic arrest.

In summing up the evidence in regard to the action of the drug upon the vagi it is plain that no positive conclusion can be reached, although it seems probable that the drug *first increases and then lessens the power of the inhibitory nerves over the heart.*

As already stated, a very prominent phenomenon in Calabar bean poisoning is rise of the arterial pressure. This, of course, may be of cardiac origin, or it may be due simply to a contraction of the arterioles, or it may arise from a combination of these causes. Bezold and Götz (quoted by Arnstein and Sustschinsky, p. 87) found that the arterial pressure still rose under the influence of the drug after section of the spinal cord high up,—i.e., after general vaso-motor paralysis.

Harnack and Witkowski also found that when the vaso-motor centres were paralyzed with chloral, physostigmine caused very decided increase of the arterial pressure. It is evident that the increased force of the circulation produced by physostigmine must, at least in part, be due to a direct action of the drug on the heart.

The fact that the rise of arterial pressure produced by Calabar bean is not so great in animals whose cords have been divided as in those uninjured certainly indicates, though it does not prove, that the increased arterial tension of physostigmine-poisoning is in part due to *vaso-motor spasm*. Dr. Fraser believes that Calabar bean does produce this spasm; but his evidence is insufficient to establish his conclusion. It consists simply of some experiments upon frogs in which the spinal cord was divided, and, the animal being put on a "frog-plate," the arteries of the web were watched while Calabar bean was exhibited. Dr. Fraser believed that under these circumstances the arteries contracted considerably at first, and afterwards dilated. Dr. Harley (*Practitioner*, 1869, iii. 163) states as the result of his studies that Calabar bean can be seen, when applied locally, to cause contraction of the veins, the arteries remaining unaffected; while Dr. Fraser, in contradiction to this, believes that he has demonstrated that the local application of physostigma produces dilatation of the arteries. It is not necessary here to reiterate my objections to such evidence as this. If, under the circumstances of the first-mentioned experiments of Dr. Fraser, Calabar bean contracts the small vessels, it must be by a peripheral, not centric, action, since the vessels were separated by the division of the cord from the vaso-motor centres. It is plain that this is in direct contradiction to Dr. Fraser's experiments on the local application of the drug. Again, it is contradictory, rather than confirmatory, of that furnished by the study of the blood-pressure. The only logical conclusion seems to me to be that at present we have not proof that Calabar bean acts upon the vaso-motor nervous system. As the increase of the arterial pressure is in great part, if not altogether, due to the increased energy put forth by the heart under the influence of physostigmine, and as that influence is exerted directly upon the heart-muscle or its ganglia, it is evident that physostigmine directly causes the heart to put forth more effort, or, in other words, stimulates it. The final diastolic arrest (the loss of the power of responding to stimuli) shows, however, that at last the poison paralyzes the heart. In considering the general physiological action of the drug, it must not be forgotten that its influence upon the heart is entirely subservient to its influence on the nervous system,* and that death in the mammal occurs before the stage of cardiac palsy is reached, unless the drug be injected directly into the heart in overwhelming dose

* For a discussion of the peculiar cardiac relations of physostigmine and muscarine, see the paper by Harnack and Witkowski. Those authors believe that Calabar bean sets in motion the heart arrested in diastole, not by paralyzing the cardiac inhibitory apparatus, but by stimulating the cardiac muscle.

I do not believe that physostigma has much action upon the blood. Certainly its influence upon the nervous system is a direct one, since Lewiasson (*Reichert's Archiv*, 1870) has found that it acts upon the "salt frog" as upon the normal animal. The alterations noted by Dr. Fraser in the blood are probably produced by the asphyxia which precedes death: these alterations are that the blood coagulates slowly and loosely, and the red disks in dogs and in rabbits present various irregularities of outline, among which may be noted a well-marked stellar crenation, but that the respiratory function of the blood is not interfered with.

Intestines.—Intestinal peristalsis is very much increased by the action of Calabar bean (Westermann, *Schmidt's Jahrbücher*, Bd. cxxxviii. p. 290; Papi, *Ibid.*, Bd. cxlii. p. 287; Fraser, *loc. cit.*, p. 57). After poisonous doses there is at first a stage of exceedingly active movements in the bowels; then spasmodic tetanic contraction of the intestines occurs, so that their calibre is very much diminished; and finally relaxation and dilatation take place. After death the vermicular movements are found very much lessened (Fraser), or altogether abolished (Tachau, *loc. cit.*, p. 73).

The action of Calabar bean upon the intestines appears to be peripheral, due to contact of the poison in the blood with the muscular fibres or the ganglionic nerve-cells in the walls of the bowels. For Westermann (*loc. cit.*, p. 291) found that extirpation of the cardiac ganglion had no effect upon the action of the drug, but that tying of the mesenteric and of the coeliac arteries, before poisoning, prevented any increase in the peristalsis. Calabar bean probably influences intestinal secretion. Its action upon the salivary glands is often decided, and according to Heidenhain is not prevented by atropine.

Eye.—Calabar bean, as is well known, strongly contracts the pupil, both when applied to the eye and when exhibited internally. Evidently, as in the case of atropine, the pupillary action of Calabar bean should be studied from two points of view, the local and the constitutional.

The closeness of the analogy between the pupillary action of atropine and that of Calabar bean is seen in the fact that, like the former, the latter, as shown by the experiments of Vée and Leven on chickens (*Comptes-Rendus Soc. Biolog.*, 1865, p. 161), does not affect the irides of birds. Thus, analogy would seem to prove that the influence of Calabar bean is directly upon the peripheral nerves of the iris.

Although, then, I am not able to cite any direct experimental proof, yet it seems to me scarcely doubtful that the contraction of the pupil produced by Calabar bean is always a local, peripheral influence, whether the drug be placed in the eye from the outside or be carried through the general circulation. It is evident that the myosis may be caused in one of three methods,—by paralysis of the sympathetic fibres, by stimulation of the oculo-motor fibres, or by a conjoint action upon both sets of nerve-endings. In which of these ways the drug acts, we are not yet able to decide.

It has been held by various authorities that if galvanization of the sympathetic fibres in the neck fail to expand a contracted pupil, the myosis must be due to paralysis of the sympathetic. Evidently, however, this is claiming too much, for, as pointed out by Grünhagen (*Virchow's Archiv*, Bd. xxx. p. 521), it is conceivable that an oculo-motor spasm can exist of such intensity that the antagonistic nerve is unable to dilate the pupil. The question arises very pertinently at this point, What is the fact in regard to Calabar-myosis? Does or does not galvanic stimulation of the cervical sympathetic dilate the pupil? The testimony is somewhat conflicting. Dr. Grünhagen (*loc. cit.*, p. 521) says that dilatation always occurs, although to a slight extent (*in beschränkten Masse*); while, on the other hand, Dr. Gustav Engelhardt (*Untersuch. a. d. Physiolog. Laborator. in Würzburg*, Theil ii. p. 526) has found that galvanization of the cervical sympathetic has no effect upon the contracted pupil. The experiments of Fraser (*loc. cit.*, p. 60), of Bernstein and Dogiel, and of Rosenthal (*Reichert's Archiv*, 1863), would seem to reconcile these differences, and, by their accord, to prove that under the maximum influence of Calabar bean the sympathetic is powerless, while when the contraction is the result of a milder influence of the drug, stimulation of the cervical nerve will cause a certain amount of dilatation.* Fraser, and also Engelhardt, have found that if the poles of a battery be applied directly to an iris even most profoundly contracted by physostigma, immediate dilatation occurs. These facts, for reasons stated above, do not absolutely prove, but they certainly render it highly probable, that Calabar bean *paralyzes the peripheral sympathetic nerve fibres* in the iris. It is, however, almost equally probable that there is a *consentaneous stimulation of the oculo-motor terminations*; for the myosis caused, like the mydriasis produced by atropine, is an active, not a passive, condition, and is not only much more forcible, but is also much more complete, than that which follows section of the cervical sympathetics. The observations of Rossbach and Fröhlich, that overwhelming doses of physostigmine finally dilate the pupil, have been confirmed in cases of human poisoning (see Leibholz, *loc. cit.*). It would seem, therefore, that when the alkaloid is in sufficient amount the primary oculo-motor stimulation is followed by oculo-motor palsy.

Urine and Elimination.—The alkaloids of Calabar bean have been found in various secretions by Dragendorff and his pupil, Pander, but it chiefly escapes with the urine. Its absorption and elimination are very rapid, as both N. Teich and D. Schweder have found it in the urine a half-hour after ingestion. No studies of its influence upon urea

* Recently Rossbach and Fröhlich affirmed that galvanization of the sympathetic still causes dilatation, even when the action of the physostigmine is most vigorous. As it is scarcely conceivable that the various other investigators should have been so much in error, it is probable that Rossbach and Fröhlich used such strong currents that they were directly transmitted to the iris.

elimination in health are known to me, but according to Dr. Merson (*Journ. Ment. Sci.*, Jan. 1875) it decreases the urea and other urinary solids in paresis.

Summary.—The dominant physiological action of Calabar bean is a persistent depression of the motor centres of the spinal cord, involving also the respiratory centres in the medulla, and producing loss of reflex action with an increasing paralysis, ending in death from paralytic asphyxia. Contraction of the pupil is usually seen in the poisoning, and is always produced by the local application of the drug; it is due to a peripheral influence and probably to stimulation of the oculo-motor nerve-endings. The motor nerve-trunks are scarcely affected, but in slow poisoning probably suffer some depression of function. Neither the cerebral cortex nor the sensory nerve nor the sensory nerve-centres are acted upon, unless possibly in the latest stages of poisoning. Calabar bean acts directly either upon the muscle structure itself or upon the peripheral nerve-endings in the muscles, producing contraction and not paralysis. The influence of the drug upon the circulation is entirely subordinate, and is not at present completely understood. Early in the poisoning there is a rise of the blood-pressure, which is in great part, if not altogether, due to a direct stimulation of the cardiac muscle or its contained ganglia. The action of the drug upon the vaso-motor centres remains at present in doubt. Intestinal peristalsis is greatly increased by a direct action of the Calabar bean upon the muscular fibres or the peripheral nerve-endings in the intestinal walls. The alkaloids of Calabar bean are rapidly absorbed, and are eliminated chiefly by the kidneys.

THERAPEUTICS.—The physiological action of Calabar bean has suggested its use in spasmodic affections, in atony of the muscular coats of the bowel, and in various diseases of the eye.

The action of Calabar bean upon the spinal cord very early led to its use in spasmodic affections, and especially in *tetanus*, in which disease it has been more freely employed during the last few years than any other remedy except opium. In the paper of Dr. B. Roemer (*St. Louis Med. Surg. Journ.*, 1873, p. 367) are collected forty-seven cases, of which twenty proved fatal. To these I am able to add the twenty whose references are given below,* making in all sixty-seven cases, with thirty-seven recoveries and thirty deaths,—not a very flattering record.

* **FATAL CASES.**—Fenwick, 1 (*Glasgow Medical Journal*, 1869, p. 300); Franzolin, 1 (*The Doctor*, Oct. 1, 1871); Laborde, 1 (*British Medical Journal*, June, 1872); Valdivieso, 1 (*Philadelphia Medical Times*, vol. i. p. 455; Tyson, 1 (*Ibid.*, p. 418); Johnson, 1 (*Ibid.*, p. 372); 1 (*London Lancet*, 1874); Silbermann, 1 (*Charrier's Thesis*, 1881); Delamarre, 1 (*Paris Thesis*, 1875); Richelot, 1 (*Thèse de Concours*, 1875). **RECOVERIES.**—Fenwick, 1 (*Glasgow Medical Journal*, 1869, p. 300); Newman, 1 (*Medical Examiner*, July, 1869); W. W. Keen, 1 (*Philadelphia Medical Times*, vol. i. p. 195); J. H. Packard, 1 (*Ibid.*, p. 138); Cunningham, 1 (*British Medical Journal*, i. 1874); 1 (*Cincinnati Lancet*, Sept. 1878). All these cases were of the traumatic form of the disease. Charrier, 1 (*Paris Thesis*, 1881); Burnam, 1 (*Lancet*, Jan. 1881); Pooley, 1 (*New York Med. Journ.*, Sept. 1878); Silbermann, 1 (*Charrier's Thesis*, 1881).

It is, however, proper to state, as affecting the value of these statistics, that much of the Calabar bean extract which has been offered in the market is practically inert, and in all probability in some of these cases the drug did not have a fair trial; and that when especial care was taken by certain observers better results were achieved, although on so small a scale as to leave the issue in much doubt.*

In *trismus neonatorum*, Calabar bean has been employed with results certainly no more encouraging than those obtained in tetanus. In *chorea* it has also been used by some practitioners with asserted advantage, but further experience hardly justifies its administration (see *Bull. Gén. Thérap.*, lxxxix. 83, 541).

The physiological action of physostigma upon the unstripped intestinal muscle-fibres has led to its employment in *atony* of the muscular coat of the bowels and other similar organs. Dr. V. Subbotin (*Archiv f. Klin. Med.*, Bd. v. p. 285, 1869) has used the extract with the happiest results in a case of *chronic bronchial catarrh* with intense *dyspnœa*, believed to be due to weakness of the bronchial muscular fibres, and also in one of apparently "*phantom tumor*," with *chronic intestinal dyspepsia* and *catarrh*. In *constipation* dependent upon relaxation it is also said to be useful. Dr. A. Miller strongly endorses the value of the extract in *chronic intestinal atony*, after or during a *catarrh*, in the convalescence from fever, etc., and in *constipation* with flatulence, in meteorism, etc. (*Charité-Annalen*, 1883, 235).

Calabar bean has also been employed in *strychnine-poisoning*, and a recovery obtained after the ingestion of three grains of the latter alkaloid is reported by Dr. J. W. Keyworth (*Glasgow Med. Journ.*, N. S., 1869, i. 54).†

In *epilepsy*, some trials have been made of the drug, but its value is very doubtful. Drs. Harnack and Witkowski have found that in epileptic guinea-pigs physostigmine causes a succession of fits lasting for hours and days. They have further noted a similar influence upon man. Attention has also been called to the employment of Calabar bean as a *galactagogue*, the extract being applied to the breast itself (*Brit. Med. Journ.*, 1876, ii. 554).

ADMINISTRATION.—Calabar bean is usually administered as an *extract* (*Extractum Physostigmatis*, U.S.), the commencing dose of which is one-tenth to one-fifth of a grain. The dose of the *tincture* (*Tinctura Physostigmatis*—15 per cent., U.S.) is twenty to forty minims. The alkaloid is preferable, on account of its certainty. The U.S. Pharmacopœia recognizes both the sulphate (*Physostigminæ Sulphas*, U.S.) and the *salicylate* (*Physostigminæ Salicylas*, U.S.). The latter of these salts is preferable as more permanent, the sulphate being very deliquescent. The dose

* For a favorable record, see Watson, *Glasgow Medical Journal*, N.S., 1869, vol. i. p. 34; consult also *London Practitioner*, Sept. 1869.

† The subject of the asserted antagonism between chloral and Calabar bean will be studied in the article on chloral.

of the two is the same. Bouchut found that in children one-twentieth of a grain of a salt of physostigma, given hypodermically, will produce very decided symptoms, which entirely pass off in about three hours. It is probable that one-fifteenth of a grain, repeated every three hours, will be found to be a not too large dose for the adult. It should always be borne in mind that in tetanus and other severe diseases it is necessary to augment the dose until an effect is produced. Harnao gives the minimum fatal dose of eserine as for dogs four to five, rabbits three, cats two to three milligrammes. The frog resists these doses successfully.

Toxicology.—So far as I know, Calabar bean has not been used, either in Europe or in this country, with criminal intent. In Liverpool seventy children were accidentally poisoned at one time (*Med. Times and Gaz.*, Oct. 1864, p. 406). Many of the victims vomited spontaneously, and thus relieved themselves. Those brought to the hospital were in a state of extreme prostration and muscular relaxation. They appeared to suffer almost no pain, only some of them saying they had a little "belly-ache." Among some thirteen examined, only one had the pupils contracted. The only child who did not recover was excessively weak, and, crying out suddenly, was dead of sudden syncope. The heart was found relaxed and flabby, both sides equally full of blood. Half a bean produced in a strong man (*St. Barthol. Hosp. Rep.*, 1879, xv.) great muscular weakness, tightness across the chest, temperature of 96.6° F., very slow, intermittent, irregular pulse, and collapse, without vomiting, purging, contraction of the pupils, or abdominal pain. Dr. Lodderstaedt (*Berl. Klin. Wochenschr.*, 1888) reports a hypodermic injection of one-half a milligramme of the sulphate of eserine in a boy nine years old, followed in a quarter of an hour by violent headache, free sweating, salivation, slowing of the pulse, repeated vomiting, contraction of the pupils, and, finally, deep collapse, from which, however, the patient recovered. Two girls took between them 0.1 gramme (153 grains) of physostigmine, with the result of sudden unconsciousness, great redness of the face, muscular relaxation, vomiting, widely dilated, immovable pupils, and, on recovery of consciousness, violent abdominal pains, with pulse 60, and hard; recovery after some hours (*Leibholz. Vierteljahrsch. f. Gerichtl. Med.*, Berlin, 1892).

In 1864 Dr. Kleinwachter treated a case of poisoning by an unknown quantity of atropine with Calabar bean, apparently with great benefit. Dr. Bourneville detailed in 1867 some experiments which seemed to show that there is a real antagonism between Calabar bean and the mydriatic, and in 1870 (*Revue Photograph. des Hôpitaux*) published five experiments upon guinea-pigs, which were very decisive in that a proved fatal dose of physostigma was given in each case and recovery obtained by the use of non-lethal doses of atropin. In 1869 Professor Roberts Bartholow, of Cincinnati, on the strength of a few really indecisive experiments, arrived at a conclusion opposite to that of Bourneville. Recently, Dr. Fraser, of Edinburgh, has investigated the subject

in so thorough a manner that his essay may serve as a model for those who are desirous of studying questions of antagonisms between poisons. His experiments, three hundred and thirty-one in number, were made chiefly upon rabbits, a few having been upon dogs. He first investigated as to the minimum fatal dose, per pound of the animal, of the preparations used,—the extract of the bean, and the sulphate of eserine. It was ascertained that the minimum lethal dose for rabbits of the extract of physostigma which he employed was 0.4 grain per pound; of the sulphate of eserine, 0.04 grain per pound. Then in sixteen experiments in which recovery followed the administration of a dose of atropine given in combination with a dose of physostigma equal to or in excess of the minimum fatal dose, the animal used was killed long afterwards by a dose of the Calabar bean less than or equal to that from which recovery had occurred under the influence of atropine. In this way a perfect demonstration of the power of the counter-poison was obtained.

It was found that the counter-poison acted most efficiently when thrown directly into the veins. Thus, a rabbit weighing three pounds and two ounces received 1.6 grains of the extract, and five minutes afterwards 0.02 grain of atropine, in a vein, and recovery took place; eight days after this, 1.3 grains of the extract killed the same rabbit in nineteen minutes: in another animal which nine days before had been saved from death after the exhibition of 2 grains of the extract by 0.5 grain of the sulphate of atropine, 1 grain of the extract proved fatal in thirteen minutes.

The next series of experiments was undertaken to ascertain the maximum dose of physostigma that can be successfully antagonized by atropine, and the dose in which the latter should be employed. In all cases the atropine was given five minutes before the Calabar bean. It was found that one-fiftieth of a grain of the mydriatic would successfully antagonize one and a half times, but not twice, the minimum fatal dose of the myotic.

One-fortieth of a grain of the atropine was successful against two to two and a half times the minimum lethal dose of physostigma; three fiftieths was sufficient for three times the minimum fatal dose. The small size of the required doses of atropine is very noticeable, and at the present point in the investigation a very curious result was obtained. It was found that when three times the minimum fatal dose of the Calabar bean were exhibited, the successful dose of atropine ranged from three-fiftieths of a grain to one grain and a fifth. When three and a half times the fatal dose of the physostigma were exhibited, success was achieved only with doses of atropine of from one-tenth to one-fifth of a grain. Unfortunately, there are only seven experiments bearing upon this point; yet its general accuracy, I think, can scarcely be questioned. When a rabbit received four times the lethal dose of physostigma, the mydriatic was powerless.

In the final series of experiments, the atropine was administered five minutes after the physostigma, and it was found that the largest dose of the latter which could be combated successfully was three times the minimum fatal dose, and the range of the dose of atropine was much less than when it was given before the poisoning. Thus, with three times the minimum lethal dose of the Calabar bean, death occurred when three-twentieths or one-fifth of a grain of the antidote was given, but recovery followed the administration of four-twenty-fifths of a grain.

No experiments were made to test the value of physostigmine in atropine-poisoning. Dr. Fraser states, however, on what grounds I do not know, that the minimum fatal dose of atropine in rabbits is twenty-one grains; and he found that when one-half the minimum lethal dose of physostigmine is given, together with nine and four-fifths grains, or more, of atropine, death results.

These experiments of Fraser have been in some degree confirmed by the imperfect researches of Amagat (*Journ. de Thérap.*, 1876). Considerations previously given, however, show that the cardiac antagonism of atropine and physostigmine must be considered doubtful, and, if it exists, is of little importance. Whatever of life-saving power the mydriatic has in Calabar bean poisoning is evidently dependent upon its stimulant action on the respiratory centres.

The question naturally arises, How far are the results of these experiments applicable to the treatment of Calabar bean poisoning in man? Without discussing this at length, I think the following deductions are obvious: first, that atropine ought by all means to be tried in poisoning by physostigma; second, that the doses of it should never be very large, not exceeding in all the tenth of a grain. The use of atropine should, of course, not cause neglect of such measures of relief as evacuation of the stomach, the external application of dry heat, etc., usual in poisoning by sedative narcotics. Artificial respiration should, when necessary, be assiduously practised, since death undoubtedly is due to failure of the breathing, and Harnack and Witkowski have found that animals survive very large doses of the poison when respiration is maintained artificially.

POTASSII BROMIDUM—POTASSIUM BROMIDE. U.S.

The bromide of potassium is prepared, according to the official method, by precipitating freshly-made solution of bromide of iron by the pure carbonate of potassium, filtering, and evaporating the resultant solution. It occurs in milk-white cubic or quadrangular prismatic crystals of an acrid saline taste, freely soluble in water and slightly so in alcohol. When its solution is mixed with starch, and chlorine is added, a yellow color is developed. A bluish tint betrays contamination with an iodide.

PHYSIOLOGICAL ACTION.—Local Action.—When a solution of the bromide is applied locally to the heart, it produces instantly marked lessening of its action, and, if in sufficient amount and concentration, even instantaneous diastolic arrest (*Virchow's Archiv*, xli. 101). Upon the voluntary muscles it acts in a similar manner when similarly applied. If its solution be not too concentrated or abundant, however, the muscle of the frog is first thrown into a tetanic spasm (*Dublin Journ.*, xlvii. 325); and Dr. Purser suggests that the tetanic symptoms seen in the frog poisoned by the bromide of potassium are due to this action on the muscles. On the nerve-trunks, and also on the nerve-centres, the bromide acts, when applied locally, as a paralyzing poison (*Bull. Thérap.*, lxxiii. 253, 290; also Dr. Amory, *Physiolog. and Therap. Action of the Bromide of Potassium*, Boston, 1872, Part II., p. 147; also Ringer and Morshoad, *Journ. Anat.*, xii. 71). It is, therefore, evident that the bromide of potassium in sufficient quantity is a deadly poison to all the higher animal tissues. In general poisoning of animals by hypodermic injection of the bromide, this local action is often very manifest, and paralysis of the part into which the solution has been thrown follows very rapidly upon the injection. In the form of powder it is affirmed to be somewhat caustic, and has been highly recommended for the destruction of excessive granulations, etc. (*Brit. Med. Journ.*, 1876, ii. 496).

General Action.—Bromide of potassium administered to frogs in minute doses produces as a first result a tetanoid condition, in which there may be very marked opisthotonos. After a short time this stage of muscular excitement gives way to one of great muscular relaxation and total abolition of reflex actions. Voluntary movements, however, often occur during this period, and the frog which has been lying limp and apparently dead will startle the observer by a sudden vigorous leap. This fact has been so frequently witnessed that there can be no doubt of its truth. It is vouched for by the following observers: J. M. Purser (*Dublin Journ. Med. Sci.*, xlvii. 324, 1869); Lewinsky aus Kazan (*Virchow's Archiv*, Bd. xlv. p. 191, 1869); J. V. Laborde (*Archives de Physiol. Norm. et Pathol.*, t. i. p. 423, 1868, and *Comptes-Rendus*, t. lxx., 1867); MM. Damourette and Pelvette (*Bull. Thérap.*, 1867, lxxiii. 249). Very early in the paralytic stage the respiratory movements are affected, and they gradually grow less until their final arrest. When a very large dose of the bromide is given, death may be induced by paralysis of the heart (Albert Eulenberg and Paul Guttman, *Virchow's Archiv*, xli., 1867); but after a small toxic dose this viscous continues to beat long after the cessation of breathing. If the drug be given by an injection practised in the vicinity of the heart, sudden cardiac arrest always occurs.

Upon mammals (*Bull. Thérap.*, lxxiii. 256; *Virchow's Archiv*, xh. 97) the bromide acts very much as upon frogs, inducing progressive paralysis, depression of temperature, and death by asphyxia when given

in small poisonous doses, and great disturbance of the circulation, with finally diastolic arrest of the heart, when very freely administered.

So far as I know, no fatal case of acute poisoning by the bromide of potassium is on record. In my own experience an ounce taken by mistake by a young adult produced violent pain in the œsophagus, nausea with a little vomiting, great thirst, feeling of weight in the head, and excessive sleepiness, which lasted for three days. In a case reported by Dr. Dougall (*Glasgow Med. Journ.*, Feb. 1893) an ounce and a half taken within twenty-four hours was followed by coma, with weak pulse, cold extremities, temperature 96.8, total abolition of the reflex action, and general cutaneous anaesthesia, followed by excessive drowsiness interrupted by periods of talking delirium and by periods of rationality; the symptoms gradually subsiding in a fortnight.

The results of the continuous employment of large doses of the bromide, however, demonstrate that it acts upon man as upon the lower animals. When it is taken with sufficient freedom to accumulate in the system, a conjunction of phenomena known as *bromism* arises. The cerebral symptoms are a sense of mental weakness, heaviness of intellect, failure of memory, partial aphasia, great somnolence, and depression of spirits. With these there may be decided impairment of the sensibility of the mucous membranes and of the skin, so that titillation of the fauces may be without effect, and, according to Puche, even heat applied to the skin calls forth no complaint: Huetto (*Mémoires de la Soc. Biolog.*, 1850) has seen in some cases absolute anaesthesia of the sclerotic conjunctiva. The sexual function is abolished. There is also very generally fetid breath, and an eruption of acne, which may indeed be very severe. Of course, in any individual case of bromism many of these symptoms may be wanting; but when the use of the remedy is persisted in, they all at last become developed in an intense degree. Professor Edward H. Clarke thus speaks of a case which came under his notice: "The fetid breath becomes nauseous; œdema supervenes on congestion of the uvula and fauces; the whispering voice sinks into aphonia; sexual weakness degenerates into impotence; muscular weakness becomes complete paralysis; reflex, general, and special sensations disappear; the ears do not hear, nor the eyes see, nor the tongue taste; the expression of hebetude becomes first that of imbecility, then that of idiocy; hallucinations of sight and sound, with or without mania, precede general cerebral indifference, apathy, and paralysis; the respiration, without the stertor of opium or alcohol, is easy and slow; the temperature of the body is lowered; as the bromism becomes more profound, the patient lies quiet in bed, unable to move or feel or swallow or speak, with dilated and uncontractile pupils, and scarcely any change of the color of his skin or face." Death has been attributed to the effect of the continuous use of the bromide in large doses. Thus, Dr. Hameau reports (in the *Journ. de Méd. de Bordeaux*) the case of a young woman who took four and a half pounds during the course of

ten months, and while in a condition of cachexia, with yellowish skin, a copper-colored eruption upon the forehead, colic, gastralgia, insomnia, etc., suddenly became greatly prostrated, and had delirium with profuse sweats, followed by death in four days. Dr. Anton Eigner (*Wiener Med. Presse*, Nos. 25 to 34, 1886) details the case of a woman who took five pounds in less than a year, and while having very pronounced symptoms of bromism was seized with delirium and suffered from hallucinations of sight and hearing, saying she was being poisoned, and finally died of pneumonia. In neither of these cases can it be considered probable that the bromide was the direct cause of death.

Action on Nervous System.—The persistence of voluntary movement in the frog after the abolition of reflex actions shows that the influence of the drug is not chiefly exerted upon the cerebral centres of motor impulse, nor upon those cells of the cord which originate movement, but upon either the afferent nerves or those portions of the cord which transmit the impulse from these nerves to the cells presiding immediately over motion. This is confirmed by some experiments of Lewisky, in which it was found that previous separation of the cord from the cerebrum had no influence upon the action of the bromide. Both he and Purser also found that death occurred from small doses before the motor-nerve trunks and the muscles had lost their irritability (confirmed by Saisson, *Schmidt's Jahrb.*, Bd. cxliii. p. 17). This being so, the question arises whether the paralysis be spinal or due to paralysis of the peripheral afferent nerves. There is an apparent conflict in the evidence upon this point. Eulenberg and Guttmann (*loc. cit.*, p. 103) found that when access of the poison was prevented to one or more limbs by tying the arteries, reflex actions were abolished in these parts as rapidly as in others. Similar results have been obtained by Lewisky, by Roberts Bartholow (*Bromides*, Providence, 1871), by Purser* (*loc. cit.*, p. 326), and by Laborde (*loc. cit.*, p. 434). The latter observer has also found that electrical stimulation of a nerve high up will cause violent spasms in the muscles directly supplied by it, although it may be unable to excite the slightest reflex tremor. On the other hand, Damourette and Pelvette assert a contrary result. Unfortunately, they do not give the details of their experiments. They state, however (p. 247), that if the lumbar plexus of vessels be tied before the poisoning, the fore feet lose their reflex activity before the hinder. There are two possible methods of reconciling their results with those of the other observers. In some way the operation may have interfered with the circulation in the lower part of the cord, and consequently the poison have reached more freely the upper part of it and acted first upon it. Again, if the injection was, as is very probable, thrown into the anterior portion of the body, the poison may have reached the anterior extremities in so concentrated a form as to have acted, as it were, locally upon their nerves and muscles

* From the wording of his memoir, however, it is doubtful whether Purser performed the experiment himself.

The same observers in another portion of their memoir show that the solutions of these salts travel by imbibition; and this and their local action seem to me to be the cause of the differences of experimental results. It seems well established that cutaneous anæsthesia in greater or less degree accompanies the loss of reflex activity; for, as Dr. Purser says, a poisoned animal quite able to jump submits to pinching, pricking, burning, etc., without moving. Eulenberg and Guttman have noticed the same thing in some rabbits. Damourette and Pelvette (*loc. cit.*, p. 247) have noticed a condition in which electrical stimulation of a nerve-trunk produced marked reflex action, although no excitement of the skin supplied by the afferent fibres of the nerve was capable of doing this, showing that the extremities of the sensitive nerves are affected before the trunks. The evidence is, I think, sufficient to prove that bromide of potassium affects all parts of the nervous system of the lower animals, but that the cerebrum, the motor tract of the cord, and the efferent nerves are the last portions to be affected; that the most sensitive to its action is the receptive portion of the cord,—that which receives and transmits reflex impulses,—and next to this, and perhaps almost equally susceptible with it, are the peripheral ends of the afferent nerves.

Upon the cerebrum of the higher animals the bromides undoubtedly exert an influence, and the researches of Professor Albertoni (*Arch. f. Exper. Path. Therap.*, xv. 256) have thrown much light upon the usefulness of the drug in epilepsy. That observer found that when administered to dogs the bromide depresses very markedly the power of the motor zone of the cerebral cortex to respond to stimuli, and to give forth, on decided irritation, epileptic discharges: it was also discovered that this action of the bromide was much more decided when there had been a prolonged saturation of the system with the drug than after a single large or even toxic dose. The intellectual symptoms of bromism show that in man the action of the bromide on the cerebral cortex is more marked than in the lower animals, on account, no doubt, of the higher cerebral development. The drug in other respects acts upon man as upon lower mammals, lowering the reflex excitability of his spinal cord, paralyzing the ends of the peripheral nerves, etc.

According to the researches of Dr. B. Schulze, there is under the influence of the bromide a decided decrease in the elimination of phosphorus,—an indication that the protoplasmic molecular changes in the nervous system are lessened by the drug (*Zeitschrift f. Biol.*, xix. 301, 1883).

Circulation.—It is well established that large toxic doses of the bromide exert a direct paralyzing action on the heart, lessening both the force and the frequency of the beat, and finally causing diastolic arrest.* Dr. J. G. Schouten (*Archiv der Heilk.*, xii. 2, p. 97, 1871; *Schmidt's*

* For experiments upon the isolated frog's heart see *Med.-Chir. Trans.*, 1882.

Jahrb., Bd. cliv. p. 11) found that during the slow injection of a two-per-cent. solution into the vena cava of a rabbit the cardiac systole grew slower, the diastolic pauses longer, and finally the heart stood still, exhibiting only fibrillary contractions of its walls. The same observer is, so far as I know, the only one who has made manometrical studies of the action of small doses of the drug. He found that such amounts of the bromide administered hypodermically or by the stomach always produced increased pulse-frequency with lessened arterial pressure. His experiments were, however, not carried far enough to demonstrate either how these two changes are brought about, or the relations of the drug to the vaso-motor nerves. Much has been predicated upon the theory which asserts that bromide of potassium causes vaso-motor spasm. No decisive proofs have, however, yet been offered of the truth of this favorite dogma. The evidence so far brought forward is as follows: Lewisky found that if the toes of two frogs—one poisoned, the other not—were cut off, the unpoisoned frog bled much more freely than the other. This experiment has been confirmed by Dr. Amory: it, however, evidently does not prove the existence of vaso-motor spasm, but only that of a lessened activity of the circulation, which may be of cardiac origin.

According to Damouratte and Pelvette (*loc. cit.*, p. 249), when the interdigital membrane of the frog is watched during poisoning, there is seen at first very often an exceedingly brief period of increased circulation, but in a very short time the latter becomes much slower. Dr. Meuriot (*L'Étude de la Belladone*, p. 49) asserts that by the aid of the microscope this slowing of the circulation can readily be seen to be due to a contraction of the capillaries, and especially of the small arteries, whose lumen may even be obliterated. Dr. Saisson (*Schmidt's Jahrb.*, Bd. exliii. p. 17) also asserts that he has witnessed a similar phenomenon in the tongue of the frog, and Dr. Hammond and Dr. Amory state that they have seen it in the brain of the dog. On the other hand, Dr. Purser (*loc. cit.*) and Dr. F. B. Nunneley (*London Pract.*, vol. iii. p. 351) assert that the vessels in the frog's web are not affected by bromide of potassium given hypodermically.

My own studies of the action of various poisons upon the vessels of the frog's web have yielded such varying and unsatisfactory results as to make me hesitate in accepting evidence of this nature unless otherwise corroborated. In the absence of manometrical studies, I think the most that can be fairly claimed is that our present knowledge renders it somewhat probable that the salt under consideration is capable of producing vaso-motor spasm. The further deduction that the nervous symptoms induced are secondary to and produced by this spasm is wholly gratuitous, unproved, and improbable. The effect of the bromide when applied locally to the bared nerve demonstrates that it acts directly upon nerve-tissue. Further, the absolute anæmia of the bloodless "salt frog" produces no such nervous symptoms as does even a

non-toxic dose of the bromide; and the direct experiments of Dr. A. Weil (*Reichert's Archiv*, 1871, p. 271) have shown that in the frog the complete abolition of circulation has no effect upon the spinal marrow or upon reflex actions during the first half-hour. The proof is very strong that the drug acts directly upon the nervous tissues.

Temperature.—In warm-blooded animals, toxic doses of bromide of potassium lower very decidedly the temperature. There have been no calorimetric experiments to determine whether this fall of temperature is due to a diminished heat-production or an increase in heat-elimination. The relaxed condition of the vaso-motor system under the influence of the bromide favors the escape of heat, and it is probable that the fall of bodily temperature is due in part or altogether to an excessive loss of heat; especially is this probable since there is a sufficient concord in recent researches upon the action of the bromides to indicate that they increase rather than diminish tissue-change.

Dr. Rabuteau (*Gaz. Hebdom.*, 1869) found that while taking the bromide there was slight lessening in the daily elimination of urea. The experiment was, however, a single one, and the daily dose of the bromide was only fifteen grains, an amount so small as to have no determinate influence. In the *American Journal of Medical Science*, July, 1868, Dr. H. Bill reported the results of an elaborate study of the action of the bromides upon elimination. He found that there was a very decided decrease in the amount of carbonic acid thrown off from the lungs, but that the elimination of urea was not sensibly affected. On the other hand, the quantity of urine was usually increased, the coloring-matters invariably augmented, and the action on phosphoric acid varied: after smaller doses it appeared to be slightly increased. Schulze (*Zeitschr. für Biol.*, vol. xix. p. 301), whose article I have seen only in abstract, in an apparently very careful investigation on his own person, found as the result of the ingestion of one hundred and fifty grains of bromide a day that the urinary secretion was greatly increased, the phosphorus diminished, the sulphur very much increased, and the nitrogen slightly increased. The experiments of Chittenden and Culbert (*Chem. Stud. Laborat. of Yale College*) were also made with great care, and the maximum dose was one hundred and fifty grains a day. The result was diminished excretion of phosphorus, but a pronounced increase of urea. In Chittenden and Culbert's experiments the bromide of ammonium acted like the bromide of potassium, but more powerfully, so far at least as the urea was concerned.

Elimination.—When the blood is charged with the bromide, the salt probably escapes with all the secretions. It has been found by Voisin, Amory, Namias, Bill, etc., in the saliva and in the urine, and by Amory in the perspiration (*Bost. Med. Surg. Journ.*, Oct. 1868). In the body of a man who died while taking it, M. Namias (*Comptes-Rendus*, t. lxx. p. 382) found it in all the liquids, as well as in the brain, liver, spinal cord, lungs, etc. Elimination takes place to a certain extent through

the skin, and to some extent through the intestinal mucous membrane also. P. Guttman (*Virchow's Archiv*, lxxiv.) has recognized bromine in the contents of the acne pustules of bromism. Dr. Bill (*loc. cit.*, p. 25) always detected the bromide in marked quantities in the feces of men taking it; and H. Quinke (*Reichert's Archiv*, 1868, xxxv. 158) found that when forty grains of bromide of sodium were given to dogs with intestinal fistula, two and a half hours afterwards the intestinal juices were free from the bromide, which reappeared in them from three to six hours later. The salt escapes also through the kidneys. The rapidity of elimination seems to vary: thus, Amory recovered one-half of the amount ingested during the first and one-third during the second twenty-four hours, and Mr. Ware (Thesis of Dr. H. P. Bowditch, *loc. cit.*) obtained a little more than half of the amount ingested in the urine of the succeeding thirty-two hours, while Bill was not able to get more than one-eighteenth of it during the first day. Dr. Bill has frequently found the bromide in the urine two weeks after the last dose has been exhibited; and Dr. Rabuteau has seen its presence persist under similar circumstances for a month. Clinical results show that the bromide accumulates in the system, probably in all the tissues, but according to M. Doyon and Professor Cazeneuve it is much more abundant in the nerve-centres than elsewhere (*Lyon Med.*, lx., 1889). Féré and Herbert confirm this great storing up of the bromides in the brain, but also have found the drug in large amount in the liver and kidneys (*Compt.-Rend. Soc. Biol.*, 1891, iii.).*

Summary.—When in sufficient concentration the bromide of potassium acts as a powerful depressant upon all of the higher tissues. It is absorbed rapidly and eliminated in all the secretions more slowly; so that when given continuously it accumulates and causes *bromism*, usually first manifested by fetid breath, acne eruption, sleepiness, muscular relaxation, and general depression. The portions of the human organism most sensitive to its influence are the cerebral cortex, the receptive side of the spinal cord, and the afferent peripheral nerve-endings. Its influence upon the circulation is subordinate. It is, however, a feeble, direct cardiac depressant. The nature of its primary action upon the vaso-motor system remains uncertain, but is pronounced

* It has been claimed (Professor Binz, *London Pract.*, 1874) that the bromide of potassium owes its physiological and therapeutic powers solely to its base. This is plainly not the case, as the bromide is not largely decomposed in the system, and the symptoms caused by it are very different from those produced by carbonate of potassium: in a later publication (*Arch. f. Exper. Path. Therap.*, xlii.) Professor Binz himself has shown that bromine vapor produces in frogs effects in many respects similar to those caused by the potash salt. At the same time it is almost certain that the potash influences the system, and that the whole result is produced by a conjoint action of both ingredients of the salt. G. Koss (*Arch. f. Exper. Path. Therap.*, vi. 43), in three experiments upon man, found decided difference in the results following proportionate doses of bromide and chloride of potassium and of bromide of sodium. He attributes the lessening of reflex activity to the bromine (see also Steinauer, *Virchow's Archiv*, Bd. lix.).

bromism there is in all probability vaso-motor depression, to which would seem to be due the fall of temperature which has been especially noticed in lower animals after toxic doses of the bromide.

THERAPEUTICS.—Bromide of potassium is employed by the therapist to quiet *cerebral excitement* when not inflammatory in its nature; to lessen over-susceptibility of the spinal centres of reflex action, or of the peripheral afferent nerves which lead to these centres; and to subdue nervous excitement of the genital system.

The bromides are contra-indicated by an excessive irritability of the gastro-intestinal mucous membrane; when such condition exists they may provoke exhausting diarrhoea. Great exhaustion, and especially great nutritive exhaustion of the nerve-centres is an absolute contra-indication. Thus, owing to the excitement that attends *confusional insanity*,—i.e., the insanities following child-birth, typhoid fever, surgical operations, etc.,—bromides are frequently administered in large doses, to the great detriment of the patient. I am well convinced that under such circumstances they greatly lower the nutrition and check recovery. In the same way, in *cerebral softening*, *senile dementia*, and allied disorders, they must be used, if used at all, only with the greatest reserve.

There are various forms of *nervous excitement* or unrest, such as sometimes follow excessive intellectual toil, anxiety, and other nervous strain, or occur during convalescence from acute disorder, in which the salt now under consideration is very valuable. The same may be said of some forms of *hysteria*. In some cases of *neuralgia* it undoubtedly affords great relief, but in the majority of cases it fails. It has seemed to me useless in neuralgia dependent upon anæmia or want of power, and my experience agrees with that of Dr. Anstie, that it is especially useful in persons of good nervous power, muscular force, and activity of circulation. As a hypnotic, it is employed in wakefulness from nervous excitement and in *delirium tremens*.

The chief use of the bromide is, however, to lessen reflex activity. It is especially in *epilepsy* that it has attained a well-deserved reputation, doing far more good than all other remedies combined, sometimes effecting cures, more commonly ameliorating the symptoms, but occasionally failing entirely. There is no known method of distinguishing before trial with any certainty in what cases it will do good. Trousseau (*Clin. Med.*, Syd. Soc.) and Bartholow (*loc. cit.*) both assert, however, that it is least efficient in the mild form of the disorder known as the *petit mal*. The most brilliant results have, as a rule, been obtained in cases of not too long duration in which the fits are frequent and severe. The governing principle in its use is to try it in every case, increasing the dose until a mild degree of bromism is induced, and being guided by the results.

The salt is also often efficacious in other reflex spasmodic neuroses: in the vomiting of pregnancy or of uterine diseases; in the convulsions of children; and, according to Dr. J. T. Rothrock, in preventing the

so-called *urethral fever* induced in very susceptible males by the introduction of the catheter or bougie. The physiological action of the salt seemingly indicates that it is of all known remedies the one best suited for the treatment of *tetanus*. Clinical experience certainly accords with this conclusion: in the following table are collected thirty-four cases of tetanus, nearly all traumatic, in which there were but four deaths. Not less than a half-ounce of the salt should be exhibited in the day, and at night chloral should be used as a hypnotic. (See CHLORAL.)

The table contains all the statistical information I have on the subject. Cases not otherwise marked recovered:

In *strychnine-poisoning*, Dr. Saïsson has demonstrated the value of the bromide by experiments on animals, and Dr. Chas. B. Gillespie

* All the cases marked with an asterisk are taken from Dr. Roemer's paper (*St. Louis Med. and Surg. Journal*, 1873). I believe they were all traumatic.

† Since the belladonna probably did as much harm as the bromide did good, this case ought to be excluded.

(*Amer. Journ. Med. Sci.*, Oct. 1870) and Dr. C. L. Bard (*Phila. Med. Times*, June, 1871) have each reported recovery under its use, without vomiting, after the ingestion of three grains of the alkaloid.

In nervous excitement connected with the *genital function*, bromide of potassium is often of great value. When there is actual inflammatory disease, as in *gonorrhœa*, the drug frequently fails to effect the desired end. If, however, there be no organic lesion of the organs or of their nerve-centres, the continued dose will usually succeed to a greater or less extent. I have found the remedy effective in cases of semi-impotence from over-irritability of the organs causing emission too soon during attempted sexual congress. There is abundant evidence as to its value in *nymphomania*. As an adjuvant to other physical and moral measures of relief, the salt may be used with satisfaction in men suffering from masturbation. In nervous symptoms occurring at the time of the menopause or complicating uterine disease, and in the peculiar train of morbid phenomena arising from the forced suppression of the sexual function in vigorous individuals of either sex to whom circumstances have denied marriage, the bromides have almost a "unique power."

Dr. Ch. Bernard (*The Clinic*, Sept. 1874; from *Bulletin Gén. de Therap*) affirms that bromide of potassium in doses of from twenty to forty-five grains a day removes with marvellous quickness *malarial enlargements of the spleen*.

ADMINISTRATION.—I have known half an ounce of the bromide to be taken at once without inducing any serious symptoms; and in severe acute cases, as in tetanus and strychnine-poisoning, it is perfectly safe to administer two-drachm doses at short intervals, as the case may require. Almost all the indications for the use of the bromide are best met by the so-called continuous dose,—i.e., by the administration of so much in the twenty-four hours until an effect is induced. Thus, in epilepsy, half a drachm may be given four times a day, to be increased to one drachm (half an ounce a day) if necessary: although as little of the remedy as will suffice to prevent the recurrence of the fit must be used, yet any amount necessary to do this should be given, unless bromism be produced before the paroxysms are arrested. The remedy must be exhibited, in a solution freely diluted, after meals. In some cases it causes diarrhœa, which may generally be checked with small doses of opium. It is essential in epilepsy and other chronic disorders to persist in the continuous administration of the bromide, it may be for years; and it is remarkable how rapidly the symptoms of long-continued bromism subside upon the withdrawal of the drug.*

* Dr. Ch. Féré claims that many of the disagreeable symptoms of bromism are due to the disturbance by it of the alimentary canal, and are prevented by the daily exhibition of four grammes of beta-naphthol and four grains of the salicylate of bismuth, which doses are borne for months without any inconvenience, usually with much benefit to the appetite and digestion (*Nouv. Iconog. d. L. Salpêtr.*, 1890).

AMMONII BROMIDUM—AMMONIUM BROMIDE. U.S.

According to the U.S. Pharmacopœia, this salt should be prepared by the precipitation of the freshly-made solution of the bromide of iron by water of ammonia, the desired salt remaining in solution. It may be obtained in colorless crystals, but generally occurs in a granular powder, which becomes yellowish on exposure. It has a saline, pungent taste, is readily soluble in water, sparingly so in alcohol. When mixed with mucilage of starch, if chlorine-water be added it becomes yellowish brown; a blue tint would indicate the presence of iodine.

PHYSIOLOGICAL ACTION.—The physiological action of the bromide of ammonium has not as yet been fully investigated; but our present knowledge indicates that while in many points it resembles that of the corresponding salt of potassium, in others it differs essentially from the latter. According to Dr. N. Bistroff (*Reichert's Archiv*, 1868, p. 723), when two decigrammes are administered to a frog, a period of quietude and lessened irritability is induced, which after fifteen or twenty minutes gives place to violent tetanic convulsion. Later, all excitability is lost, so that even burning calls forth no recognition; the frog lies in whatever position it is placed in, the spasms become more violent, and death ensues. Similar phenomena have been witnessed by both Bistroff and Amory (*Bromide of Potassium and Bromide of Ammonium*, Boston, 1872) in the rabbit and the guinea-pig, although in one of Dr. Amory's experiments the guinea-pig died without convulsions having been noted. The curious abolition of reflex action and of sensibility consentaneously with the occurrence of violent convulsions was noted frequently, and death seems always to have resulted from asphyxia. In the experience of Dr. Bistroff, moderate non-fatal doses produced only weakness and uncertain movements in the rabbit.

Bromide of ammonium appears to exert very little influence upon the peripheral motor apparatus. Amory has seen the nerves retain their power of conduction after having been placed in a "strong solution;" and, according to Dr. Bistroff, muscles retain their irritability after soaking five minutes in a ten-per-cent. solution. According to the latter observer, the heart always continued beating after death from the drug, and the heart removed from the batrachian and laid in a ten-per-cent. solution did not in any degree lose its normal activity. Even a twenty-per-cent. solution dropped upon the bared heart produced only a momentary arrest of the ventricular systole. On the other hand, Dr. Purser asserts that the heart is soon arrested in diastole in poisoning by this salt, and that the nerves and muscles also lose their irritability sooner than after poisoning by bromide of potassium.

The subject certainly needs further investigation; but it seems to me most probable that bromide of ammonium exerts less influence upon the muscles than does bromide of potassium, but that in other respects their actions are very similar. The experiments of Amory indicate

that the ammonium salt affects temperature and acts on the capillaries in the same way as that of potassium, and that it is also eliminated in a similar manner. The experiments of Dr. Bistroff show that in the cat, at least, bromide of ammonium has no especial influence, as has been asserted, upon the superior laryngeal nerves.

THERAPEUTICS.—Bromide of ammonium is capable of fulfilling all the indications for which the bromide of potassium is used, and the combination of it with the bromide of potassium was especially recommended in *epilepsy* by Brown-Séquard; although Echeverria (*Epilepsy*, p. 316) asserts that the combination is not superior to the potassium bromide, Professor Clark coincides with Brown-Séquard, and my own experience is very positive that it does not produce so readily acne, rash, and other of the more disagreeable symptoms of bromism. The combination of the bromide of ammonium with antipyrin (thirty to seven) has yielded to me in epilepsy results much superior to those obtained with the potassium salt. The ammonium bromide is a little more irritant than the potassium salt, and should always be given well diluted. It has been especially used by authority in *pertussis*, and by Dr. J. M. Da Costa in *acute rheumatism*. A half-drachm may be given two to four times a day, according to the exigencies of the case.

SODIUM BROMIDE, U.S., closely resembles in appearance bromide of potassium, and has been supposed by Voisin to have closely similar physiological and therapeutic properties. On the other hand, M. J. V. Laborde states (Robin's *Journal*, 1868, p. 560) that in double the toxic dose of bromide of potassium he has found that it does not produce any characteristic symptoms in the frog, the guinea-pig, or the dog, and leaves the animal perfectly healthy.

By clinicians the drug has been used to a considerable extent. Dr. Meredith Clymer (*New York Med. World*, October, 1871) claims that it will arrest epilepsy without producing the unpleasant cerebral symptoms of bromism. He gives twenty grains three times a day. Professor Hammond (*New York Medical Journal*, Dec. 1871) asserts that in epilepsy it is in no wise superior to the potassium salt, but claims that its hypnotic power is much greater. M. E. Decaisne, as the result of the trial of the drug in twenty-seven cases (*epilepsy, chorea, hysteria*), asserts that its action is the same as that of the potassium salt, except that instead of causing diarrhoea it constipates (*Comptes-Rendus*, No. 17, 1870). Notwithstanding this testimony, my own experience is in accord with the physiological teachings, that bromide of sodium, although not free from therapeutic value, is not equal to bromide of potassium in subduing nervous excitation, and is in no wise superior to it.

LITHIUM BROMIDE, U.S., was, I believe, first employed in medicine by Dr. Gibb (*British Association for the Advancement of Science*, 1864), who recommended it as gently tonic and sometimes diuretic. He used it in very small doses. Attention was first called to its em-

ployment in nervous affections by Dr. S. Weir Mitchell, who stated (*Amer. Journ. Med. Sci.*, Oct. 1870), as the result of his experience, that when administered to the amount of half a drachm to one drachm daily, it acts in some cases of *epilepsy* after bromide of potassium has failed, and that it is generally efficient in about one-half the dose of that salt; also that its hypnotic action is much more decided. Professor Clark (*loc. cit.*, p. 111) confirms these observations.*

HYDROBROMIC ACID.—A solution of the gaseous compound of bromine and hydrogen in water was first employed as a therapeutic agent by Dr. Wade (*Peninsular Journ. Med.*, Feb. 1875). Dr. E. T. Reichert (*Bost. Med. and Surg. Journ.*, civ. 505) found that its action upon the nervous system and the circulation is almost identical with that of bromide of potassium; but its influence upon the brain-cortex was not studied. Moderate doses caused some temporary elevation of the blood-pressure, which Dr. Reichert attributes—without, as I think, sufficient evidence—to vaso-motor spasm of peripheral origin. Large doses were directly paralyzant to the heart and to a less extent to the voluntary muscles. Reflex action is suspended by the acid in the frog, and all portions of the spinal cord and nerves are depressed by the poison; but Dr. Reichert presents experimental facts which indicate that the sensory portions of the cord and the sensory nerves are affected before the motor system by hydrobromic acid as they are by the bromides. A long series of trials which I made with hydrobromic acid in the Epileptic Wards of the Philadelphia Hospital determined that the officinal acid in equivalent doses acts very much as does the bromide of potassium, but is distinctly more irritant to the stomach, and less apt to produce an eruption of acne or muscular depression. It may be used alone in the treatment of *epilepsy*, but the combination of it with the bromide has seemed to me the best form of administration: the large dose required, when it is given by itself, in most cases irritates the stomach too much. Under all circumstances it must be well diluted. The officinal *dilute hydrobromic acid* (*Acidum Hydrobromicum Dilutum*, U.S.) represents in each drachm nine grains of bromide of potassium, and may be given in one-half to one-fluidounce doses in a tumblerful of sweetened water.

BROMAL HYDRATE.—This substance, which has been looked upon until recently merely as a chemical curiosity, is formed by the action of bromine upon alcohol, the alcohol being first converted into aldehyde by losing two atoms of hydrogen, and the bromine then replacing the remaining three atoms of hydrogen. The physiological effects of bromal hydrate have been especially investigated by Drs. John G.

* For bromides of zinc and cadmium, see *Le Progrès Méd.*, 1877; for hydrobromic ether, *Robin's Journal*, 1877, *Le Progrès Méd.*, 1877.

McKendrick (*Edinb. Med. Journ.*, July, 1874), E. Steinnuer (*Virchow's Archiv*, Bd. lix. p. 65), Rabuteau (*Gaz. Hebdom.*, t. xliii. p. 681), and Br. Chrostowski (*Hoffmann und Schwalbe's Jahresh.*, 1881, 197). After large doses death occurs in a very few minutes, with contraction of the pupil, dyspnoea, and convulsions. After smaller amounts (three grains in a rabbit of three or four pounds' weight) the symptoms are successively restlessness, dilatation of superficial vessels, contraction of the pupil gradually increasing to a maximum, enormous secretion from the buccal and nasal mucous membranes, greatly increased rapidity of respirations, deepening paralysis, coma, lessened frequency of respirations, anaesthesia, convulsions, and death from failure of respiration. Chrostowski finds that the drug acts directly upon the heart-muscle and excito-motor centres, and much more powerfully than does chloral. The peripheral vaso-motor apparatus was apparently not affected by it. What knowledge we have of its physiological action does not indicate remedial value, and clinical experience with it is still wanting.

BROMIDE OF GOLD.—Dr. Goubert claims that the bromide of gold is the most successful of the bromides in the treatment of *epilepsy* and the more severe forms of *migraine*, having a more permanent effect than the other preparations; and Shtcherbak, in a series of experiments upon the lower animals, found that the gold bromide in doses of 0.1 to 0.2 to the kilogramme had a very pronounced effect in inhibiting the cortical motor centres. The alleged superior activity of the gold bromide can hardly be dependent solely upon the bromine in it, since Shtcherbak found that it was about six times as strong as the bromide of potassium in its action upon the psycho-motor centres, although it contains only 55 per cent. by weight of bromine, whilst the sodium bromide contains 77.7 per cent. and the potassium salt 67.2 per cent. Goubert gives it to the adult in doses of eight milligrammes, gradually increased to twelve, administered in dilute solution.

AMYL NITRIS—AMYL NITRITE.* U.S.

Nitrite of amyl was discovered by the French chemist Balard (*Annales de Chimie et de Phys.*, xii.) in 1844, and the attention of physiologists was called to it in 1859 by Guthrie; but it was not until 1865 that Dr. Richardson, of London, introduced it to the notice of the profession. It is a yellowish, oily, very volatile liquid, of a very penetrating, persistent, fruity odor. It is prepared by the action of nitric acid on amyl alcohol, or, as it is commonly called, fusel oil.

* Barton's ether or tertiary amyl nitrite, a mixture of amyl nitrite and iso-butyl nitrite, has been found by Lauder Brunton and T. J. Bokenham to act very much as does the ordinary amyl nitrite, except that its effects are somewhat more slowly developed and are more permanent. It is not proved to be more stable than the ordinary amyl nitrite and has no advantages over the latter. According to Professor Dunstan, nitrite of amyl of commerce is chemically a mixture of α and β amyl nitrites, iso-butyl nitrite, ethyl nitrite, and propyl nitrite (*St. Bartholomew's Hospital Report*, 28, 1892).

PHYSIOLOGICAL ACTION.—Nitrite of amyl can be absorbed by any surface except the skin, but, on account of its volatility, has hitherto been used in man chiefly by inhalation. Owing to the physical property just mentioned, its action is extraordinarily quick and very transient, it being absorbed and eliminated with great rapidity.

The most prominent symptoms induced when it is inhaled by a man in moderate quantities are a sense of great fulness and distention of the head, amounting at last to severe pain, and accompanied by intense flushing of the face, a deep, labored respiration, and an exceedingly rapid, violent action of the heart. The succession of these phenomena is so rapid that often they seem to be simultaneous; but it is said that the cardiac disturbance is sometimes very distinctly manifest before the other symptoms. It has been noticed by Peck and confirmed by Ladendorff that objects look yellow to a person fully under the influence of the drug. After poisonous doses the symptoms have been great pallor, dilatation of pupils, excessive muscular relaxation, slow, scarcely perceptible pulse, and irregular respiration (*Amer. Journ. Pharm.*, 1881, 137). In a case reported by Dr. Strahan (*Journ. Ment. Sci.*, xxx. 252) a hypodermic injection of ten minims of a ten-per-cent. solution of nitrite of amyl was followed in a minute and a half by two successive furious epileptic convulsions, each preceded by arrest of respiration and of the heart's action. Dr. J. Roesen reports a case in which an epileptic man took upon a full stomach about three drachms of nitrite of amyl (by estimation). The expected epileptic attack did not occur, and the only symptoms which were produced were violent vomiting (*Centralb. für Klin. Med.*, 1888). In George E. Shoemaker's case a drachm caused great weakness, cyanosis, and very feeble, slow, intermittent pulse (*Med. News*, 1893, i.).

In the lower animals the first stage of the action is like that just described in man. After this the breathing becomes violently hurried and panting, progressive muscular weakness and diminution of reflex activity ensue, and finally death from failure of respiration,—sensation and consciousness being preserved almost to the last.

A very peculiar symptom is that a long time before death the arterial blood becomes of almost the same color as the venous blood. Convulsions are sometimes present; but in my experience more often the animal is exceedingly quiet throughout the poisoning.

Elaborate experimental studies of the action of nitrite of amyl upon the circulation in animals have been made by Dr. T. Lauder Brunton (*Journ. of Anat. and Physiol.*, vol. v.,—*Berichte der Muth.-Phys. Classe d. k. sachs. Gesellschaft f. Wissensch.*, 1869), by myself (*Amer. Journ. Med. Sci.*, July, 1871), and by Dr. Amoz-Droz (*Archives de Physiol. Norm. et Pathol.*, Sept. 1873, p. 467). The results are so uniform and in such accord that they must be accepted as proved facts.

Circulation.—It has been found by all three observers just mentioned that, although the pulse is very much increased in frequency sometimes

from the very beginning, the arterial pressure is diminished, and finally is reduced almost to zero, and that the fall of pressure occurs equally after section of the vagi as at other times. As the number of heart-beats in the uninjured animal is increased rather than diminished, while the strength of the individual beat is not perceptibly lessened, it is evident that, at least in the early stages of the poisoning, the diminution of arterial tension is not cardiac in origin, but must be due to dilatation of the capillaries. This conclusion is confirmed by an experiment of Brunton, who found that if the descending aorta was tied up high, no perceptible fall of pressure was produced by the inhalation of the amyl salt until very late in the poisoning, when the heart itself was acted upon by the drug; also by the fact noted by Dr. Ames-Droz and by Gaspy (*Virchow's Archiv*, lxxv. 310), that the vessels of the rabbit's ear and of the frog's web can be seen to dilate when the salt is inhaled.* That dilatation of the vessels takes place in man, as well as in the lower animals, is shown by the flushing of the face, as well as by the enlargement of the retinal vessels, noted by Dr. Chas. Aldridge (*West Riding Lunatic Rep.*, vol. i. p. 187).

An interesting question which here arises is, whether the dilatation is centric, due to an action on the vaso-motor nerve-centres, or peripheral, due to a direct action on the muscular coat of the arterioles. I believe it must be peripheral, and not centric, in its origin, since both in my own experiments and in those of Brunton it occurred after the arterioles had been separated from the vaso-motor centres by division of the cord. This fact appears to prove that the fall of arterial pressure is due to a direct paralyzing action of the drug upon the coats of the arterioles,—a conclusion confirmed by our knowledge of the local action of the nitrite upon muscular tissue.

Bernheim, however, asserts that this cannot be so, and that the dilatation must be solely due to an action upon the vaso-motor centres, because he found that galvanization of the cervical sympathetic still caused contractions in the vessels of the ear of a rabbit to which nitrite of amyl had been given. As pointed out by Pick (*Centralbl. f. Med. Wissens.*, No. 55, 1873), Bernheim's experiment does not warrant his conclusion. It only shows that the muscle-fibres in the walls of the vessels are not so completely paralyzed as to be unable to respond to very powerful stimuli. Dr. W. Filehne (*Pflüger's Archiv*, Bd. ix. p. 478) dissents from the view here taken; but it seems to me that the fall of arterial pressure after paralysis by section of the vaso-motor nerves

* A noteworthy fact asserted by Ames-Droz is that after a long period of dilatation the vessels contract again, whether the inhalation be continued or not. I think the explanation of this is simply that, owing to the volatility of the nitrite, it soon all escapes from the dorsal of lint on which it is placed for inhalation; an explanation strongly confirmed by a statement of Dr. Ames-Droz, that in these cases a new inhalation was followed by dilatation as before. Ames-Droz says only the arterioles dilate, but Gaspy found that both arterioles and veins were affected.

absolutely proves that the drug acts locally upon the arterial coats. It is, however, very probable from the general sedative effect of the drug upon the motor centres that it acts also upon the vaso-motor centres; and when the local flushings caused by small doses of the poison are borne in mind, this probability is greatly enhanced. Filehne affirms that when to animals, whose lungs were exposed, inhalations of the nitrite were given, the change of color was not nearly so great as in the ears, and that if the sympathetic had been destroyed in the neck in a rabbit, and the nitrite of amyl exhibited, the vessels on the unwounded side actually became larger than those of the opposite ear. The answer to these results is, that opening the chest must derange most profoundly the pneumonic circulation, and that all observations upon the comparative size of vessels are very apt to be mere guess-work when the change is slight. Moreover, in Schuller's experiments (*Berlin. Klin. Wochenschrift*, No. 25, 1874), after destruction of the cervical sympathetic in a rabbit, inhalations of the nitrite produced still further dilatation of the vessels of the ear. Dr. Atkinson (*Journ. Anat. and Physiol.*, xxii.) and Dr. D. J. Leech (*Lancet*, 1893, vol. i.) have each found that the nitrite enormously increases the flow of blood serum which is being forced by a steady pressure through the decapitated tortoise, or through a recently excised kidney; a solution 1 in 10,000 had a distinct effect in widening the blood-paths. In conclusion, it seems to me established that nitrite of amyl does act locally on the coats of the arterioles, although it may at the same time influence the vaso-motor centres.

In man the pulse-rate is enormously increased by nitrite of amyl. In animals the amount of the increase varies, but in the higher groups the rule appears to be increase of the pulse-rate, which is especially decided in the dog. Filehne (*Pflüger's Archiv*, Bd. ix. p. 490) has by a single very ingenious experiment apparently shown that the acceleration is due to a depressing influence upon the inhibitory centres. He divided the par vagum in a rabbit, employed an electric current to the severed nerves of sufficient strength to bring the pulse-rate to normal, and found that the amyl salt was powerless to affect the rapidity of the cardiac action. Certain experiments performed by Mayer and Friedrich (*Arch. f. Exp. Path. u. Pharm.*, v. 63) confirm that of Filehne. It is known that sudden asphyxia slows the pulse by exciting the inhibitory centre. Mayer and Friedrich found that this action is prevented by the inhalation of the amyl salt. Then, again, they found that when by compression of the arteries the blood was prevented from going to the head, the nitrite did not increase the rapidity of the pulse, and also determined that the reflex inhibitory slowing of the heart by irritation of a sensitive nerve is prevented by nitrite of amyl. Further, in dogs with a powerful cardiac inhibitory apparatus the primary influence of the nitrite is more marked than it is in rabbits, whose pneumogastries are very feeble. The sudden, thumping action

of the heart so prominent in man when the nitrite is inhaled is therefore probably, at least in part, due to depression of the inhibitory apparatus. There is, however, as pointed out by Dr. Reichert (*N. Y. Med. Journ.*, July, 1881), much reason for believing that in small doses the nitrite acts primarily as a stimulant to the heart. Lauder Brunton long ago discovered that if the aorta be compressed so as to eliminate in great part the influence of the vaso-motor system, the nitrite causes rise in the arterial pressure; and it is perfectly possible for an excessive heart-action to be more than neutralized, so far as the arterial pressure is concerned, by a vaso-motor depression, so that the immediate fall of pressure caused in the normal animal by the nitrite is not proof that the heart may not be stimulated. In Dr. G. A. Atkinson's (*Journ. Anat. and Physiology*, vol. xxii., 1888) experiments, 1 part of the nitrite in 20,000 produced a slight increase in the working power of the cut-out frog's heart (Williams's apparatus); 1 in 10,000 caused a rise for four or five minutes, followed by a fall; smaller and larger amounts than these had either no effect or lessened the heart's action.* It seems, therefore, that our present physiological evidence justifies the belief that very small quantities of nitrite of amyl primarily stimulate the heart, although it is demonstrated that in moderate or large amounts the drug respectively depresses or paralyzes the heart-muscle.

Nervous System.—I have found (*loc. cit.*), as the result of numerous experiments made in the ordinary methods, that the diminution of reflex activity and of voluntary motion which undoubtedly occurs in toxæmia from the agent now under consideration is chiefly spinal in its origin; since after death the nerves and muscles preserve, though in an impaired condition, their functional power. On the motor centres of the cord the nitrite acts as a direct and powerful depressant, at the same time that it exerts a similar but much less pronounced influence on the nerves and muscles, decreasing, but not destroying, their functional life. The diminution of reflex activity is never preceded by a stage of functional excitement. In some animals convulsions do occur, especially when the drug is administered by inhalation; but they are in all probability cerebral, not spinal, and due to the asphyxiating influence of the poison. Over the sensory nerves and centres nitrite of amyl has but little power. They are among the last portions of the body to be affected, sensation being intact until near death: so that the drug is in no sense an anæsthetic. Mayer and Friedrich assert that at first nitrite of amyl increases the rapidity and depth of the respiration by stimulating the respiratory centres. Whether this be or be not correct, it is certain that later the respiratory centres are greatly depressed, the breathing becoming both slow and shallow, and death finally occurs from paralytic asphyxia of centric origin.

* There is, however, still much uncertainty about the matter. Dr. D. J. Leech affirms that 1 in 10,000 always quickens and weakens the beat of the isolated frog's heart in a Roy apparatus (*London Lancet*, l., 1893).

Urine.—Elimination.—Dr. F. A. Hoffmann found (*Reichert's Archiv*, 1872, p. 747) that in the rabbit a hypodermic injection of 0.111 to 0.113 gramme of the drug is enough to cause diabetes. If twice this amount of the amyl salt is used, the sugar becomes very abundant in the urine, and continues to be present for from twelve to thirty hours. Contemporaneously with the elimination of sugar there is a great increase in the amount of the urine. In a patient under my care, to whom the salt was given very freely, at no time could sugar be detected in the urine: so that glycosuria is probably induced only by toxic doses. The nitrite is probably oxidized in the system, at least in part, as F. Rohrmann (*Zeitschr. f. Physiolog. Chemie*, v. 233) has found that when nitrite of potassium is administered to the lower animals the nitrate appears in the urine.

Local Action.—Nitrite of amyl causes a progressive loss of functional power in every highly-organized tissue with which it comes in contact. Nerve-centres, peripheral nerves, muscles of organic and voluntary life, all succumb to it alike.* If the contact be not continued too long, the tissue may recover even after a total suppression of its function,—a proof that the poison exerts no destructive chemical or devitalizing influence upon the tissues, such as that of sulphuric acid or veratria.

Temperature.—Nitrite of amyl, in whatever way exhibited, if given in sufficient amount, reduces most remarkably animal temperature. I have seen a pigeon perfectly conscious although its temperature had been brought down by this agent some 13° F. This influence is as marked in fever as in the normal condition of the animal, and is independent of the nerve-centres, occurring after section of the cord, and even after death in those cases in which post-mortem rise or continuance of high temperature normally takes place. I have also experimentally determined that it is associated with diminished excretion of carbonic acid. It must therefore be due to a direct arrest or check of tissue-changes or oxidation within, or without, the blood. The mouth-temperature in man is certainly sometimes elevated by the inhalation of nitrite of amyl, but the rise is a very temporary one. W. A. Manassein and N. Sassezki (*St. Petersb. Med. Wochenschr.*, 1879, iv. 392) found, in a number of studies upon normal and fevered men, that while the peripheral temperature was at first increased the rectal temperature was always reduced, and after a time even the surface of the body grew cooler. The maximum reduction was reached in one to one and a half hours, and in a case of fever amounted to 3° C.

The vapors of the nitrite have a very marked influence over oxidation outside of the body, as is shown by many facts, of which it is only necessary here to cite the extinguishment of glowing phosphorus by

* According to Dr. Leech (*London Lancet*, i., 1893), 1 in 1000 of amyl or sodium nitrite is fatal to voluntary muscles. The involuntary fibres are even more sensitive.

a few drops of the amyl salt diffused through the jar. It cannot be doubted that within the economy the same thing occurs. If, however, the arrest of oxidation were complete, instant death from suffocation would result. The true explanation of the symptoms evidently lies in diminution, not destruction, of oxidation.

When an animal inhales nitrite of amyl, the arterial and venous blood soon become of a nearly uniform hue, which resembles somewhat that of normal venous blood, but is quite distinct from it, having a chocolate tint. Moreover, this chocolate-colored blood does not assume the arterial hue when shaken with the air. Dr. Arthur Gamgee (*Philos. Trans.*, 1868, p. 589) discovered that as the chocolate color is assumed by the blood the two spectrum bands of the oxyhæmoglobin disappear and are replaced by new bands, nearly, but not exactly, in the place of those of acid hæmatin. If ammonia be added to the chocolate blood, the color changes back to a blood-red again, and simultaneously the spectrum lines regain their normal position. If a reducing agent, such as sulphide of ammonium, be added to the chocolate blood, it is able to deoxidize the oxyhæmoglobin, but, before doing so, evidently removes it from union with the nitrite, since the new bands disappear and those of oxyhæmoglobin reappear in the spectrum before the lines of the reduced hæmoglobin manifest themselves. Dr. Gamgee also found that the nitrite of amyl blood had lost its power of absorbing oxygen, or of yielding oxygen to the air-pump, and that carbonic oxide gas added to the blood did not expel oxygen from it. Having thus determined that a new compound is formed in the blood by the nitrite, Dr. Gamgee finally succeeded in obtaining it in a crystalline form. As he always upon analysis found the nitrite in this compound, he considered it to be a nitrite-oxyhæmoglobin. Recent researches have, however, shown that the spectrum of this new compound is identical with that of methæmoglobin of Hoppe-Seyler (*Zeitschr. f. Physiol. Chem.*, Bd. ii., Bd. iii. 54), so that the identity of the two substances is very probable.

These facts do not seem to me to prove that nitrite of amyl entering into the blood-vessels at once overpowers the hæmoglobin of the blood-corpuscles and checks all oxidation. As already stated, the experiments of Dr. Gamgee showed conclusively that this new compound yields up its oxygen to reducing agents. Further, the doctor found that when the nitrite blood was brought into contact with prepared guaiacum-paper it still ozonized it, though not so actively as normal. It is evident that the blood-corpuscles retain to a greater or less degree their power of yielding up ozone to bodies desiring it, and are capable of exerting at least this portion of their respiratory function: further, when this ozone is given up and the oxyhæmoglobin changed into hæmoglobin, so far as our present knowledge goes, the hæmoglobin must absorb more oxygen before it can reunite with the nitrite. Evidently, then, absorption of oxygen must take place; evidently the blood-corpuscles must perform their respiratory function; but evidently also they are greatly crippled

and impaired in the rapidity and ease of its performance. Hæmic respiration is, in other words, greatly interfered with, but not abolished.

The accord of the results of this chemical investigation with those arrived at by a purely physiological study of the drug is very striking and very beautiful, both teaching the same thing,—lessened but not absolutely arrested oxidation.

Having ascertained the existence of diminished oxidation in poisoning by nitrite of amyl, the temptation is very strong to attribute all the symptoms produced by it to this arrest. I do not, however, think that this *post hoc propter hoc* argument is justifiable, for the following reasons. In the first place, nitrate of potassium and other nitrates, according to Dr. Gamgee, act in the same manner upon the blood, yet the symptoms caused by them are very different from those caused by nitrite of amyl. In the second place, when arrest of oxidation is caused by deprivation of oxygen (see article on Nitrous Oxide) the symptoms are very different, the brain and consciousness being always affected before the centres of reflex action, whereas under the influence of nitrite of amyl the contrary occurs. In the third place, other substances, such as toxic doses of alcohol, check oxidation, but do not cause the same symptoms as does the drug under consideration. The obvious inference seems to me to be that nitrite of amyl acts directly upon the nerve-centres, independently of its influence on the blood.*

In sufficient dose the nitrite is poisonous to the white corpuscles; Atkinson has found that 1 in 1000 kills the corpuscles in fifteen to twenty minutes.

Summary.—The dominant physiological action of nitrite of amyl is upon the spinal cord and the circulation. Under its influence arterial pressure falls from paralysis of the blood-vessels, chiefly as the result of a direct action upon the muscles in their walls. At the same time the heart is, directly or indirectly, enormously stimulated, the number and force of its contractions being increased, this period of stimulation after moderate doses gradually subsiding into the normal state, but after toxic doses passing into one of cardiac paralysis, with a final arrest in diastole, which is due to a direct action upon the heart-muscle or contained ganglia. Paralysis of motion and loss of reflex activity, prominent phenomena of advanced poisoning, are due to a direct action upon the motor side of the spinal cord. Death results finally from paralysis of the respiratory centres. By a direct action upon the red blood-corpuscles the hæmoglobin is converted into a new compound, met-hæmoglobin. The fall of the bodily temperature is probably the result of lessened oxidation. Locally applied in concentrated form, nitrite of amyl paralyzes all higher tissues.

* I have left this paragraph as in previous editions, although the interesting paper of Professor C. Bins (*Virchow's Archiv*, civl., 1889) suggests that methæmoglobin may be an active agent in nitrite poisoning. He asserts that in the bloodless frog of Cohnheim the nitrites produce a profound narcosis, during which neither circulation nor respiration is affected.

THERAPEUTICS.—The results of the clinical use of nitrite of amyl are in accord with what has been said of its physiological properties. Its administration in *angina pectoris* appears to have been first suggested to Dr. Brunton (*Lond. Clin. Soc. Rep.*, vol. iii.; *Lancet*, July 27, 1867) by the sphygmographic tracings giving evidence of arterial spasm in a case of that disorder. As the pathology of these cases of heart-pang is not definitely made out, it seems useless to speculate how the nitrite acts in many cases;* but there is abundant evidence of its value in relieving almost instantly agony which has resisted all other treatment. This appears also true whether valvular disease or merely functional disorder exists. In cases of advanced fatty degeneration or of very great dilatation of the heart, I think its use would be attended with some danger, owing to its effect upon the heart-muscle. Dr. Foster (*Brit. Med. Journ.*, 1874, i. 77) has found the drug of great service in a case of *cardiac disease* in which there was aortic insufficiency with excessive hypertrophy and severe frontal headache.

Its physiological action would indicate that it should be of service in all cases of spasm of the capillaries, of the bronchial tubes, and of the muscular system generally. Accordingly, Dr. Oskar Berger (*Allgem. Medicin. Central-Zeitung*, May, 1871) and others have used it with very good effect in *migraine* with evident capillary contraction. In *asthma* my own experience of several cases coincides with that of various physicians, that it will often instantly arrest the paroxysm,† especially in those instances in which there are no secondary lesions, such as emphysema and dilated heart.

The convulsion of *epilepsy* is, according to the present theory, due to a vaso-motor spasm at the base of the brain, to correct which the amyl salt would seem to be indicated, as it also is by the mere existence of the convulsion. In advanced stages of the paroxysm it must, however, be used with caution, on account of the obscuring of its early effects by the symptoms of the disease. In the *status epilepticus*, when there is an almost indefinite repetition of the fits, the remedy may be of great use in stopping them. When there is a notable interval in ordinary epilepsy between the aura and the convulsion, the latter can usually, if not always, be entirely prevented (Dr. S. Weir Mitchell, *Philad. Med. Times*, vol. v. p. 553): the patient should carry a small vial containing a few drops of the drug, and inhale it at once whenever the aura is felt.

Dr. Mitchell also calls attention to the value of the nitrite as an aid in diagnosing those occasional cases of nervous disorder in which petit-mal is simulated by attacks really due to passing congestion of the nerve-centres. He asserts that in these cases nitrite of amyl instead of arrest-

* For a case of failure, see *Lancet*, August, 1867.

† For remarkable cases, see *British Medical Journal*, Sept. 30, 1873; also *Butler's Compendium*, part xiii., Jan. 1874.

ing the paroxysm increases its intensity. Dr. Wm. F. Jenks has found the nitrite efficient in arresting *puerperal convulsions*, but dangerous on account of producing uterine relaxation and post-partum hemorrhage,—a result to be expected from the known physiological action of the drug (*Phila. Med. Times*, 1872, vol. ii. p. 404). In *tetanus* nitrite of amyl would seem to be indicated as a spinal sedative, and as controlling excessive tissue-changes and consequent rise of temperature. It has been used, so far as I know, in only three cases (*Lancet*, 1871; *Phila. Med. Times*, vol. v.), all of which recovered, two with the amyl salt alone and the other with it and chloral. In nervous *dysmenorrhæa* the remedy was first used successfully by Dr. Fucel; it has been highly commended by Dr. Mary Putnam-Jacobi (*N. Y. Med. Rec.*, Jan. 1875) and by Dr. P. Peck (*Deuts. Arch. Klin. Med.*, xvii. 143). Two to six drops should be given when the pain comes on, and repeated *pro re nata*. In *cholera* nitrite of amyl has been tried without, that I can perceive, even a good theoretical reason, and has not seemed to be of service (*Lond. Med. Rec.*, vol. i.). Dr. V. Urbantschitsch has employed it with various results in various irregular cases of *vaso-motor* disturbances, in intermittent *coryza*, *migraine*, etc. (*Wiener Med. Presse*, 1877). I have seen it used in a number of cases of *intermittent fever*, with the invariable result of putting an end to the chill and of not affecting the hot stage.

The increased cardiac action produced by inhalation of the nitrite has led to its employment as a cardiac stimulant, and there is now much clinical evidence in favor of its employment in cases of sudden *heart-failure*, as from "*fatty heart*" (Osgood, *Amer. Journ. Med. Sci.*, 1874, xx. 58) and from *hemorrhage* (Madden, *Lond. Practitioner*, xii., 1874),* and in cardiac failure during *anæsthesia*. In Dr. Reichert's experiment the blood-pressure and pulse-wave, depressed almost to zero by the ethylene bichloride (*Phila. Med. Times*, 1880), were immediately and markedly increased by the nitrite; but in the series of experiments made by myself with chloroform no such effect was obtained, and certainly the zone between stimulation and depression of the heart by the nitrites is so narrow that the greatest care must be exercised in employing the drug in *anæsthetic heart-failure*.

The physiological action of the remedy would very strongly indicate it as an antidote in *strychnine-poisoning*. No case of its use for this purpose in man has come to my knowledge, but the experiments of Dr. St. Clair Gray on rabbits (*Glasgow Med. Journ.*, 1871, p. 188) yielded very favorable results. In two rabbits to each of which ten drops of the nitrite and half a grain of strychnine were given together subcutaneously, no decided symptoms whatever were induced; while one-quarter grain of the alkaloid alone frequently caused death in a single convul-

* Consult also *Phila. Med. Times*, iv.; *Psychol. and Med.-Surg. Journ.*, Feb. 1875; *London Lancet*, May, 1875; *Med. Times and Gaz.*, Dec. 1874; *Brit. Med. Journ.*, 1877.

sion. These results have been confirmed by Dr. Hobart A. Hare (*Boston Med. and Surg. Journ.*, Nov. 1884). During the paroxysm of cramp asphyxia it was found necessary to give the nitrite hypodermically, on account of the lack of respiratory movement.

ADMINISTRATION.—As already stated, the method of administration usually employed hitherto is inhalation, from one to three or five drops being placed on a handkerchief and held near the mouth or nose, the handkerchief being removed so soon as a sense of fullness of the head is experienced. I have given it by the mouth, dropped upon a lump of sugar and taken instantly in doses of two or three drops. There is not at present sufficient evidence to enable us to decide as to the maximum amount of the drug which it is safe to give. In a case of cholera (*Lond. Med. Record*, Oct. 1873), Dr. D. B. Smith exhibited hypodermically two drachms in the course of an hour and thirty-six minutes without inducing any serious symptoms, and a dose of a dessertspoonful has been recovered from, emetics being given (*Amer. Journ. Pharm.*, 1881, 137). Used with care, the nitrite, although a very rapidly-acting and powerful agent, seems to be safe, since I have never seen either in man or in the lower animals any sudden or unexpected action,—any influence out of proportion to the amount given. It must be borne in mind that the symptoms generally increase in intensity for a minute or two after the withdrawal of the drug.*

It is not to be doubted that all of the nitrites depend for their physiological activity on their acids, and that most of them have similar physiological properties. This has been shown to be true of nitrite of ethyl (Dr. Richardson, *Brit. and For. Med.-Chir. Rev.*, July, 1867, and Dr. J. D. Leech, *Med. Chron.*, vol. ix., 1889). Dr. Leech claims that the nitrite of ethyl has the great advantage over the amyl salt of some permanency of action, the effect of the single dose lasting from a half to two hours. He highly commends in *asthmatic bronchitis* a solution, which he states to be stable, composed of three parts of the nitrite, five of glycerine, and ninety-two of absolute alcohol; dose, thirty to ninety minims.

POTASSIUM NITRITE,† U.S., has been studied by Prof. E. T. Reichert (*Amer. Journ. Med. Sci.*, lxxx. 180) and Dr. G. A. Atkinson (*Journ. Anat.*, xxii., 1887-88). Doses of six to ten grains in man sufficed to raise the pulse to 110 or 120, with flushing of the face and intracranial throbbing; the symptoms usually began in twenty minutes and lasted several hours, and were in no case disagreeably severe. Eructations of a phosphorus-like taste were nearly always present. Ten to fifteen grains have pro-

* For a case in which an epileptic convulsion followed a hypodermic injection of one minim of the nitrite, see *Journ. Ment. Sci.*, xxx. 252. It is doubtful whether the convulsion was caused by the nitrite.

† For a paper on the theory of the action of the nitrite of sodium by Professor Binz, see *Arch. f. Exper. Path. u. Pharm.*, xlii. 138.

duced complete muscular relaxation, livid lips, headache, etc., lasting three hours (*Lancet*, 1883, ii. 766). In a very elaborate series of experiments upon animals, Dr. Reichert found that the effects of nitrite of potassium and of nitrite of sodium upon the blood, heart, and nerve-centres are indistinguishable from those of nitrite of amyl except in being much less rapid and more permanent. In cases of *angina pectoris* the duration of the influence of these nitrites makes them especially desirable, and they will probably in practice be found superior to the amyl salt. Twenty grains of the commercial nitrite of sodium have been given without serious effect, but of a pure article, either of the sodium or the potassium nitrite, the dose is three grains; five grains have often produced serious symptoms (see *London Lancet*, 1883, ii. 945). At present a pure article is commonly kept in good drug-stores. The dose may be repeated every two hours cautiously.

NITROGLYCERIN is the most powerful of the nitrites. The symptoms which it causes in man are giddiness, constriction, or other abnormal sensations in the head, often amounting to severe headache, choking in the throat, sometimes nausea, and rapid cardiac action, with lessened arterial pressure. After toxic doses there is great failure of the heart's action. A single drop of a one-per-cent. alcoholic solution has produced insensibility, and in the case of Mr. Field, who took two drops, loss of consciousness and of the pulse at the wrist were complete (see *Brit. Med. Journ.*, 1880, i. 406). Dr. J. Noer (*Therap. Gaz.*, 1887, 459) attributed the following symptoms in a woman to the use of ten-drop doses of the alcoholic solution of nitroglycerin. The pulse was slow, intermittent, and very irregular, the pupils dilated, the urine scanty and containing considerable pigment. There was also pain in the region of the heart, intense headache, sense of constriction around the forehead, and great weakness of the muscles. Drs. Lauder Brunton and Tait (*St. Barthol. Hosp. Rep.*, xii. 140) have found that upon blood-coloration, arterial pressure, nerve-centres, and muscles nitroglycerin acts very much as does nitrite of amyl. This similarity of action between nitroglycerin and the nitrites has been recently confirmed by Dr. Murrell and Dr. Matthew Hay (*Lond. Practitioner*, xxx. 422), also by A. Henocque (*Comptes-Rendus Soc. de Biolog.*, 1883, v. 669), and is remarkable, as nitroglycerin may be regarded as nitrate of glyceryl. It has been shown, however, by Hay, that during its alkaline decomposition it yields nascent nitrous acid, and it can scarcely be questioned that this acid is developed in the blood and acts upon the system.

The effect of nitroglycerin is certainly more prolonged than that of nitrite of amyl. According to Professor Korczynski, the maximum effect of a dose in man is reached in from three to fifteen minutes, while all effects disappear in three-quarters of an hour (*Schmidt's Jahrb.*, xciii. 132). Within the last few years nitroglycerin has been used

quite largely in the London hospitals, with asserted excellent results, in *neuralgia* and in *angina pectoris*. The practice has found imitators on both continents. The reports are almost universally favorable in regard to the action of the drug in *cardiac failure*, and in *asthma*, *uræmia*, and *puerperal eclampsia*, and other affections in which experience has shown that nitrite of amyl is of value.

Dr. Trussowitsch (*St. Petersb. Med. Wochenschr.*, No. 1, 1887) states that he has obtained excellent results from the use of nitroglycerin in *neuralgia*, *headache*, *dizziness*, and other irregular nervous symptoms, and even in general failure of health in persons whose weak, small pulses and peculiar pallor marked the habitual fulness of the venous system. He is in the habit of commencing with half of the ordinary dose in these cases, increasing it if the results are favorable.

Nitroglycerin is kept in the drug-stores in one-per-cent. alcoholic solution, the dose of which may be set down as a half-drop, increased to two or three drops if necessary. It is said that this solution is not explosive, but that, unless care be exercised in manipulating it, headache and other unpleasant symptoms are apt to be produced. Mr. Martindale has shown that nitroglycerin is soluble in cacao butter, and it has been proposed to administer it in the form of chocolate lozenges.

VALERIANATE OF AMYL has been introduced to the medical profession by Dr. W. F. Wade (*Brit. Med. Journ.*, i., 1874), who appears to consider its therapeutic properties about the same as those of valerianic acid. He makes a compound spirit by adding one part of the valerianate to nineteen of alcohol, and to each ounce half a minim of acetate of amyl. Of this he gives eight drops in an ounce of water. The preparation is no doubt an active one, but probably possesses other properties than those of valerianic acid. According to G. Bruel (*L'Ether Amyl-valérianique*), valerianate of amyl is capable of dissolving three times as much cholesterin as is chloroform, and may be employed with the greatest advantage for the purposes of dissolving biliary calculi. He also asserts that it is a valuable hypnotic and antispasmodic, useful in such spasmodic diseases as *asthma*, *hysteria*, *hepatic*, *renal*, and *intestinal colic*, etc.

LOBELIA. U.S.

The leaves and tops of the indigenous herb *Lobelia inflata*. The dried plant has a slight irritating odor and a taste at first scarcely perceptible, afterwards burning, acrid, and attended with a flow of saliva. Professor Proctor, of this city, discovered the alkaloid *lobeline*, which was long believed to be liquid, until Drs. J. U. and G. G. Lloyd obtained it in broad, colorless, odorless, and tasteless crystals. The Messrs. Lloyd also assert that there is a second alkaloid in lobelia, but the researches of Dreser (*Archiv f. Exper. Path.*, xxxvii., 1889) make it seem probable that this second alkaloid is a derivative from lobeline.

PHYSIOLOGICAL ACTION.—The symptoms produced by large doses of lobelia in man are nausea, soon followed by violent vomiting, accompanied with intense prostration, as is shown by feeble pulse, cold sweats, pale skin, and great muscular relaxation. Purging may or may not occur. Numerous cases of fatal poisoning by it have been recorded. The symptoms are those above mentioned, intensified; in some cases vomiting does not occur, and it is especially under these circumstances that fatal effects have been noted. Burning in the fauces and œsophagus, and epigastric distress, in addition to the intense prostration, bordering upon collapse and finally merging into complete collapse, with coma, stupor, muscular tremblings, and in some cases convulsions, precede the fatal termination.

For our knowledge of the physiological action of lobeline, we are indebted to the researches of Dr. I. Ott (*Bost. Med. Surg. Journ.*, 1875; *Phila. Med. Times*, vi.), Dr. Afanasiëff (*Lond. Med. Rec.*, Aug. 16, 1886), and H. Dreser (*Archiv für Exper. Path.*, Bd. xxvi., 1889). When given to the frog, lobeline produced failure of voluntary movement, with distinct loss of co-ordination and disturbances of respiration. Unless the dose has been too large, there is primary increase of the reflex activity, which, however, sinks below the norm until it is lost. All experimenters seem to be in accord in concluding that the final paralysis is due to a direct paralyzing action upon the motor nerves.

Berstein some time ago called attention to the fact that the spinal cord of the frog is usually supplied with blood from the anterior spinal artery, and that by thorough and complete section of the cord the lower segment is cut off from the general circulation. Experimenting in accordance with this, Dreser found that the increased reflex activity produced by lobelia was confined to the anterior section of the cord and tributary muscles, and concludes that lobeline is a direct spinal stimulant.

In mammals, the symptoms produced by lobelia are: slowing and irregularity of the respiration; progressive failure of the muscular power; violent vomiting in those animals which have the power of vomiting; dilated, fixed pupil; convulsive seizures; fall of the bodily temperature, and death from asphyxia, the heart continuing to beat after the failure of respiration, the dominant physiological action of the drug being its influence upon the respiratory centres.

Respiration.—The recent researches of Dreser seem to show that both the respiratory centre and the vomiting centre in the medulla oblongata are primarily excited by lobeline; hence the vomiting, and hence, also, the increase not only in the rate of the respiration, but in the amount of air taken in and out from the lungs, as observed by Dreser. This condition of excitement is followed by paralysis of the respiration, which after very large doses may come on abruptly, even within two or three minutes after the injection of the poison. According to Dreser, the paralysis of the motor nerves, noted in the frog, is of little importance in the mammal, the respiratory centre being so susceptible

to the drug that it is paralyzed before the nerves. Dreser also found that there is a peripheral palsy of those vague filaments which have influence upon the bronchial muscles.

Circulation.—According to Dr. Ott, when lobeline is injected into the jugular vein of the rabbit there is immediate fall of the arterial pressure, followed by a rise of pressure, and this, in turn, by a second fall. In both of Ott's experiments, and also in those of Afanasieff, rise of arterial pressure was noted as occurring in curarized animals, so that it would appear that the rise is not secondary to asphyxia. Ott, in his experiments, found that the rise of pressure was very pronounced after section of the cord between the occiput and atlas, which would seem to prove that it is due to a direct action either upon the heart, or upon the muscles of the arterial coats. Ott found that in nicotinized rabbits no rise of pressure occurred, and hence concludes that the rise of pressure is due to peripheral vaso-motor stimulation. It would seem, however, probable that the drug may act upon the heart itself, as Afanasieff has found that small doses in frogs increase the power of the cardiac contractions (if the dose be large enough, the first stimulation is followed by a fall of power, with periodically recurring arrest, ending in final diastole). The important practical fact is that the action of lobelia upon the circulation is subordinate to its influence upon the respiration. The final fall of pressure is probably in part cardiac, in part vaso-motor.

Toxicology.—The symptoms of lobelia-poisoning have been sufficiently described. The treatment should consist in washing out the stomach with plenteous draughts of a warm solution of tannic acid, in the free exhibition of opium and of alcoholic and ammoniacal stimulants, and in the use of external stimulation by dry heat, frictions, mustard, etc., precisely as in poisoning from *veratrum viride*.

Therapeutics.—Lobelia has been used as an emetic; but its depressing effects are so severe as to forbid such employment of it. It has also been employed to relax spasm in various affections, as in pertussis, tetanus, epilepsy, chorea, convulsions, but has been superseded by more efficient and less dangerous remedies. The only affection in which I have ever seen lobelia do any good, and in which I think it ought to be used, is *asthma* or *acute bronchitis* with *bronchial spasm*; the good it does is probably due to an action upon the motor filaments of the pneumogastric nerve in the lungs. An *infusion* (Si to Oj) has been strongly recommended as a local application in the eczema produced by the *rhus toxicodendron*, or "poison-vine." The powder is very rarely used; the dose as an emetic is twenty or thirty grains. The dose of the *tincture* (*Tinctura Lobeliae*—20 per cent., U.S.), as an expectorant, ten to twenty minims; in the paroxysm of asthma, f3i to f3ii every half-hour until nausea is induced. The dose of the *fluid extract* (*Extractum Lobeliae Fluidum*, U.S.) is, as an expectorant, one to five minims; as an emetic, fifteen minims. According to Dr. S. Nunes (*Schmidt's*

Jahrb., Bd. cccxix.), from five to forty centigrammes of lobeline may be given in the day, but in any case the first dose should not exceed one-fortieth of a grain, to be increased *pro re nata*.

GELSEMIUM. U.S.

The root of *Gelsemium sempervirens*, the yellow or Carolina jessamine, a beautiful climbing plant of the Atlantic Southern United States, distinguished by its large, axillary, very fragrant, clustered blossoms and perennial dark-green leaves. The very light, fibrous, dirty-yellowish root has a bitterish taste, and contains an alkaloid, *Gelsemine*, in combination with *Gelseminic Acid*, both discovered by Professor Wormley.

PHYSIOLOGICAL ACTION.—There is a wide range of susceptibility in man to the influence of gelsemium, some individuals being profoundly influenced by a dose which has no perceptible effect upon another person. After the smallest active dose (five to fifteen minims of the fluid extract), the only symptom is languor; with it may be a little lowering of the force and frequency of the pulse. When a somewhat larger amount is ingested, to the languor are added dizziness and disturbance of vision, with, in some cases, a pain over the brows. Ringer and Murrell state that the pupil is contracted, but this is probably an inconstant result. After toxic doses of the poison the muscular weakness is extreme, and in several cases (*Bost. Med. and Surg. Journ.*, 1869, iii. 185; 1879, ci. 18) the flexors of the arms have been especially affected. The disturbance of sight is now very marked; double vision, or partial or even complete blindness, may exist; the pupil is widely dilated and immovable; the external rectus muscle is weakened, sometimes sufficiently to produce a marked internal squint; the eyelid droops, and is raised with difficulty or falls in paralytic ptosis. If the patient is able to walk at all, the gait is staggering; the jaw drops, articulation fails; the general sensibility is much impaired; respiration slow and labored; the pulse feeble and thready; the skin bathed in a cold sweat; the bodily temperature greatly lowered. Sometimes drowsiness is felt after moderate doses of the poison, but consciousness may be preserved in the midst of very severe symptoms, although in all the fatal cases I have met with it was lost before death. The drug acts very promptly, symptoms usually appearing in about twenty minutes after its ingestion, and beginning to subside in two or three hours.

Gelsemium produces in the lower animals symptoms similar to those which it causes in man, with the exception that convulsions are very generally developed. They are not always present, but they have been observed in the frog, pigeon, cat, rabbit, and dog. The loss of voluntary power precedes the convulsions, and in the careful experiments of Ringer and Murrell (*Lancet*, 1876, i. 83) upon frogs it was found that the cord was rapidly exhausted by repeated irritations, so that convulsions could not at once be induced. Professor Bartholow states that in the rabbit, cat, and pigeon the convulsive movements are backward, sometime

amounting to complete somersaults. The close study of the action of gelsemium is best made by taking up the various systems in rotation.

Nervous and Muscular Systems.—The retention of consciousness until very late in the poisoning, both in man and in the lower animals, shows that the drug has very little power over the higher cerebrum, although the drowsiness and the final loss of consciousness prove that it is not entirely devoid of such influence. The two most prominent symptoms caused by the drug are the convulsion and the paralysis. The first question to be determined is whether the convulsion is cerebral, spinal, or peripheral. That it is not cerebral is proved by its occurrence in the pithed frog (Ringer and Murrell, *Lancet*, 1876, i. 83), and below the point of section in mammals with divided spinal cord (Taylor, *Richm. and Louisv. Med. Journ.*, 1875, p. 606); that it is not peripheral is proved by its taking place in the posterior extremities when the lower aorta is tied before the poisoning (Ringer and Murrell). The cause of the convulsion at present remains inexplicable. The theory of diminished resistance (see p. 209) can hardly be received, because in the careful experiments of Dr. Ott (*Phila. Med. Times*, vol. vii. p. 289) a condition of exaggerated reflex activity was proved to precede the convulsive state. Ringer and Murrell conceive that there are present in gelsemium two active and antagonistic substances, one a tetanizant,* the other a paralyzant; but in their own experiments, and in those of Dr. Ott, gelsemine believed to be pure produced convulsions. Nevertheless, it is notable that Ott found the acid so much stronger in convulsive action than the alkaloid as to suggest that Ringer and Murrell's supposition is correct.

The paralysis in poisoning by gelsemine is evidently spinal in its origin, as its development is not affected by tying an artery before poisoning so as to protect a limb (Bartholow, *Practitioner*, vol. v. p. 202; Ringer and Murrell, *Lancet*, 1875, ii. 908), and as the afferent and motor nerves and muscles preserve their functional activity until death (Ott, Bartholow,† Ringer and Murrell). It is a matter of some importance, in explaining the spinal action of the drug, to determine its influence upon the different portions of the cord. Dr. Bartholow says that "it acts also on the sensory portion of the cord, producing at last, complete anaesthesia; but this effect in warm-blooded animals and in man is toxic only, and follows the paralysis of the motor functions."

* In confirmation of this, A. R. Cusebny (*Arch. für Experim. Pathol.*, 1892, xxxi.) finds that there are two bases in gelsemium, to one of which he gives the name of *gelsemin*, the other *gelseminin*. Gelsemin he finds produces in the frog violent spinal excitement with increase of the reflexes, followed by paralysis due to an action upon the nerve-endings. Gelseminin is the more active of the two, producing a paralysis by direct action upon the spinal centres and having also a curare-like paralytic influence upon the nerve-trunks.

† Dr. Roberts Bartholow affirms (*Practitioner*, v. 203), "This experiment indicates that gelsemium destroys the excitability of the sensory nerve before the motor;" but his conclusion seems hardly warranted by his premises, and in his treatise on therapeutics he distinctly shows the central origin of the paralysis.

This may be correct, but, so far as I know, has not been experimentally proved.

Respiration.—Gelsemium usually kills by a paralysis of respiration. According to the researches of Burdon Sanderson and of Ringer and Murrell (*Lancet*, 1876, i. 490, 560), immediately after the ingestion the extent of the respiration, but not its rate, is increased; very shortly, however, both rate and depth enter a condition of progressive palsy ending in death. The respiratory changes are the product of a direct action upon the respiratory centres, being uninfluenced by previous section of the vagi.

Circulation.—The action of moderate doses of gelsemium upon the circulation is not very marked. That in toxic amounts it depresses both the pulse-rate and pressure is abundantly shown by the symptoms of poisoning in man, and by Dr. Ott's experiments upon animals (*Phila. Med. Times*, v. 691). As the pulse-rate and pressure were reduced in these experiments after previous section of all the cardiac nerves and of the spinal cord, it is evident that the poison exerts a direct influence upon the heart. How far the vaso-motor centres are influenced by the drug has not been accurately determined.

Eye.—The influence of gelsemium upon the organ of vision is very decided. Ringer and Murrell affirm that decided non-toxic doses of the drug cause contraction of the pupil. However this may be, marked dilatation of the pupil is a very constant symptom in the poisoning. It has also been discovered by Ringer and Murrell, and confirmed by Mr. John Tweedy (*Lancet*, 1877, i. 833), that the local application of gelsemine to the eye produces violent mydriasis, with paralysis of accommodation. This indicates very strongly that the dilatation is produced in poisoning by the drug through an influence exerted upon the peripheral nerve ending in the eye. The palsy of the external rectus and the ptosis indicate that such action is paralytic, so that it is a probable conclusion that peripheral oculo-motor paralysis is the cause of the dilatation of the pupil. The falling of the jaw and the loss of the power of articulation indicate that all the motor nerves of the head are acted upon by the poison.

Summary.—The characteristic symptoms of gelsemium-poisoning are progressive muscular weakness, double vision, dilated pupils, squint, ptosis, dropping of the jaw. The chief physiological action of the remedy seems to be depression of the spinal cord, including the respiratory centres. The effect of the remedy upon the circulation is not pronounced, but toxic doses depress directly the heart.

THERAPEUTICS.—Gelsemium was originally employed as an arterial sedative and febrifuge in the *malarial fevers* of the South, and subsequently in other *sthenic fevers*. It appears in some way to depress the bodily temperature, but certainly possesses no controlling influence over the arterial system at all comparable to that of *veratrum viride* and *aconite*. Dr. Bartholow commends it highly, as in *pneumonia* and *pleu-*

ritis; its influence for good in these disorders would seem, however, to be chiefly associated with its power of lessening the rapidity of respiration and increasing the tendency to perspiration. It does not appear probable that any advantage to be derived from it will counterbalance the dangers attending its employment in the large doses required. In *asthma*, *spasmodic laryngitis*, *whooping-cough*, and *nervous cough*, in which it is also recommended by Professor Bartholow, its employment seems more plausible, as in these cases there is a distinct spasmodic element. The testimony to its value is most marked in cases of *trigeminal*, *ovarian*, and other *neuralgias*. How it does good in these disorders is as obscure as is the nature of the neuralgias, and in my hands it has usually failed. The marked effect of the drug upon the facial nerves would appear to indicate its employment in facial neuralgias, and especially in facial spasmodic affections. In acute *mania* the drug may be employed in full doses as a calmative.

Mr. Tweedy has drawn attention to the local use of gelsemium (*Lancet*, 1877, i. 832) by the oculist as a substitute for atropine, claiming that it may be employed with equal surety as a paralyzant of accommodation and dilator of the pupil, and that it possesses the very great advantage of its influence going off in a few hours. Thoroughly to paralyze accommodation, however, it must be used freely; as he states, "To insure paralysis of accommodation within three hours, a solution of at least eight grains [gelsemine] to the ounce must be used every fifteen minutes for the first hour, and every half-hour afterwards." Employed in this way, I should think there would be some danger of general poisoning by absorption.

TOXICOLOGY.—Dr. I. Ott (*Phila. Med. Times*, v. 693) has collected six cases of fatal poisoning; a teaspoonful of the fluid extract being the smallest amount that has caused death in the adult. Professor Wormley believes that his chemical examinations have shown that in one fatal case the fluid extract ingested could not have contained more than one-sixth of a grain of the alkaloid.

The treatment of gelsemium-poisoning should be conducted on general principles. Our present knowledge does not indicate that morphine and gelsemium are physiological antagonists, but Dr. Geo. S. Courtright asserts that they have such relation, and details a case in which recovery occurred after the ingestion of from one to two teaspoonfuls of the tincture, one and one-half grains of morphine having been given hypodermically and one grain by the mouth (*Cincinnati Lancet and Observer*, 1876, p. 963).

ADMINISTRATION.—The dose of the fluid extract (*Extractum Gelsemii Fluidum*, U.S.) is five minims every two hours until constitutional effects are produced; of the tincture (*Tinctura Gelsemii*—15 per cent., U.S.), ten to twenty minims.

TABACUM—TOBACCO. U.S.

Tobacco in its various forms is so familiar an article of every-day life that I shall not enter upon any description of it. Its sole active principle is an alkaloid, *Nicotine*, it having been proved that the alleged alkaloid *Nicotianin* has no existence. *Nicotine*, when pure, is a colorless, transparent, volatile liquid, of a strong tobacco-like odor and a persistent burning taste. It is freely soluble in water, which it absorbs readily and largely from the air. Its salts are crystallizable with difficulty.

PHYSIOLOGICAL ACTION.—Upon those persons who are not habituated to its use, tobacco acts as a very powerful depressant, producing horrible nausea and vomiting, with giddiness and a feeling of intense wretchedness and weakness. If the amount taken has been large, to these symptoms are added burning pain in the stomach, purging, free urination, extreme giddiness passing into delirium, a rapid, running, and finally imperceptible pulse, cramps in the limbs, absolute loss of muscular strength, a cold, clammy skin, and finally complete collapse, terminating in death.

Nicotine produces, when taken in minute quantities, symptoms sufficiently similar to those just detailed. Thus, Schrott (quoted by Stillé and by Krockner) found that in doses of from one-thirty-second to one-sixteenth of a grain it caused an intense burning in the fauces, œsophagus, and stomach, which diffused itself as a sense of heat all through the body, and was followed by giddiness, nausea, and some vomiting, with a rapid, feeble pulse, diarrhœa, intense muscular weakness, laborious respirations, icy extremities, partial loss of consciousness, and other indications of impending collapse. Reil (*Journ. f. Pharmacodyn.*, Bd. ii. p. 203) took one-seventh of a grain of the alkaloid, with the production of burning in the throat and stomach, headache, a feeling of heat in the head, increase of pulse-rate sixteen beats, muscular weakness, and a sense of oppressed respiration. In one or two instances, violent muscular tremblings have come on shortly after the ingestion of the poison, and ended in general clonic convulsions. In large amounts nicotine acts with lightning-like rapidity. Thus, in a case of suicide, in which an unknown amount was taken (*Taylor's Medical Jurisprudence*, vol. i. p. 393), the man dropped instantly to the floor insensible, gave a deep sigh, and was dead in about three minutes.

When a minute drop (gtt. $\frac{1}{10}$) of nicotine is administered to a frog, the first evidences of local irritation are succeeded in a few seconds by tetanic cramps, in which the front legs are laid forcibly along the side of the trunk, and the feet bent over the back. This position is said by Krockner to be characteristic of nicotine- or conine-poisoning, and to be due to the extensor muscles being more powerfully contracted than the flexors. When very minute doses are administered, according to Vulpian, this general tetanus is replaced by muscular tremblings and irregular convulsions. After a short time the motor excitement in

either case is succeeded by complete muscular relaxation, which, if the dose has been toxic, soon passes into general paralysis, and finally death by failure of respiration, the heart continuing to beat after breathing has ceased. The symptoms which the poison produces in mammalia are exactly parallel with those which it causes in the batrachian. The evidences of the pain produced by the intense local irritation caused by the poison are soon succeeded, after a small dose, by muscular tremblings and irregular voluntary movements, during which the animal often falls through weakness, and which rapidly give way to violent tetanic and clonic convulsions; to these succeeds an intense calm, in which voluntary movement is largely but not altogether abolished. In the first part of this stage external irritation still produces convulsions, but later it is without influence. The urine and feces are usually voided, and sometimes vomiting occurs. The pupils, at first narrowly contracted, now (Krocker) dilate slightly, but not to the normal point. The breathing, which at first was rapid and shallow, becomes distant and fuller, the peripheral capillaries are relaxed and full of blood, and finally paralysis deepens into death. After death the venous system is usually found engorged. The physiological action of the alkaloid can best be studied in detail by taking up the various systems separately.

Nervous and Muscular Systems.—Upon the *cerebrum* nicotine probably exerts very little direct influence. The convulsions* are certainly of spinal or peripheral origin, since they occur, according to the experiments of Krocker, in frogs whose cerebrum has been extirpated. That they are not peripheral is proved by the experiments of Vulpian (*Comptes-Rendus de la Soc. de Biol.*, 1859, p. 151), who found that cutting off all the arterial communication between the hind legs of the frog and its trunk did not affect the development of the convulsions, when the animal was poisoned with nicotia. This has been confirmed by Krocker, who also found that if the nerve-trunk of a limb be divided the convulsions cease in that limb. The convulsions are, therefore, spinal, and the first stage of nicotine-poisoning is one of spinal excitement. The question here naturally arises, Is the paralysis of the second stage due to spinal depression? There is not yet sufficient evidence to warrant a positive decision as to how far the cord is involved in the paresis, but Krocker is probably correct in believing that it is at least to some degree affected, since he found that tying the arteries of a limb so as to preclude the poison from reaching the nerves did not prevent the limb from lying limp and powerless during the paralytic stage.

The action of the poison upon the peripheral nerves has been definitely settled by the experiments of Vulpian, of Rosenthal (*Centralbl. f. Med. Wissen.*, 1863, p. 738), of Krocker, and of Hare, all of whom have

* P. Uspensky has found (*Reichert's Archiv*, 1868, p. 525) that these convulsions are not influenced by artificial respiration.

found that the functional activity of the motor or efferent nerves is more or less completely abolished by the poison. By tying the artery low down in one leg of a frog, so as to protect the peripheral endings, applying the galvanic currents some distance above this point, and comparing the results with those obtained by galvanizing unprotected nerves, Krocker determined that the peripheral endings were paralyzed sooner than the nerve-trunks, although the trunks themselves were finally affected. The peripheral nerve-endings appear to be at first excited, as Vulpian and Krocker have found that muscular tremblings are not prevented by section of the supplying nerve, and that they even occur in the curarized frog. These fibrillary contractions also occurred when the alkaloid was injected into a leg whose connections with the trunk had been cut off by a tight general ligature. According to Vulpian and Rosenthal, the sensory or afferent nerves retain their activity to the last; but Lautenbach believes that they are affected (*Phila. Med. Times*, May, 1877). J. N. Langley and H. K. Anderson, in a series of experiments on various animals, found that the nerve-cells in the ciliary and superior cervical ganglia connected with the iris are paralyzed before the nerve-endings in the third, fourth, and sixth nerves in the eye-muscles, and that these in turn yield to the action of the poison before the nerve-endings in the skeletal muscles (*Journ. Physiol.*, vol. xiii., 1892). Upon the voluntary muscles all observers are in accord in asserting that nicotine exerts no influence.

Circulation.—When nicotine is added to freshly-drawn blood, the latter assumes a peculiar dark hue, and the microscope shows that the red corpuscles rapidly disintegrate. In nicotine-poisoning the blood is, however, not perceptibly affected. The amount of the alkaloid necessary to take life is exceedingly small, and although the death by asphyxia causes the vital fluid to be everywhere dark, yet most observers state that under the microscope the corpuscles are normal. According to Krocker, the dark blood assumes an arterial hue when shaken with the air. This is confirmed by Dr. H. A. Hare (*Fiske Fund Prize Diss.*, Phila., 1885), who, however, found that the spectrum of the hæmoglobin is altered, so that it is probable that the red corpuscles are somewhat affected by the poison: indeed, Hare affirms that after very large doses changes in the corpuscles can be detected by the microscope.

As was first discovered by Traube (*Allgem. Med. Central-Zeitung*, 1862), the circulatory phenomena produced by the injection of moderate doses of nicotine are, first, slowing of the pulse and force of the arterial pressure; second, rise in the arterial pressure, the pulse remaining slow; third, increased rise of the pressure, with marked acceleration of the pulse; fourth, fall of pressure, with continuance of rapid pulse; and at last complete lowering of the arterial pressure, with slowing of the pulse. Traube asserts that if the pneumogastrics be cut during the period of slow pulse, the pulse will become at once very rapid; but he also affirms that previous section of the par vagum

does not prevent the slowing of the pulse, and in this is confirmed by Wertheimer and Colas (*Archiv. d. Physiol. Norm. et Path.*, 1891). Schmiedeberg (*Berichte u. d. Verh. d. k. sachs. Gesells.*, 1870) states that a previous use of atropine prevents the slowing of the pulse.* In the experiments of Tugenhold (reported by Rosenthal) upon frogs, the slowing of the heart amounted at times to the complete diastolic arrest; and Basch and Oser (*Wien. Mediz. Jahrb.*, 1872), as well as Wertheimer and Colas, have noticed a similar occurrence in mammals. Rosenthal found in the frog that previous division of the par vagum did not prevent this diastolic arrest, but very large doses of curare did.

Although Traube's statement, that section of the pneumogastric nerve during a period of slow pulse in nicotine-poisoning is followed by a rapid pulse, seems at present inexplicable, the theory urged by Rosenthal, that nicotine slows the pulse by stimulating the extreme cardiac inhibitory apparatus, is very probable; the setting aside of the action of the nicotine by curare and by atropine being, under this supposition, due to the paralyzing influence of these agents upon the intra-cardiac inhibitory apparatus. The final rise of the pulse-rate in nicotine-poisoning appears to be due to paralysis of the peripheral inhibitory nerve or ganglia, since Rosenthal found that late in the poisoning the most powerful stimulation of the vagi fails to affect the heart, whilst Baldi (*Archiv. Ital. de Biolog.*, xv.) has shown that the local application of nicotine to a vagi-trunk produces paralysis of the nerve without any perceptible previous stimulation.

The rise of the arterial pressure produced by nicotine seems to be, at least in part, of cardiac origin, as Rouget (*Journ. d. l. Physiol.*, 1860), confirmed by Wertheimer and Colas, has found that nicotine re-enforces the energy of the cardiac muscle and prolongs its irritability. In conformity with this is the statement of Dr. W. T. Benham (*West Riding Lunatic Asylum Rep.*, vol. iv., 1874), that the local application of the alkaloid to the cut-out heart of a rabbit will bring back systolic contractions after they have ceased. Further, Wertheimer and Colas have noticed in the mammal that even after complete section of the spinal cord nicotine is still apt to increase arterial pressure. That, however, the rise is not altogether cardiac in origin seems to be shown by the experiments of Wertheimer and Colas, in which it was proved that as the pressure rises the spleen and kidneys decrease in size; or, in other words, that the capillaries of the spleen and kidneys contract. It is probable that the final failure of pressure is largely due to widening out of the blood paths, since Rosenthal and other observers have noticed increase in the size of the blood-vessels of the rabbit's ear during the later stage of the poisoning.

Pupil.—When exhibited in a moderate toxic dose, or when applied

* A fact discovered by Wertheimer and Colas, that nicotine still further increases the rapidity of the atropinized heart, has been shown by these authorities to be due to a peripheral action, as it has not been prevented by previous extirpation of the cervical sympathetic ganglia.

directly to the eye, nicotine produces a very marked contraction of the pupil. If, as is asserted by Krocke, the alkaloid contracts the pupils of cut-out eyes, it is evident that the action is a local one. Hirschmann (*Reichert's Archiv*, 1863) has found that galvanization of the divided cervical sympathetic fails to cause dilatation of the pupil. Krocke, in later experiments, has confirmed this in regard to large doses of the drug, but has found that myosis occurs long before the sympathetic is unable to dilate the pupil. This fact renders it probable that the alkaloid paralyzes the peripheral endings of the sympathetic; but it is barely possible that it induces a spasm of the fibres supplied by the oculo-motor so powerful that the sympathetic is unable to overcome it. Be this as it may, it is very probable that the sympathetic paralysis, if it exists, is associated with oculo-motor spasm; but at present we have not sufficient evidence to warrant any definite conclusion.

Abdominal Organs.—Nasse found in his experiments (*Beiträge zur Phys. der Darmbewegung*, Leipzig, 1866) that injections of nicotine into the jugular vein produced a tetanic contraction of all the intestines, which was not affected by section of the vagi or by compression of the abdominal aorta; even the splanchnics were unable to exercise their inhibitory influence, either because they were paralyzed or because the spasm was too intense for them.

In what way the poison is eliminated has not, that I am aware of, been determined, but it very probably escapes with the urine, since, according to Claude Bernard (*Substances Toxiques*, p. 410) the rapidity of the secretion of that fluid is increased.

THERAPEUTICS.—Tobacco has been employed in past times in a large number of diseases, but has almost passed out of sight as a therapeutic agent, and there are only two indications which it is capable of meeting. These are as follows:

To relax spasm.—Imperfect as is our knowledge of the physiological action of tobacco, so far as it goes it indicates very clearly the great power of the drug in quieting violent muscular spasms. The frightful nausea and vomiting which it is so apt to induce, and the occasional excessive violence of its action, have led to its being superseded by less disagreeable and more controllable remedies. It is still, however, employed occasionally in *tetanus*, with asserted good results. In *spasmodic asthma*, if the patient be not accustomed to smoking, one or more strong cigars will very often at once end the attack, or perhaps abort one which is threatening. In *strychnine-poisoning*, tobacco has been used in several cases successfully.

To alleviate pain.—Taken internally, tobacco has no powers of relieving pain at all commensurate with the danger attending its use, and it should never be employed for that purpose. It is different with its local use: thus, it is often added with great advantage to ointments in the case of painful *hemorrhoids*; and in *pruritus* a strong wash of tobacco affords one of the surest modes of relief. It must never be

forgotten that its external employment has led to the most serious and even fatal poisoning.* For this reason tobacco ought never to be employed, as it formerly was, to kill vermin on the person.

TOXICOLOGY.—A large number of deaths have resulted from the medicinal use of tobacco, Husemann stating (*Handbuch der Toxicologie*, vol. ii. p. 483) that no less than ten fatal cases have been caused by tobacco enemata alone. Dr. Copland has seen a clyster containing half a drachm produce death (*Dict. of Pract. Med.*, art. *Colic*). Even smoking has caused an acute fatal poisoning. Melsens affirms that the smoke of half an ounce of strong tobacco contains sufficient nicotine to prove fatal† In the only case of criminal nicotine-poisoning on record, an unknown amount of the alkaloid was forced into the mouth of the victim, causing death in from three to five minutes (*Ann. d'Hygiène*, 1861, ii.). The treatment of tobacco-poisoning consists in washing out the stomach, the free administration of ammonia and alcohol, the hypodermic use of moderate amounts of strychnine, and the employment of such external measures as dry heat, rubbings, etc. If these fail, artificial respiration should be maintained. The excessive use of tobacco produces in some persons serious nervous disturbance, such as insomnia, irritability, general feebleness; the most characteristic symptom is a peculiar irregularity of the heart's action, often accompanied by distinct intermissions. Amaurosis is also sometimes present. Jonathan Hutchinson affirms (*Med. Times and Gaz.*, 1884, i. 40) that he has seen this amaurosis recovered from by the use of opium and champagne without the abandonment of the habit of smoking.

ADMINISTRATION.—The dose of tobacco in substance is usually stated to be five grains, which may be given in infusion. In strychnine-poisoning and tetanus the remedy should be exhibited at short intervals until constitutional symptoms are induced.

CONIUM. U.S.

The U.S. Pharmacopœia recognizes only the full-grown fruit, gathered while green, of *Conium maculatum*. The plant is umbelliferous, a native of Europe, but naturalized in the United States. The dried leaves have a strong heavy odor, increased by the addition of an alkali, and resembling somewhat that of mice. They are bi- or tripinnate, and very much incised. The fruits are one to two lines long, roundish-ovate, striated, with five crenated ribs on the outer sides of the easily-separable halves; the odor is that of the leaves. The active principle is *Conine*, a yellowish, oily, liquid alkaloid, highly volatile, of a strong odor similar to that of the urine of mice, and of a very acrid taste. It is freely soluble in alcohol and in ether, and slightly so in water, with which it forms a

* For a number of cases, see Stillé's *Therapeutics*, vol. ii. p. 374.

† The activity of tobacco-smoke is connected with the presence in it of other substances than nicotine (see *Comptes-Rendus*, ac. 1838). A. P. Fokker found a large proportion of carbonic oxide, and asserts that animals immersed in the smoke die of poisoning by that gas.

hydrate, and it coagulates albumen; when exposed to the air it undergoes decomposition, becoming first brown, afterwards resinous; heat accelerates the change.

PHYSIOLOGICAL ACTION.—The chief symptom produced in man by conine when taken in doses just large enough to impress decidedly the system is great muscular weakness or languor, with some disorder of vision, and giddiness. On attempting to walk, the patient suffers from a feeling as though his feet were made of lead, and staggers or falls from the refusal of his knees to support him. There is an intense desire to lie quiet in the horizontal position, and, as the eyelids are especially affected, the eyes are kept shut. In some subjects these symptoms are preceded or accompanied by burning in the mouth or fauces, nausea, and even vomiting, besides heat of head, often with a sense of weight or pressure, or even severe frontal pain. The disorder of vision is apparently due in great part to a sluggishness and finally to a paralysis of accommodation. The experiments of Poeblmann (quoted by Husemann, *Die Pflanzenstoffe*, p. 269) show that very grave symptoms may be induced and yet the pupil remain natural; but sooner or later, as the drug gains power over the system, it probably always dilates. The pulse is first diminished, afterwards increased, in frequency. In decided poisoning by conium the symptoms are probably simply those already mentioned, intensified. I have met with accounts of but four fatal cases of such character. In one, that of the mistress of Dr. Hermann Jahn, killed in a few minutes by from ten to fifteen drops of the alkaloid (quoted by Husemann, *Die Pflanzenstoffe*, p. 269), violent palpitation of the heart is said to have been a prominent symptom. The chief symptom in the second case (*Edinb. Med. and Surg. Journ.*, 1845) was universal paralysis, with total failure of voluntary movement and of the voice before consciousness was lost. Convulsive movements were present very late in the case. Sensation appeared not to be lost until death was at hand.

The third case was in the person of a medical electrician, suffering from blepharo-facial spasm, who took, beginning four hours after the last of a previous series of divided doses of a fluid extract amounting to one hundred and eighty drops, at 4.10, 4.40, and 5.15 p.m. fifty minims (one hundred and fifty in all) of "Squibb's fluid extract." The first dose produced dizziness and muscular relaxation; the second, great muscular weakness, inability to stand, and thickening of speech, without relief of the spasm; the third, immediately, some nausea, and tremors about the chest. At 6.10 there were nausea, intense muscular weakness, partial ptosis, diplopia, and great difficulty of speech; the pulse was 60. Shortly after this he became unable to speak or to swallow. He made signs for electricity, and, on being asked whether the chemical or the faradic current, indicated the latter, and also the place of application of the electrodes, but was unable to hold one of the latter. Shortly after this, on being raised up, he dropped dead. (*The Sani-*

(arian, June, 1875). A fourth case, in which a child five years old died of asphyxia preceded by coma and paralysis as the result of taking a drachm of chloroform-water containing five grains of the extract of conium, is recorded in *Pharm. Journ. Trans.*, xvi. 102.

In mammals conium produces symptoms parallel with those observed in man, and it probably acts similarly upon all vertebrates. In frogs convulsions are rarely if ever present; in birds they are occasionally so; in mammals they are more frequent,—thus, Ihmsen saw them in twelve out of twenty-three experiments; they are chiefly clonic, but tonic spasms do occur in the hind legs. As the legs are usually affected before the arms in man, so in quadrupeds the hind extremities are usually paralyzed first. Sensibility is maintained to the last. The respiration is generally much affected, and the heart continues to beat after its cessation.

The occasional salivation and excessive sweating of conine-poisoning indicate that the alkaloid escapes with all the secretions; but the kidneys are undoubtedly the chief channel of elimination. Zaleski and Dragondorff have found it abundant in the urine during the first twelve hours of the poisoning; Prevost has seen the urine of poisoned animals cause in a frog the characteristic general palsy, and in a doubtful case this physiological test might decide the diagnosis.

Nervous and Muscular Systems.—All observers agree that the chief symptom produced by conine (i.e., the paralysis) is not due to any direct influence upon the muscles, which, indeed, preserve perfectly their contractility up to death. In 1856, Kölliker (*Virchow's Archiv*, Bd. x. p. 228) announced that the failure of motion in conine-poisoning is caused by a direct action of the alkaloid upon the *efferent* or *motor nerves*. He first experimentally found that in frogs killed by the drug the application of the galvanic current to a nerve fails to induce contractions in the tributary muscles. He then tied the aorta in such a way as to cut off the supply of blood to the hind extremities, and found that after voluntary motion had ceased in the fore legs, and even after galvanic stimulation of the anterior nerves had lost its influence upon the muscles directly supplied by those nerves, irritation of the same anterior nerves produced reflex contractions in the hind legs, showing that the anterior afferent nerves and the spinal cord still retained functional activity after the loss of it in all those efferent nerves reached by the poison. After repeating these experiments a number of times, he drew the conclusion already given.

His experimental results have been confirmed by Funke (*Berichte über die Verhandl. der k. sachs. Gesellsch. d. Wissensch. zu Leipzig*, Bd. xi. p. 23, 1859), by Guttmann (*Berlin. Klin. Wochenschr.*, 1868, quoted by Husenmann), and by MM. Pelvotte and Martin-Damourette* (*Gazette*

* M. Tiryakan (*Compt.-Rend.*, lxxvi. 1344) has affirmed that absolutely pure conine does not affect the nerves, but M. Prevost (*Arch. Physiol. Norm. et Path.*, 1880, vol. vii.) has shown that chemically pure bromohydrate of conine has this action.

Méd., 1870, quoted in *Archives Gén.*, 6e sér., t. xvi. p. 88). The latter observers extended the series by severing in a frog all the tissues at the upper part of the thigh except the nerve, and found that when a batrachian so prepared was poisoned with conine, after the paralysis was complete in all portions of the body to which the poison had access,—after stimulations of the poisoned nerves were powerless to excite contraction in the tributary muscles,—the leg which had been protected from the action of the conine upon it responded not only to irritations applied to its nerve, but also to stimuli placed upon distant portions of the body. These same observers also noted that when conine and strychnine were given simultaneously to a frog from one of whose sciatic nerves the circulation (i.e., direct access of the poison) was cut off in either of the manners spoken of, they produced by their conjoint action a commingling of paralysis in all other parts of the body with violent tetanic spasms in the protected leg,—a commingling explainable only on the supposition that the conine paralyzed all the motor nerves to which it had access through the circulation. Since B. F. Lautenbach (*Phila. Med. Times*, vol. v.), Verigo, A. W. Hofmann, Professor Prevost, H. Schultz (*Schmidt's Jahrb.*, cxlix. 16, cxcv. 119), and Fliess (*Arch. f. Physiol.*, 1882, p. 111) have confirmed these experiments, it must be considered as an established fact that the chief physiological action of conine is as a *paralyzer of the motor nerves, and primarily of their peripheral filaments*.*

It has generally been believed that conium does not affect the sensory nerves; but in 1875 (*Bull. Thérap.*) M. Gubler called attention to its local influence in benumbing the cutaneous sensibility, and Lautenbach (*Proc. Acad. Nat. Sci.*, Phila., 1875) found that when he tied the abdominal aorta and left axillary artery in the frog, and then injected a new dose of conine into the abdomen, irritation of the leg whose nerve was not protected from the poison failed to cause reflex movements at a time when irritation of the protected nerves produced reflex actions in distant parts of the body. These experiments seem to show that the alkaloid is a paralyzant to the sensory nerves; but it certainly acts upon them much less powerfully than it does upon the motor nerves.

The exact influence of conine upon the *spinal cord* cannot yet be considered absolutely determined, but it is most probable that the poison has a feeble depressant action. Dr. Verigo (*Schmidt's Jahrb.*, cxlix. 16) asserts that it is a powerful spinal depressant, and MM. Pelvotte and Martin-Damourette (*Arch. Gén.*, 6e sér., t. vi. p. 89) say that it acts as an excitant. Dr. Lautenbach (*Proc. Acad. Nat. Sci.*, Phila., 1875), in carefully investigating the subject, failed to obtain, under any circumstances, evidences of excitement of the cord; he did succeed in pro-

* H. Tiryakan (*Étude expérim. et chir. sur la Coniine*, Paris Thèse, 1878) endeavors to show that this action of conine is due to an impurity, and not to the alkaloid; but this is *a priori* exceedingly improbable, and Professor Prevost (*Arch. de Physiol.*, Nov. 1880, 40), using the same preparation as did Tiryakan, has found that the motor nerves are affected.

ducing loss of reflex activity where the nerve was protected by tying the artery in the limb, but, as in all but two of fifty-two experiments the reflexes in the protected limb were not greatly reduced until just before death, it is plain that any action upon the spinal cord is unimportant and dominated by the more powerful influences of the poison. The experimental results obtained by Drs. A. D. Davidson and D. Dyce Brown (*Med. Times and Gazette*, July, 1870), which have been cited as favoring the absurd theory of Dr. Harley that the corpora striata are especially affected by the drug, depended no doubt upon an arterial anomaly said to be common in the leg of the cat.

According to the experiments of Lautenbach (*loc. cit.*, p. 451), the convulsions of hemlock-poisoning are cerebral, since, in a number of cases, after division of the cord they were confined to those muscles supplied by nerves arising from that portion of the spinal marrow above the section.

The retention of consciousness and of the mental faculties so late in the course of poisoning by conine proves that the drug has but little influence upon the cerebral hemispheres.

Pupil.—The pupil is generally dilated by conine; but both Von Praag (*Journ. für Pharmacodyn.*, Heft i. p. 31) and Verigo assert that the phenomenon is not constant, at least in animals. The ptosis of conium-poisoning indicates that the dilatation of the pupil is due to oculo-motor paralysis. The known action of the drug upon nervo-trunks indicates that this paralysis is peripheral,—a conclusion corroborated by the experiments of Dr. I. Hoppe (*Die Nervenwirk. der Heilmittel*, Heft i., Leipzig, 1855) and of Lautenbach, each of whom found that when conine is dropped into the eye of an animal it causes at first contraction, apparently due to the intense irritation, and afterwards dilatation, of the pupil.

Temperature.—Verigo, Von Praag, and others affirm that lethal doses of conium cause a decided lowering of temperature; but Lautenbach asserts that the drug decidedly increases the temperature both when in therapeutic and when in toxic doses.

Circulation.—No sufficient investigation has as yet been made upon the action of conine upon the circulation. Lautenbach states that the arterial pressure falls immediately after the injection of conine, and afterwards rises far above the normal point, and that the pulse is at first accelerated, but afterwards retarded. The secondary rise of pressure was probably due to asphyxia. The primary pulse-acceleration is explained by the observation of M. Pelénard, confirmed by M. Prevost, that the pneumogastrics are paralyzed before the motor nerves. M. Prevost finds that the heart itself is scarcely affected at all by the poison.

When locally applied in a concentrated condition, conine probably is fatal to all the more highly organized tissues. Certainly Christison (*Edinburgh Philosoph. Trans.*, vol. xiii.) proved this to be so in regard to

the muscles, although these organs are not influenced by conine taken internally. Upon the mucous membranes it acts as an intense irritant.

Summary.—The chief symptom of poisoning by conium is a failure of voluntary and involuntary movement, the result of a progressive paralysis of the motor nerves. The cerebrum is not affected, hence consciousness is preserved to the last. The pupil is dilated by a peripheral paralysis of the oculo-motor nerve. The sensory nerves and the spinal cord are probably feebly depressed. It is probable that the alkaloid does not directly act upon the circulatory apparatus except to paralyze the pneumogastrica.

THERAPEUTICS.—The paralytic action of conium naturally suggests its use in spasmodic affections; and accordingly it has been tried in *chorea*, in *paralysis agitans*, in *whooping-cough*, and in other diseases of similar nature. Although it seems not to have met with continued favor, and is but little used, it may be employed when life is threatened by the mere convulsive actions, as it will suspend these for the time being. If Dr. Harley's views as to its physiological action be correct, it ought to be especially useful in all motor disturbance connected with irritation at the base of the brain. Clinical proof is, however, nearly as scarce as physiological in this matter.

In *maniacal* and *hysterical excitement*, the drug in full doses is said to produce a condition of calm and relaxation which is highly favorable; and in the treatment of the insane, conium is very much used by some alienists (*Amer. Journ. of Insanity*, April, 1873).

Conium has also been employed to relieve pain. As a deobstruent and alterative it has been very largely used, both locally and internally, in *neuralgia* and *sciatica*, with asserted occasional success, in *cancerous* and other tumors, in *chronic glandular enlargements*, in *swollen joints*, and in various *chronic ulcerations*. Dr. H. Kennedy (*Dublin Journ. Med. Sci.*, Jan. 1874) especially commends it in *chronic rheumatism*, and as an aid to cod-liver oil, etc., in *chronic phthisis*. It has also been employed to arrest the secretion of milk and to relieve *dysuria*. The various uses of conium as an alterative certainly have no definite physiological basis, but they appear to be justified to some extent by clinical experience.

ADMINISTRATION.—One of the great practical drawbacks to the use of this drug is the uncertainty of its preparations. The dose of the extract (*Extractum Conii*, U.S.) is one grain; of the tincture, fʒss to fʒi; of the fluid extract (*Extractum Conii Fluidum*), mʒj to mʒii: all of which must be administered in increasing doses until some effect is experienced. Of these preparations the last is certainly the best. The English *Stavus* (*Conii*) as praised by some writers, I have known to be used by the same without effect.

The variability of all the preparations has its origin—first, in the ~~ing~~ amount of the active principle in the drug; secondly, in the ~~ing~~ stability of this principle; and thirdly, in the proneness of the ~~ing~~ substance to spontaneous decomposition, even when kept under

the most favorable circumstances, and to a much greater extent when exposed to light and air. The alkaloid, on the whole, would probably be the best form in which to use the remedy; but it is not officinal: it has been used abroad to a considerable extent. Its unstable nature, however, is an obstacle to its use, and has caused M. Mourrut to propose its hydrobromate, which is said to be a crystalline stable salt (*Bull. Thérap.*, xc. 446, xci. 1). The dose of the alkaloid or of its salt is one-twentieth to one-twelfth of a grain, which may be dissolved in alcohol.

TOXICOLOGY.—Sufficient has been said about the symptoms caused by conine. After death from it no distinctive lesions are to be found, only the usual indications of death from asphyxia. The treatment consists in the immediate evacuation of the stomach and the exhibition of tannic acid,—the tannate formed is, however, probably more or less poisonous,—with the use of external heat and of internal stimulants; artificial respiration should be steadily maintained so long as there is the faintest indication of cardiac action. No physiological antidote is known; but it is possible that atropine might be of service by aiding to maintain the respiration.

FAMILY VII.—RESPIRATORY STIMULANTS AND DEPRESSANTS.

THE drugs which are chiefly used by the physician for the purposes of stimulating the respiratory centres are ammonia, caffeine, atropine, cocaine, and strychnine. For discussion of these drugs the reader is referred to the respective articles upon them. It is, perhaps, not supererogatory to point out that atropine, cocaine, and strychnine are the most certain in their respiratory action, affording the most satisfaction in the treatment of respiratory depression, and, further, that very frequently the best result is to be obtained by the consentaneous use of two of the stimulants (see page 286). In the face of a depressing poison, strychnine is probably the most certain and constant in its action, though its influence in health is scarcely so marked as that of cocaine, and perhaps even of atropine. In all cases of severe narcosis the alkaloidal salts should be used hypodermically.

Very rarely in practical medicine is a *respiratory depressant* indicated. The only condition is that of a cramp asphyxia, such as may occur in a strychnic or other tetanic convulsion, under which circumstances a centric motor depressant should be employed. It is true that certain drugs, such as aconite and veratrum viride, not placed among the motor depressants, are powerful respiratory depressants, but their action upon the circulation or other parts of the animal system not connected with respiration is so severe as to forbid their use, unless under very exceptional circumstances. When the peril is imminent in a cramp asphyxia, and there is enough movement of air in the chest, chloroform or nitrite of amyl should be used through the respiration. If this cannot be done, nitrite of amyl should be given hypodermically. When the symptoms are severe but not immediately urgent, and swallowing is possible, chloral is the best, quickly acting, remedy, but usually it should be supported by large doses of the bromide of potassium, which, if not powerful enough to be depended upon by itself, is by the persistency and constancy of its action very valuable as an *adjuvant*.*

* There is perhaps no complete justification for the recognition of classes of respiratory stimulants and depressants, since probably the respiratory centres share the action of drugs upon the whole motor tract of the spinal cord; so that any drug which is a motor depressant or a motor stimulant is correspondingly a respiratory depressant or a respiratory stimulant.

ASPIDOSPERMA. U.S.—QUEBRACHO.

The bark of an evergreen South American tree, *Aspidosperma Quebracho-blanco*, in which, according to Heine, there are five distinct alkaloids. Of these, probably the most important is *aspidospermine*, discovered by Fraude in 1878.*

Our knowledge of the physiological action of quebracho bark is very imperfect. According to Dr. F. Penzoldt (*Die Wirkungen Quebrachodrogen*, Erlangen, 1881), large doses of the drug cause in the lower animals motor paralysis, dyspnoea, and finally death from asphyxia. The breathing is said, even in moderate dose, to become slower in rate but deeper, and the blood-pressure not to be affected at all, or after toxic doses only late in the poisoning. It is affirmed that although death seems to take place from asphyxia, the venous blood always is more or less of the arterial hue; and Dr. Penzoldt believes that the relief of dyspnoea obtained clinically by the use of the drug is caused by its increasing the power of the red blood-disks to absorb oxygen, whilst the dyspnoea and fatal asphyxia of quebracho-poisoning are due to its so affecting the red blood-disks that they are unable to give up their oxygen to the tissues. This curious theory does not seem to me proved; the whole subject urgently needs restudy.

The present class at this time has been recognized, however, chiefly because, owing to the imperfection of our knowledge and the uncertainty in regard to the real physiological action of *aspidosperma*, it seemed otherwise impossible to place the drug.

* The other alkaloids are *aspidospermatine*, *aspidosamine*, *quebrachine*, *hypoquebrachine*, and *quebrachamine*. Their physiological action has been studied to some extent. Harnack and Hoffmann (*Zeit. für Klin. Med.*, 1884, vol. viii.) find that *aspidospermatine* causes in the frog respiratory paralysis, with palsy of all the striated muscular fibre of the body, including the heart-muscle. Upon mammals it acts very feebly, its most marked influence being upon the respiration. *Quebrachine* acted upon the frog precisely as did *aspidospermatine*. Its influence upon the mammal was at least twenty times as great as that of *aspidospermatine*, comparatively small doses producing death by respiratory paralysis. *Quebrachamine* acted very much as did *aspidospermatine* upon the breathing and upon the muscular fibre. *Aspidosamine* acted upon the breathing and upon the muscular fibre like *aspidospermatine*, but also paralyzed the motor nerve-endings. Its influence upon mammals was quite feeble. According to this research, the combined alkaloids have especial influence upon the respiration and the respiratory centres, and at the same time affect the muscular fibres directly and the peripheral nerve-endings. Schiffer (*Archiv. f. Physiol.*, 1883, p. 249) has found that the extract of a commercial quebracho blanco produces in the rabbit general muscular weakness, followed by paralysis with greatly diminished reflexes and an appearance of the deepest narcosis, with increased frequency of breathing, unaltered cardiac activity, and unchanged pupils. After very large doses death occurs in a very short time, preceded by convulsions. The motor nerve-trunks were found even during life almost devoid of functional activity. The exact nature of the bark used for the making of the extract is not stated. Eloy and Huchard (*Archives de Phys. et Path.*, April 1, 1886) found that the extract of quebracho blanco has some effect on sensibility after the taking out of the quebrachine, hypoquebrachine, *aspidospermine*, and *aspidospermatine*, but that these alkaloids themselves have no effect on general sensibility. The four alkaloids named produced paralysis, with, if in excessive doses, tonic convulsions, and all of them had the power of reducing the temperature, quebrachine being in this respect the most active. *Aspidospermine* increased the amplitude of the respiratory movements to a very marked degree, but in overdose produced irregularity and failure of respiration. The three other alkaloids had much less effect upon respiration.

There is, however, much clinical assertion that quebracho is a valuable stimulant, not only when the respiration is embarrassed by *emphysema*, *bronchitis*, *chronic pneumonia*, or other complaints mechanically influencing the lung function, but also in *asthmatic*, *uræmic*, and even *cardiac dyspnœa*.

Aspidospermine of commerce is a more or less impure mixture of all alkaloids of the bark, and hence may be considered to represent its activity. The dose of the commercial *aspidospermine* is from a quarter to half a grain (0.016 to 0.03 Gm.). The *fluid extract* (*Extractum Aspidospermatis Fluidum*, U.S.) may be given in doses of from a quarter to one fluidrachm (1 to 4 C.c.); the *solid extract* is said to be ten times the strength of the crude bark, and may be given in doses of from one to three grains (0.065 to 0.194 Gm.).

ORDER II.—CARDIANTS.

FAMILY I.—CARDIAC STIMULANTS.

THE term cardiac stimulants is here used to designate a number of medicines which, when given internally, increase the power and force of the circulation, and are used by the physician for such purposes. There are some substances which are heart-stimulants in reality, but which possess other properties in so great a degree as to overshadow their cardiac relations, and are not used by the physician to affect the circulation. Such medicines are considered in connection with those powers which give them their clinical value, and are consequently not included in the present class. Some of the members of this class are slow in their operation, some more rapid. Some produce increase in the pulse-rate, some lower it. It is evident, then, that no general indications can be laid down for their use, but that medicines so diverse must be studied individually.

AMMONIA.

Ammonia is a colorless, irrespirable, highly irritant gas, of a strong alkaline reaction, extremely soluble in water. It is obtained upon a large scale as a waste product in the manufacture of coal gas, and is officinal in watery and alcoholic solutions, and in various salts.

PHYSIOLOGICAL ACTION.—Locally applied, ammonia is a very powerful irritant. When inhaled, it causes intense irritation and finally inflammation of the mucous membrane of the air-passages, and its solution, if kept in contact with the skin, reddens, blisters, and at last produces even sloughing of the parts. When ammonia is injected into the veins of animals in considerable quantities, it causes violent convulsions, with remarkable disturbance of the respiration, followed, if the dose has been large enough, by death in a very short time. (F. Lango, *Archiv für Experiment. Path. und Pharm.*, Bd. ii. p. 368; V. Feltz et E. Ritter, *Journal de l'Anatomie et de la Physiol.*, 1874, p. 326; Funke, *Pflüger's Archiv*, Bd. ix. p. 426.) The respiration, if not interfered with by the tetanus, is enormously accelerated. Billroth (*Archiv für Klin. Chirurg.*, Bd. vi. p. 421) states that the temperature falls enormously in animals poisoned with ammonia.

Respiration.—When a small quantity of ammonia is injected into the blood of an animal, the breathing is greatly accelerated; after larger doses a period of arrest of respiration occurs in expiration (Funke), at once or in the course of a few seconds, and precedes the hurried breathing. In regard to the effect of section of the pneumogastrics upon the respiratory action of ammonia there is some disagreement: thus, in Funke's observations the primary arrest of respiration was always present, while in the experiments of Lange it was always absent. Both observers note, however, that section of the pneumogastrics does not interfere with the increased rapidity of the breathing, and Funke especially remarks that the change from the slow, deep breathing of divided vagi to the extremely rapid respiration of ammonia-poisoning is colossal. Professor Binz (*Centralb. f. Klin. Med.*, ix., 1888) finds that in chloralized rabbits ammonia increases very greatly not only the respiratory rate, but also the absolute amount of air breathed. Ammonia is evidently a powerful direct stimulant to the respiratory centres.

Circulation.—The main practical interest in the physiological action of ammonia centres in the circulation. It is chiefly as an arterial stimulant that it is used in medicine, and clinical experience assigns to it a powerful but fugacious action on the heart. The only experiments on the subject besides my own that I have met with are those of Lange. When the drug is injected into the veins of animals there is a momentary fall of the arterial pressure, followed by a sudden, decided rise, and a corresponding increase of the pulse-rate. These phenomena are independent of the convulsions, because in Lange's experiments they occurred in curarized animals. According to Lange's studies, the rise of pressure is not due to any stimulation of the vaso-motor centre, because it took place equally after division of the cord,—i.e., after the separation of the arterioles from the vaso-motor centre. The increased arterial tension which follows the exhibition of ammonia must therefore be due to an action either upon the heart itself, or upon the peripheral vaso-motor nerve-fibres, or upon the muscular fibres in the coats of the arteries. As in Lange's experiments the increase of the pulse-rate did not accompany the rise of pressure after section of the spinal cord, it would seem to be caused by a stimulant action upon the accelerators of the heart, which are of course paralyzed by spinal section. The fall of arterial pressure which immediately follows the injection of ammonia into the jugular vein is probably due to a direct action of the concentrated poison on the heart. Previous section of the vagi does not prevent it, and when the dose is sufficient it is rendered permanent by diastolic arrest of the heart's action. That it is not caused by spasm of the pulmonic arteries is shown by the fact that when death occurs the left heart is found full of blood. When administered in toxic doses, ammonia probably has some effect upon the peripheral arteries, for Feltz and Ritter found that the blood of a dog

killed by the poison not only did not contain anything like the normal amount of oxygen, but even when shaken up with the gas refused to absorb it; further, under the microscope the red disks were found to resist the action of acetic acid to a markedly abnormal degree.

Motor System.—The convulsions already spoken of as being produced by ammonia are not cerebral, since Lange found that they occur equally after division of the cord; nor are they peripheral, since in Funke's experiments tying of the artery of a limb failed to arrest them in that part, while section of the nerve was followed by immediate quiet: they must be spinal. Ammonia, in toxic doses, acts, therefore, as a stimulant to the motor function of the spinal cord, heightening, as has been proved experimentally by Funke, its reflex activity.

Elimination.—The volatility of ammonia and the extreme fugaciousness of its action would seem to indicate its elimination by the lungs; but Feltz and Ritter (*loc. cit.*, p. 323) failed to find it in the breath of a poisoned animal, and the researches of H. Bence Jones apparently demonstrate that at least a portion of it is oxidized in the system (*Philosophical Transactions*, London, 1851). The last observer found, to his surprise, that even large doses, far from increasing the alkalinity of the urine, seem at times to heighten its acidity. It occurred to him that the ammonia might be oxidized: and he accordingly found that the natural product of its oxidation, nitric acid, appears in the urine after the exhibition either of ammonia itself or of its tartrate, carbonate, or muriate. It is probable that some portion of the ammonia is, in conjunction with carbonic acid, converted into urea.*

Summary.—The officinal ammoniacal solutions are violent irritants and corrosives, when in overdose and concentrated form producing death very rapidly by their local action on the respiratory (laryngeal asphyxia) or alimentary tracts (gastric collapse). In moderate dose they are powerful stimulants to the respiratory centres and also to the circulation, increasing greatly the respiratory air-movements and also the arterial pressure, the latter increase being due to the stimulation of the heart and also of the vaso-motor system. Toxic doses, injected or absorbed into the blood-vessels, paralyze the respiratory centres and cause death by asphyxia, at the same time depressing the heart itself and also the vaso-motor system. Upon the motor side of the spinal cord small doses of ammonia act as a stimulant and large doses as a paralyzant. After its absorption ammonia undergoes rapid oxidation and is converted into nitric acid and water, with possibly other compounds. Owing to its violent locally irritant influence and to the fugaciousness of its systemic action, ammonia is of little value in the

* The relation of ammonia to the formation of urea is of such purely physiological interest, and its discussion would require so much space, that I dismiss it with the following references, which will give the reader a sufficient key to the literature: *Arch. f. Exper. Path. u. Pharm.*, li, viii., z. 125, xii. 77; *Zeitschr. f. Physiol. Chem.*, li. 29, iv. 36; *Zeitschr. f. Biol.*, xlv.

treatment of disease, but may be used in a crisis of cardiac failure or collapse. It is also employed in medicine as a stimulant antacid and as a counter-irritant.

THERAPEUTICS.—Externally, ammonia is much used as a constituent of irritating liniments, and, on account of its efficiency and cheapness, is very valuable. By inverting a watch-glass full of the stronger water of ammonia upon the skin, a blister may be raised in a very few minutes; but, as the effects of the application are apt to be severe, the use of it is justifiable only under rare circumstances.

Internally the chief indication for the use of ammonia is *failure of the heart's action*. The more sudden and purely functional this is, the more efficacious is the remedy, which should in such cases be not only administered by the stomach, but also inhaled through the nostrils, as the local action of the irritant vapor upon the mucous membrane has a very arousing influence. When the failure of the circulation depends upon a slow and persistent cause, as in *adynamic fevers*, ammonia is not generally useful, but may be employed as an adjuvant to alcohol in the crisis of the disorder.

In *poisoning by venomous serpents*, ammonia has been largely used, but certainly is in no sense antidotal, since, according to the experiments of Dr. Fayrer (*Indian Annals of Medical Science*, 1872), mixing it with the poison before injecting the latter into an animal does not in any way delay the fatal result. As an adjuvant to other more powerful stimulants, and especially to alcohol, ammonia may be useful in these cases. Dr. G. B. Halford, of Melbourne, Australia, has asserted (*Melbourne Argus*, 1872) that when injected into the veins its effects in poisoning from snake-bite are very extraordinary, and several cases of recovery after its use in this manner have been reported. It is far from certain, however, that these cases would have died had no medication been practised; and Dr. Fayrer states that in an extended series of experiments upon animals he has not found injection of ammonia to be of any use. Ammonia is not a specific in snake-poisoning; but, as the injection can do no harm, it may be practised.

In failure of the heart during *anæsthesia*,* and in poisoning other than from snake-bite, hypodermic injections of ammonia† have seemed in a number of reported cases to be of very great service. The same may be said of *sudden collapse* in disease, as sometimes is seen in the *exanthemata*, in *cholera*, and not rarely in *pernicious malarial fever*,‡ or after surgical operations or injuries. From fifteen to twenty-five minims

* Professor Ringer (*Practitioner*, xxvii.) finds that ammonia added to the frog's heart depressed with chloroform, iodoform, etc., has a pronounced effect in re-establishing its action.

† See *Indian Med. Gaz.*, June 1, 1872; *Med. Times and Gaz.*, Nov. 1872; *Chicago Med. Journ.*, 1872; *London Med. Record*, i., 1873; *L'Abeille Méd.*, Aug. 1874; *Berlin. Klin. Wochenschrift*, No. 24, 1874; *Archives Gén.*, ii., 1874; *Lancet*, 1879, ii. 158; *New York Med. Rec.*, xv. 532.

‡ See Dr. Zuelzer, *Revue de Thérap. Méd.-Chir.*, July 1, 1872.

of the aqua ammoniæ fortior, diluted with four times its bulk of water, should be thrown directly into a vein of the arm, and repeated in fifteen minutes if necessary.

Professor Stillé and other authorities claim for ammonia an antidotal influence in *alcoholic intoxication*; but that it can relieve absolute drunkenness is, I think, very doubtful. Ammonia appears to have a tendency to act upon the mucous membrane of the lungs, and may be used as a stimulant expectorant in adynamic pectoral inflammations, as in *typhoid pneumonia*. As a stimulant antacid, it is frequently of service in cases of *headache from gastric acidity*.

TOXICOLOGY.—When taken in large amounts, ammonia acts as a violent corrosive poison, producing generally abdominal pain, vomiting, bloody purging, and other symptoms of gastro-enteritis, with convulsions, collapse, and finally death. In some cases symptoms of impending suffocation, resulting in death from asphyxia, have occurred, and at the autopsy intense redness and congestion of the bronchial mucous membrane have been present, due no doubt to the irritant's having found its way into the bronchi. The intellect may be clear to the very moment of death, or stupor, and finally coma, may be developed. In the rare instances in which death has taken place within five minutes from the ingestion of the poison the fatal result has probably been brought about by œdema of the larynx. If the victim survive for a few hours recovery usually occurs, but the convalescence is commonly protracted, and permanent ill health may result from the destructive lesions produced by the poison. These lesions are to be found not only in the respiratory and gastro-intestinal tracts, but also in the kidneys (see case, *Boston Med. and Surg. Journ.*, cxxv., 1891). The treatment of poisoning by ammonia consists in the neutralization of the ammonia as soon as possible by vinegar or other dilute acid, and the meeting of indications as they arise. If the œdema of the glottis be threatening, tracheotomy should at once be performed.

ADMINISTRATION.—There are four official preparations of uncombined ammonia itself,—namely, *Aqua Ammoniæ Fortior* (*Stronger Water of Ammonia*), sp. gr. 0.901, *Aqua Ammoniæ* (*Water of Ammonia*), sp. gr. 0.960, *Spiritus Ammoniæ* (*Spirit of Ammonia*), and *Spiritus Ammoniæ Aromaticus*, or *Aromatic Spirit of Hartshorn*, as it is usually called.

To reduce the strength of the first of these preparations to that of the second requires the addition of one and a half measures of water. The spirit is of varying strength, but is somewhat weaker than the simple water. The aromatic spirit contains both ammonia and its carbonate. For hypodermic use the waters of ammonia are to be preferred. The spirits, especially the aromatic, are best suited for internal use. The dose of the simple spirit is from twenty-five drops to a teaspoonful, properly diluted.

Ammonium Carbonate, U.S. (*AMMONII CARBONAS*), is the best prepa-

ration for continuous use and in typhoid *pneumonia*. It occurs in white, translucent, fibrous masses, which on exposure become opaque and efflorescent, parting with ammonia and passing from a sesqui- into a bi-carbonate. It is soluble in four and a half times its weight of water, and may be given in solution in doses of from five to ten grains, repeated *pro re nata*. The effects of a single dose upon the system probably do not last over two hours.

Ammonium Nitrate (AMMONII NITRAS, U.S.) is official for the preparation of nitrous oxide; *Ammonium Chloride* (AMMONII CHLORIDUM, U.S.) will be considered under Expectorants; *Ammonium Iodide* (AMMONII IODIDUM, U.S.) under Alteratives.

ALCOHOL. U.S.

Alcohol Absolutum, U.S. (*Absolute Alcohol*), i.e., ethyl alcohol containing not more than one per cent. by weight of water, is a colorless, volatile liquid, boiling at 172° F., not congealed by a cold of -166° F., and having the specific gravity of 0.797. It is official, but is never used except for chemical purposes.

The U.S. Pharmacopœia recognizes ALCOHOL, containing 94 per cent. by volume of absolute alcohol, and having the specific gravity of 0.820; ALCOHOL DEODORATUM, *Deodorized Alcohol*, containing 95.1 per cent. by volume of alcohol, and having the specific gravity of 0.816; and ALCOHOL DILUTUM, *Diluted Alcohol*, containing 48.6 per cent. by volume of absolute ethyl alcohol, and having the specific gravity of 0.936.

Alcohol also exists in the official SPIRITUS FRUMENTI, or WHISKY, and SPIRITUS VINI GALlici, or BRANDY, which are obtained respectively by the distillation of fermented grain and of fermented grapes, and should contain from forty-eight to fifty-six per cent. of absolute alcohol, and in the official VINUM RUBRUM, or *Red Wine*, and VINUM ALBUM, or *White Wine*. For medicinal use, brandy should be at least four and whisky at least two years old.

Alcohol is formed out of sugar by fermentation; but, as a discussion of the natural history and chemistry of this process, to be of value, would occupy much space, the reader is referred for it to works especially devoted to chemistry and to materia medica.

PHYSIOLOGICAL ACTION.—The phenomena which follow the ingestion of alcohol are, unfortunately, so well known as to make any description of them here unnecessary, and I shall at once proceed to the discussion of the action of the drug upon different portions of the organism.

Nervous System.—I have not met with a close experimental study of the order in which the nervous centres are affected, but it is scarcely doubtful that alcohol acts upon them as does ether, except that the latter substance, being much more volatile than alcohol, is consequently absorbed and eliminated much more rapidly, so that its influence is more evanescent. I know by experiment that the vapor of alcohol is

capable of producing the stupor known as anæsthesia, and, further, that this anæsthesia may be deepened into death, accompanied by all the phenomena of fatal ether-narcosis. It is probable that there is an early stage in the action of alcohol in which not only the cerebral but it may be even the spinal centres are stimulated, but certainly in the advanced stages of alcohol-poisoning muscular relaxation and the loss of reflex activity are altogether or in part due to the sedative influence upon the motor cord. The theory of a primary stimulation gains plausibility from the experiments of Mommsen (*Arch. f. Patholog. Anat.*, lxxxiii. 243), in which it was found that the excitability of the peripheral motor nerve is primarily increased by the local action of alcohol. According to Dogiel (*loc. cit.*), in the alcoholized dog both sensory and motor nerves are markedly depressed.

Circulation.—When alcohol is given to healthy men, it increases the frequency, and I believe also the force, of the pulse; although the sphygmographic tracings of Parkes and Wollowicz, whilst indicating an increased rapidity of the ventricular contractions, with shortening of the diastole, do not give distinct indications of increased arterial pressure. The experiments made upon the lower animals have yielded results which at first sight appear somewhat contradictory. When, however, the different effects of different doses of alcohol are clearly distinguished, most of the apparent contradictions disappear. Thus the results obtained by Dr. H. Zimmerberg, who found that alcohol reduces both the rate and force of the pulse, evidently depended upon his employing toxic doses of alcohol. The same objection holds with the experiments of Z. Gutnikow (*Zeitsch. f. Klin. Med.*, xxi., 1892), in which were given to dogs doses of two hundred and fifty* grammes of from fifty to seventy per cent. alcohol, with a marked fall both in the arterial and in the venous pressure. There was also in Gutnikow's observations a fall in the intra-cardiac pressure, both auricular and ventricular. In some cases the intra-cardiac fall preceded the fall of the arterial pressure. In the experiments of J. Dogiel, and similarly in those of Dr. J. D. Castillo (*Phil. Med. Times*, xi. 45), small doses of alcohol produced marked increase of the arterial pressure, an increase which was followed, when the dose was large enough, by a fall of the arterial pressure. This result is in general accord with that obtained by Dr. S. Potts Eagleton† (*Univ. Med. Mag.*, Sept. 1890), and I think must be considered as representing the ordinary action of the drug.

In the experiments of Castillo, and also of those of Eagleton, the rise of pressure occurred after previous division of the pneumogastric,

* The weight of the dogs is not given, and the amount per kilo, therefore, cannot be estimated.

† Eagleton's experiments were made with a continuous injection of alcohol, and in two of them the results were somewhat different from those ordinarily obtained. The reason of this is not obvious. None of his dogs appear to have been curarised, and the peculiar method of experimentation requires the results to be interpreted with great care.

accelerators, and spinal cord, and would, therefore, seem to be due to a direct action upon the heart itself, a conclusion corroborated by the effects of alcohol upon the isolated heart of the frog, as determined by Castillo. It would seem, therefore, that alcohol must be considered to be a *direct stimulant to the heart*.* The fall of the arterial pressure occurs after section of the cord, and must, therefore, at least in part, be due to direct action upon the heart itself or muscle fibres in the vessel walls, a conclusion which is in conformity with the experiments of Castillo, in which stimulation of a sensitive nerve caused rise of pressure, proving that the vaso-motor system was still capable of responding to stimuli. Certainly the known action of alcohol upon the excised frog's heart, and the diastolic arrest produced by it in the mammal, prove that *in overdose alcohol is a direct depressant to the heart*; nevertheless, there can be little doubt but that it exerts a similar *depressing influence upon the muscle fibres in the walls of the vessels*; indeed, there is much reason for believing that at a time at which the heart is still under alcoholic stimulation the blood-paths are widened out, for Dr. John C. Hemmeter (*New York Med. Rec.*, xl, 1891) has found in experiments made with Ludwig's stromuhr that alcohol may increase the velocity of the blood-current. Unfortunately, Dr. Hemmeter does not give the amount per kilo of alcohol used in his experiments, and does not seem to have experimented with varying doses.†

* In opposition to the general experimental and clinical evidence are the results obtained by Professor Martin (*Maryland Med. Journ.*, x, 292) in experiments made upon the dog's heart, isolated by a long and complicated procedure invented by himself.—experiments which have been repeated with similar results by J. C. Hemmeter (*Johns Hopkins Univ. Stud. Biolog. Labor.*, iv.). Professor Martin found that blood containing one-eighth per cent. by volume of absolute alcohol has no immediate action upon the isolated heart, that blood containing one-fourth per cent. diminishes within a minute the work done by the heart; and that blood containing one-half per cent. always diminishes remarkably the heart-work, and sometimes nearly destroys it, so that not enough blood is pumped out of the left ventricle to supply the coronary artery. The curious observation was made that cutting away the pericardium stopped the action of even one-half per cent. of alcohol. The explanation of this, offered by Professor Martin, is that the alcohol so relaxes the cardiac muscle that there is not room in the pericardium for a full diastole, the relaxed heart being, even in its systole, about sufficiently large to fill the pericardium. This explanation is hardly satisfactory. Can there be a local inhibitory cardiac apparatus, with peripheral filaments in the pericardium which are irritated by alcohol, and whose removal prevents the action of the alcohol?

It seems to me at present not possible to satisfactorily examine the results obtained by Professor Martin. Mr. Hemmeter suggests that they may be due to alteration produced by the alcohol in the defibrinated blood, but to my mind this hardly suffices. Certainly the operative procedures are attended by so much shock as to seriously affect, and probably paralyze, the cardiac nerve-centres. Whatever the explanation may be, it is evident that the action of alcohol upon the isolated heart is very different from what it is in the normal dog or man, and Hemmeter has shown that, during these experiments, under the influence of the alcohol, regurgitant murmurs are developed and hemorrhages occur into the cardiac tissue.

The velocity of the blood-current in the arterial system depends upon the relations between the propulsive force and the resistance: the greater the propulsive force the greater the velocity, and the greater the resistance the less the velocity. It will be seen at once that the force and velocity are not synonymous or necessarily accordant. If, for instance,

Dogiel, in his experiments, found that the pulse-rate is first increased and then diminished and then increased, under the action of alcohol. Both Castillo and Eagleton have noticed also primary increase in the rate of the cardiac pulsations, an increase which Dogiel attributes to stimulation of the accelerator nerve, but which Castillo has found occurs in the mammal when the heart has been isolated after section of the cord, and which Eagleton has noted in the excised frog's heart. Alcohol in moderate dose, therefore, acts as a *direct stimulant* to the rate as well as to the force of the heart's beat. Large doses have been noted by various observers to lessen pulse-rate in the animal, but certainly in the human system, slowing of the pulse is not a distinct phenomena of alcohol-poisoning.

There seems to be little reason for supposing that alcohol in therapeutic dose has an appreciable effect upon the blood, but as long ago as 1841, C. H. Schulz (*Hufeland's Journ.*, April, 1841) observed that mixed with the blood outside of the body it not only caused coagulation, but also separation of the hæmoglobin from the corpuscles. It is probable that to the action of the alcohol upon the hæmoglobin is due the fact noted by Schmiedeberg (*Virchow's Archiv*, vol. li. p. 171) that alcohol mixed with blood lessens its ability to yield oxygen in the presence of a reducing agent. Jaillet and Hayem (*Virchow and Hirsch, Jahrbucher*, 1884) state that in rapid alcoholic poisoning in animals, extensive alteration in the blood corpuscles can be discovered, many of these bodies being shrivelled and altered in form, with yellow precipitates of hæmoglobin in their interior.

Temperature.—Owing no doubt to the sensations of warmth induced by its local action on the stomach and by the increased activity of the circulation in the extremities, alcohol has been looked upon as a promoter of animal heat. As long ago as 1848, however, Duméril and Demarquay asserted that after the administration of large doses there is a fall of temperature. Of late years much attention has been given to the subject, and positive results have been reached. As almost all experimenters are in accord, it does not seem worth while to occupy space

a drug increases the resistance without affecting the propulsive force, the blood-pressure may be raised or remain almost unchanged while the velocity will decrease. Dr. Hemmeter gives the following as possible variations to which the main factors in the making of velocity and arterial pressure are subject:

1. The energy of the heart contractions remains the same and the resistance (a) increases, then blood-pressure increases and velocity decreases. (b) Resistance decreases, then blood-pressure decreases and the velocity increases.
2. The energy of the heart activity increases and the (a) resistances are the same, then the blood-pressure and velocity increase. (b) The resistances increase, then blood-pressure increases and velocity remains the same. (c) The resistances diminish, then blood-pressure remains the same and velocity increases.
3. The energy of the heart activity decreases and at the same time (a) the resistances are the same, then the blood-pressure and velocity are reduced. (b) The resistances are correspondingly greater, then blood-pressure remains the same and velocity decreases. (c) The resistances are correspondingly smaller, then blood-pressure sinks and velocity is the same.

with a discussion of the history of the subject. References are given to the principal original memoirs.*

It is certainly demonstrated that lethal doses of alcohol produce in animals a fall of temperature which often amounts to 5° C., and that even when intoxication or alcoholic narcosis is alone induced the depression of temperature may amount to 3° C. The proportionate dose necessary to produce distinct nervous symptoms is enormous in the lower animals as compared with man; yet, after the ingestion of amounts of alcohol which are not enough to cause intoxication in the animal, the fall of temperature is slight,—rarely more than 1° C., and according to Ruge (*loc. cit.*, p. 265) usually from $\frac{1}{4}^{\circ}$ to $\frac{1}{2}^{\circ}$ C.

The experiments of Richardson show that in some cases very minute doses of alcohol increase slightly the temperature ($\frac{1}{4}^{\circ}$ F. in mammals, 1° F. in birds). As regards animal heat, alcohol acts upon man as upon the lower animals. After doses only sufficient to increase the activity of the circulation, probably as a result of this increase, there is sometimes a very trifling exaltation of temperature (Parkes and Wollowicz). After larger doses there is a slight fall of temperature, and when full intoxication is induced this fall may amount to 3° F. (Ringer and Rickards.)

Upon animals suffering from pyæmic fever Bouvier and subsequent observers have found that alcohol exerts a decided antipyretic action, very large doses of it lowering the temperature as much as $8\frac{1}{2}^{\circ}$ C., and altogether preventing the occurrence of fever if narcosis be produced before the development of the latter. In fever in man alcohol exerts a similar influence, but in order to make its antipyretic action decidedly manifest, doses so large as to be toxic must be given (Ringer and Rickards). It has been noted both in man and in the lower animals (Bouvier) that when the individual is accustomed to the free habitual use of alcohol the temperature is scarcely affected even by large doses.

Dr. Franz Riegel, of Germany (*Deutsches Archiv f. Klin. Med.*, 1873), made a very elaborate investigation upon the action of alcohol upon the temperature in man, performing as many as eighty-six experiments. The conclusions which he arrived at are in exact accord with those reached by most students of human physiology as well as by most experimenters upon the lower animals. As his conclusions embody the whole subject in a single paragraph, and may be received as absolutely demonstrative, I give them *in extenso*.

"1. Alcohol, even in moderate doses, in many cases causes a lowering of the temperature of the body. The amount of this diminution averages, as a rule, only some tenths of one degree. 2. Only exceptionally is there noticed an elevation of the temperature consequent upon the administration of alcohol; not unfrequently, at least after minute doses, there is no noticeable change. 3. The diminution of temperature in convalescents is, as a rule, less than in healthy subjects, or it may be altogether wanting. 4. In those who habitually drink alcoholic stimulants, the depressing influence of alcohol upon the temperature is almost always wanting. 5. The frequent repetition of the doses of alcohol diminishes their lowering effect upon the temperature. 6. The amount of diminution of temperature is directly proportional to the dose of alcohol given. 7. The depression of temperature caused by alcohol is for the most part of but short duration, and the temperature soon returns to its previous grade."

In severe acute alcoholism there is usually pronounced fall of temperature, precisely as in chloral and some other narcotic poisonings. This fall is undoubtedly largely due to excessive loss of heat, but the relations of alcohol to thermogenesis form such an integrant portion of its action on nutrition that its discussion will be postponed to the next heading.

Relations of Alcohol to Nutrition.—In studying the relations of alcohol or other drugs to the general bodily nutrition, the subject naturally divides itself into two parts, the first relating to the nutrition which has to do with the production of animal heat and of affording force for the needs of the system; the second, that which has to do with the building up of tissue and the chemical movements of protoplasm. The action of a drug upon heat production in the body can be directly studied by means of proper calorimeters, or it can be studied indirectly by chemical examination of the amount of oxygen consumed and of carbonic acid produced in the organism.

The first calorimetrical studies upon alcohol were those by Dr. Bevan Lewis (*Journ. Ment. Sci.*, vol. xxvi.). He found that in the rabbit alcohol sometimes produces a primary lessening of heat-production, most marked and pronounced after small doses, followed by a marked increase in heat-production, most pronounced after large doses of alcohol. In five observations by Professor Reichert and myself upon dogs, the average results were in accord with those by Dr. Bevan Lewis, although our individual

experiments yielded somewhat varying results. In some of these experiments heat-dissipation more than kept pace with the increase of heat-production, and the bodily temperature fell. In other instances the bodily temperature rose, showing that heat-production was increased more than heat-dissipation. When the seventh edition of this book was published, there seemed to be some evidence for the theory that alcohol increases heat-production, but the conclusion I reached was, "before it can be shown exactly how alcohol affects thermogenesis, further experiments are needed." Further experimentation has been provided by Professor E. T. Reichert (*Therap. Gaz.*, 1890). In eighteen experiments, he obtained increased heat-production in five and decreased heat-production in thirteen; the difference not depending upon dose, and the range of variation of result being as much as sixty-five per cent. For a complete discussion of the matter, the reader is referred to the paper of Professor Reichert; but certainly the discordant results obtained appear to prove that the action of alcohol upon thermogenesis is complex and varying, and that, therefore, it is probably in great part an indirect one. The alterations of heat-production are probably in large part secondary upon disturbances of heat-dissipation, the more recent researches confirming the conclusion which I had previously reached,— "that the great fall of bodily temperature which occurs after toxic doses of the drug is due to excessive heat-dissipation, which in turn is the result of vaso-motor paralysis." A further corollary is that our present evidence, derived from calorimetrical studies, indicates that alcohol does not pronouncedly and directly affect those nutritive processes through which the animal heat is maintained.

The effect of alcohol upon the elimination of carbonic acid by the lungs has been investigated by several observers, with different results. According to the researches of Böcker (*Beiträge zur Heilkunde insbesondere zur Krankheitsgenussmittel und Arzneiwirkungs Lehre*, abstracted by Claude Bernard in *Journal de Pharmacie*, tom. xv., 3d series, 1849), of N. S. Davis (*Transactions of the American Medical Association*, 1855), of Hammond (*Physiological Memoirs*, Philadelphia, 1863), of M. Perrin (*Archives Générales*, 6th series, tome iv.), of Boeck and Bauer (*Zeitschr. f. Biologie*, 1874, x.), and of Rumpf (*Pflüger's Archiv*, 1884, xxxiii.), there is a lessening in the amount of carbonic acid gas exhaled; on the other hand, Dr. E. Smith (*Brit. Med. Journ.*, 1859) found that small doses of alcohol increased the elimination of the gas, although brandy, whisky, and gin always lessened the production. Henrique (*Bull. Acad. Roy. de Belge*, v. 1883) found in himself that the consumption of oxygen was increased by alcohol. Wolfers (*Pflüger's Archiv*, 1882, xxxli.) noted in the rabbit an increase both of the oxygen ingestion and of the carbonic acid elimination.

In more recent studies, Bodländer (*Zeitschrift f. Klin. Med.*, xi., 1896) found that in rabbits and dogs alcohol produced a decrease of the oxygen consumption and carbonic acid production, whilst in man Zuntz

(*Fortschritte der Med.*, i., 1887) obtained an increase in carbonic acid production, and Geppert (*Archiv f. Exper. Path. und Pharm.*, xxii.) no important effect. In the older researches of Boeck and Bauer (*Zeitsch. f. Biolog.*, x., 1870) the result was arrived at that whilst small doses of alcohol diminish oxygen consumption, large doses increase it, and it is possible that the different results which have been obtained by investigators, as just quoted, may depend somewhat on the doses used by them. Nevertheless, the divergency seems at present not capable of being cleared up by such a supposition. If alcohol really did have a direct powerful influence upon oxidation in the general system the conclusions of investigators should be more in accord, and it would seem, therefore, probable that any influence which the drug may have is indirect, or is so feeble as to be set aside by various accidents, circumstances, or happenings; possibly even by other actions of the alcohol itself. This conclusion is in accord with that which has been reached calorimetrically, and the best expression of the present state of our knowledge is that it is not probable that alcohol has any pronounced positive influence upon the processes of oxidation or of heat-production in the system.

The determination of the action of the drug upon the chemical movements of protoplasm, and the destruction of albuminous materials in the body, is of course to be made by a study of its effect on the nitrogenous elimination. Among the earliest students, Böcker is commonly believed to have experimentally determined that it lessens the excretion of urea. I have seen only an abstract of the original paper. In it this is not positively asserted, but seems to be inferred. Dr. Hammond has performed a very elaborate series of experiments upon himself: first, when just sufficient food was taken to maintain the weight of the body; secondly, when more than enough for that purpose was ingested; thirdly, when not enough was taken. Under all these circumstances, urea, chlorine, and phosphoric acid were lessened in amount by the ingestion of alcohol. Parkes and Wollowicz (*loc. cit.*) affirm that their experiments gave a contrary result. In examining the reports of their experiments I find, however, that on one of the days the man taking the alcohol had a chill followed by fever. If this day be omitted, the average daily excretion of urea during the alcoholic period was 34.35 grammes; during the time when brandy was taken, 34.8 grammes; and during the water period, 35.02 grammes. The ingestion of alcohol seems, therefore, to have reduced the elimination of urea by about ten grains a day. Recently very careful experiments have been made by L. L. Riess (*Hoffmann und Schwalbe's Jahreshb.*, 1881, 357) upon two persons, but without analysis of food or feces. The exhibition of alcohol was followed by great lessening of the excretion of urea, and, to a less pronounced degree, of uric acid, chlorides, phosphates, and sulphates, and at the same time an increase of the bodily weight. H. Keller (*Zeits. f. Physiol. Chem.*, xiii., 1889) made

experiments upon himself. The prodromic period was three days; alcohol, one day; after-period, three days. The result was a fall of 1.4 grammes in nitrogen elimination during the alcohol day, with an increase in the after-period of one gramme above the norm. No examination of the faeces was made.

It is very properly objected to all the experiments which I have thus far quoted that no note was taken of other nitrogenous elimination than that through the kidneys. In 1878 (*Verhandl. d. Physiol. Gesellsch.*, Jan. 1879), Munk experimented upon dogs with great care to obtain nitrogenous equilibrium, using alcohol in both small and large doses and analyzing both urine and faeces. The result arrived at was that small doses of alcohol (less than 1.5 C.c. absolute alcohol per kilo) diminished slightly the nitrogenous output, whilst larger doses (over 2 C.c.) increased the elimination. The chief objection to Munk's experiments seems to be the short time in which alcohol was used,—three to five days.

In experiments made upon dogs by Charles Norris, Jr., and E. E. Smith, in Professor Chittenden's laboratory in Yale University (*Journ. Physiol.*, vol. xii., 1891), the alcohol period was from eight to ten days. The results were: in experiment No. 1, 1.9 C.c. alcohol per kilo being given, the nitrogenous output was increased two per cent.; experiment No. 2, 2.3 C.c. per kilo, decrease in nitrogenous elimination somewhat less than two per cent.; experiment No. 3, 2.7 C.c. per kilo being given, decrease about nine per cent. Woiske and Flechsigs are stated, in the memoir just spoken of, to have found in an experiment lasting thirty-two days that in a sheep sixty grammes daily of alcohol produced no distinct effect on the daily output of nitrogenous material, there being, in fact, an increase under the influence of alcohol of 0.5 gramme.

The results which I have thus epitomized are so varying, and the changes in the nitrogenous elimination noted so slow and inconsistent, that the accounting for differences by the theory of difference of dose is not plausible; and it seems to me that the conclusion of Professor Chittenden is correct, that so far as our present knowledge goes it does not seem probable that alcohol has a direct specific influence upon nitrogenous elimination,—that is, upon the chemical movements of protoplasm,—a conclusion which it should be remembered is corroborated by the experiments of Stammreich and Miura (see page 373).

A substance may very well have no specific relation with tissue changes and yet be capable of acting as a food which shall supply force to the animal organism. From the time of Liebig's celebrated classification of food until the appearance of the memoir of MM. Lallemand, Duroy, and Perrin, ingested alcohol was almost universally believed to be burnt up in the body. These latter observers asserted, however, that alcohol escapes unchanged from the body, not only because they were unable to detect in the blood or tissues any of the results of its oxidation,

such as aldehyde or acetic acid, but also because they found it unchanged in the expired air, the sweat, and especially in the urine. The results obtained by the French investigators were, however, seriously questioned by E. Baudot (*L'Union Médicale*, 1863), who demonstrated that the chromic acid test which Duroy and Perrin had relied on for detecting alcohol in the excretions is so delicate as to reveal .165 grain of alcohol in a quart of water; and Baudot further affirmed as the result of twenty experiments that, except after immense doses, the amount of alcohol eliminated by the kidneys is so small as practically to amount to nothing. In 1866 Dr. Schulinus (*Archiv der Heilkunde*, 1866), by a very elaborate and laborious investigation, confirmed the results of Baudot, showing that alcohol taken into the blood finds its way by exosmose into all organs in similar proportion, and does not escape through the kidneys unless in very trifling amounts. In several experiments he found that one-fourth of the ingested alcohol had disappeared from the body after from two to three and one-fourth hours, and, as but a fractional portion of the lost amount was eliminated, he concluded that it must have been burnt up. Adolph Lieben (*Annalen der Chemie und Pharmacie*, 1870, vii., Supplement. Bd. p. 236) has in a number of experiments arrived at results similar to those of Schulinus.

In 1865 a number of experiments yielded to Anstie, of London (*Stimulants and Narcotics*, (reprint) Philadelphia, 1868), similar results, and also demonstrated that the elimination from the lungs is exceedingly trifling. Thudichum investigated the matter on a large scale in 1864, and again with the assistance of Dupré in 1866 (*Tenth Report of the Medical Officer of the Privy Council*, London, 1868). In order to avoid the fallacies of the chromic acid test, the alcohol was obtained from the urine by repeated distillations. In the first instance forty-four bottles of wine, containing four thousand grammes of alcohol, were drunk by thirty-three men, out of whose urine, collected during the next six hours, ten grammes, or only 0.25 per cent., of the ingested alcohol were recovered. In the experiments of 1866 the process was substantially the same, but, greater care being taken to get absolute accuracy and to avoid loss during distillation, 0.82 per cent. of the amount administered was found in the urine. Professor Subbotin (*Zeitschrift für Biol.*, vii., 1871; *Schmidt's Jahrb.*, 1872, Bd. cliv. p. 261) has made an apparently close experimental study of the subject upon six rabbits, and has shown that elimination continues for a longer time than had been generally believed, and that twice as much of the alcohol escapes by the skin and lungs as by the kidneys. In one experiment he found that sixteen per cent. of the alcohol escaped unchanged in the first twenty-four hours; elimination after this time, although perceptible, amounted to very little. As he, like Lallemand and his colleagues, experimented with poisonous doses, his results confirm rather than contradict those of Baudot, Schulinus, Anstie, Thudi-

chum, and Dupré; for it is manifestly evident that after such doses elimination would be proportionately greater than after smaller quantities, as there naturally must be a limit to the powers of the system to oxidize alcohol. Professor R. D. Edes, in his experiments (*Boston Med. and Surg. Journ.*, 1872, p. 347), found that after small doses the amount of elimination by the breath is greater than that by the kidneys, although the contrary holds where large amounts have been administered; in either case the total amount eliminated was but a small percentage of the amount ingested.* Finally, Anstie (*Practitioner*, July, 1874) has repeated his experiments, using the method of Subbotin, and even subjecting a dog, which had been taking for some days very much larger amounts of alcohol than he had eliminated by skin, kidneys, rectum, and lungs, to distillation, with the results of confirming his first experiments and of finding no "residual alcohol"—i.e., alcohol left in the body—worthy of mention. In an elaborate research, Dr. Guido Bodländer found that he himself, after the use of alcohol in various quantities, eliminated by the kidneys about 1.2 per cent., and by the lungs about 1.6 per cent.; while in dogs he recovered from the breath about 2 per cent., from the urine 1.6 per cent., from the skin 0.14 per cent. of the ingested alcohol. He failed entirely to find alcohol in the intestinal excretions, and also, contrary to Lewald's observation in 1857, in the milk of a goat to which nearly a quart of brandy had been given (*Archiv f. Physiol.*, xxiii.). F. Strassman (*Archiv f. Physiol.*, xlix.) found 5.21 per cent. eliminated by the breath, 7.89 per cent. by the kidneys, leaving 87 per cent. as the amount destroyed in the organism.

These concurrent investigations† certainly demonstrate that but a small proportion of ingested alcohol is either eliminated from or accumulated in the body, and consequently that it must be oxidized in the body. It has been objected to this that no one has as yet been able to detect‡ in the blood any of the ordinary products of its oxidation; the probable reason of this is, however, that the oxidation is carried as it were at one bound to its ultimate end, the production of water and of carbonic acid. A strong corroborative proof that alcohol is largely consumed in the body is furnished even by the experiments of Lallemand, Duroy, and Perrin themselves, for they proved that elimination ceased, or at least could not be detected by the most delicate tests, before the alcohol had all escaped from the body.

* Professor Edes relied upon the chromic acid test, which Binz asserts to be fallacious. In the experiments made by Stenbach and Schmidt, under Professor Binz's direction, alcohol could not be detected in the breath, and Professor Binz believes that no elimination of it occurs from the lungs. He declares that the odor of the breath after drinking is not that of alcohol, but of the ethers and other volatile principles of the various liquids imbibed.

† I believe these results have also been confirmed by Wöhler, *Journal des Progrès*, xl., but I have not seen the original paper or any abstract of it.

‡ Duchek (*Vierteljahr. f. Prakt. Heilk.*, Bd. ii., 1853) did not, as he thought, demonstrate the presence of aldehyde in the blood of animals poisoned with alcohol.

A further strong confirmation of the theory that asserts the oxidation of alcohol in the body is found in the researches of our countryman Dr. H. Ford, whose experiments have, however, not been repeated, and therefore, although apparently carefully performed, lack the absolute authority of complete confirmation. Dr. Ford (*N. Y. Med. Journ.*, Jan. 1872) has worked upon the supposition that the hepatic sugar must be converted into alcohol in the body before its final destruction, and, using large quantities of blood of animals, has sought by repeated distillations to obtain alcohol from it.*

Pushing his researches still further, Dr. Ford used various tissues as the substances to be distilled. He also made elaborate calculations, based on the carbon ingested and on the carbon exhaled, as to the amount of alcohol which ought to be found in the capillary blood of the lungs. The results are expressed in the following table:

Alcohol in the capillary blood of the lungs:

	{ calculation based on carbon ingested	0.5403
	{ " " " carbon exhaled	0.5794
"	putrescent lung-tissue (mean of exp. 8, 9, and 11)	0.3819
"	fresh " " (" " 12, 13, and 14)	0.3076
"	putrescent thoracic blood (mean of exp. 1, 2, 3, 4, and 5)	0.7625
"	fresh " " (mean of table)	0.0841
"	putrescent liver-tissue (exp. 6)	4.3138
"	fresh " (mean of exp. 25, 26, and 27)	0.0190

The important facts seemingly established in the above table are; the correspondence between the amount of alcohol in the thoracic blood as obtained by calculation and by experiment; that the smallest quantity of alcohol is to be obtained from fresh liver-tissue, and the

* Space is wanting to describe in detail the very elaborate methods employed by Dr. Ford. The tests which he relied on, to prove that the liquid obtained was alcohol, were the chromic acid test, the peculiar inflammability, and the optical appearance of the alcohol in the conducting-tubes at the time the distillate commenced to boil. In order to prevent any possible oxidation of the alcohol during the process, Dr. Ford sometimes added sulphuretted hydrogen. The results of ten experiments are shown in the following table:

No.	Weight of Blood.	Interval from Death to 212°.	Temperature when Distilled.	Weight of First Distillation.	Weight of Final Distillate.	Weight of Alcohol obtained.	Weight of Alcohol for 10,000 parts of Blood.	With or without H ₂ S.
15	6970	60 m.	0.0659	0.0932	without.
16	9734	56	101°	1602	0.8416	0.0198	0.0263	without.

greatest from putrescent liver-tissue, in which the glycogen must have undergone fermentation. The fresh thoracic blood was blood which had not traversed the lungs; the putrescent thoracic blood of course represented the same blood with all its sugar fermented.

These researches of Dr. Ford are certainly corroborated by the discovery, first made, I believe, by A. Lieben (*Annalen d. Chem. Pharm.*, 1870), although usually attributed to Dupré (*The Doctor*, Feb. 1, 1873), that a substance exactly resembling alcohol exists in very minute quantity in the urine even of teetotalers.* M. Béchamp (*Lancet*, 1873), apparently without a knowledge of the work of the other chemists, obtained, from the urine of persons who had not taken any alcoholic beverage for a long time, alcohol in sufficient quantity to burn it. As Lieben also found that this substance exists in the urine of dogs, horses, and lions, and as A. Rajewski obtained it from healthy rabbits (*Archiv für Physiologie*, xi. 122, 1875), it must be acknowledged that our present knowledge strongly indicates that alcohol is formed and exists in the normal organism.

If alcohol be oxidized in the body, it must of course generate force, measurable by the modern standard of the heat-unit. A little calculation will show the importance, or rather the great amount, of the generated force. According to Dupré (*Practitioner*, 1872, vol. ix. p. 33), one gramme of alcohol oxidized in the body evolves 7184 units of heat, while the same weight of lean beef gives off only 1482 units of heat. It has been estimated that 9.3 ounces of lean beef—equal to about two ounces of alcohol—will supply the necessary force to maintain the circulation and respiration of an average man for one day. That is, four ounces of strong spirit will suffice for this purpose.

These considerations warrant the statement that in a certain sense alcohol is a food,—i.e., that it is capable of being used for the purposes of the organism. The question how far it is capable of replacing fats and hydrocarbons is not at this time capable of positive answer. The only researches which we have throwing light upon it are those which have been carried out after the plan originated by Professor von Noorden. According to this method the individual is brought into a condition of nitrogenous equilibrium by careful feeding, and when this condition has been thoroughly established, non-nitrogenous articles of food are withdrawn and alcohol substituted in isodynamic quantity. Under such circumstances, if the alcohol be superior to the hydrocarbon in replacing the nitrogenous material, less nitrogen should be eliminated than before its administration; if the power of the alcohol be less than that of the hydrocarbon, more nitrogen would be thrown off; if the

* It is asserted that the substance "is not alcohol. It passes over among the earliest products of distillation, yields acetic acid on being oxidized, reduces the bichromate of potassium when dilute sulphuric acid is present, and its aqueous solution has a lower density than water. It furnishes iodoform, and exists in the urine in a very small quantity." Possessing the physical and chemical characters of alcohol, to ordinary minds it is alcohol.

alcohol just replaced the hydrocarbon, the nitrogenous equilibrium would not be disturbed.

Dr. Stammreich's (*Berlin. Klin. Wochens.*, xxviii., 1891) experiments upon himself were two in number. In the first experiment there was a distinct lessening of the elimination of nitrogen during the alcohol period, showing that the alcohol replaced the nitrogenous material more actively than the corresponding fat mass for which it had been substituted. In the second experiment, with a lessened amount of nitrogen in the food, there was at first no pronounced change in the nitrogenous elimination, followed, however, after two days by a marked increase, which continued for three days after the withdrawal of the alcohol. A third set of experiments were made with very little nitrogen in the food. Under these circumstances there was a great increase of the elimination of nitrogen during the alcohol period.

As the result of the comparison of these various experiments Von Noorden reached the conclusion that when the food is rich in albuminous compounds, alcohol is able to replace hydrocarbon or fats; but when the food is poor in albumen it cannot do so. A similar series of experiments have been made by Dr. K. Miura (*Zeit. f. Klin. Med.*, xx, 1892), with results which are concordant so far as those experiments are concerned in which food with but little nitrogen is given. On the other hand, in opposition to Stammreich, Miura found that when the food is rich in albuminous material, alcohol is not able to replace the non-nitrogenous foods. Miura believes that these differences depend in part upon the facts that in Stammreich's experiments the alcohol was substituted for fats, whilst in his experiments it replaced hydrocarbons, which, according to Voit, have greater power of sparing the nitrogen materials than have the fats; so that alcohol might be equivalent to fats and yet not to hydrocarbons. How this may be must at present be left for the determination of future chemists.

All the enormous amount of labor whose results have been epitomized in the last few pages has not led to distinct positive conclusions which can be considered established beyond all peradventure; but certainly enough has been done to show that when the narcotic and stimulating influences of alcohol upon various portions of the human system are considered, its value as a food in health sinks into insignificance. For a person in health it must be considered as one of the most wasteful, uncertain, and often deleterious of known substances which are considered foods. In disease, however, when its stimulating and narcotic purposes favor its usefulness, its capability of being rapidly burnt up without undergoing any primary assimilation, and of thus yielding force to an exhausted system, may well make it an invaluable assistant to the physician. The fact, clinically well known, that in disease the human system will burn up much more alcohol than in health, indicates that as a force giver the human system under the circumstances mentioned finds it of peculiar value.

Digestion.—The question of the effect of alcohol upon digestion is an important one. There can be no doubt that very large doses hinder digestion. According to the experiments of W. Buchner (*Deutsch. Arch. f. Klin. Med.*, xxix. 537), ten per cent. of pure alcohol does not affect artificial digestion, while beer, even diluted, retards it. The use even of small doses of alcohol seemed to delay digestion in a few experiments made by washing out the stomach a fixed time after a meal taken sometimes with, sometimes without, alcoholic drink. The method is, however, too crude to allow much weight to the experiments; for it is possible that alcohol may lessen the rapidity with which the food leaves the stomach, and therefore aid in the thoroughness of gastric digestion. Certainly every-day experience teaches us that in small amounts wines and liquors enable the *bon vivant* to digest more than is natural or proper.

Summary.—Alcohol in small doses acts as a stimulant to the ganglionic cells of the cerebrum, and perhaps also to the motor tract of the spinal cord. In large amount it certainly is a depressant to the cerebral and spinal ganglionic cells, as well as the nerve-trunks. The action of small doses upon the respiratory centres is not thoroughly established, but large doses depress the respiratory centres, and finally may cause death by centric paralytic asphyxia. Upon the heart the small dose of alcohol acts as a direct stimulant, the large dose as a depressant or paralyzant. The influence of minute doses upon the vaso-motor system is not thoroughly worked out, but there appears to be a widening of the blood-paths at a time when the heart is still stimulated, so that there is a marked quickening of the blood-movement. The toxic dose of alcohol paralyzes the blood-vessels, probably both centrally and peripherally. The peripheral temperature is often increased by small amounts of alcohol, and there may be even a slight increase in the central temperature, probably caused by quickening of the circulation; the large dose of alcohol depresses the animal temperature, probably by causing vaso-motor paralysis, and thereby increasing heat-dissipation.

In regard to the effect of alcohol upon the nutrition there is much contradictory evidence, but the present probabilities are that the drug has no specific influence upon the production of heat or of carbonic acid, or upon nitrogenous elimination, and that therefore it has little or no direct effect upon the nutrition, unless it be in poisonous doses, when it certainly disturbs all nutritive processes. After absorption into the blood, alcohol is in part eliminated through the lungs, the skin, and the kidneys unchanged, but is largely burnt up in the system, probably yielding force for the working needs of the organism. Whether as a food it is in health of as much or more value than other hydrocarbons is not at present positively known.

THERAPEUTICS.—Our knowledge of the physiological properties of alcohol shows that its chief therapeutic value in acute disease is as a

stimulant, a temporary impartor of power which shall enable the system to stand some strain of like duration,—to bridge over some period of weakness.

The cases to which it is especially adapted may be divided into three classes:

First. Those in which there is a temporary loss of heart-power, as in fainting from exhaustion, loss of blood, or other cause. In these cases the alcoholic stimulant should, if possible, be given hct. and not much diluted; with it should also be exhibited some more rapidly acting diffusible stimulant, such as ammonia.

Second. Those acute diseases in which the powers of the system are in danger of being used up; to aid in the digestion of food and in the maintenance of power. Alcohol, as has already been stated, is to a certain extent a food, but it will not of itself sustain life for a long time, and should in adynamic disease always, unless for special reasons, be combined with milk, or occasionally with eggs. One great source of its value in these diseases is the power it imparts of assimilating food, and in milk-punch are furnished the stimulant to digestion and the most perfect food known for digestion. This use of alcohol is apart from its office in the lowest stage of fever as a heart- and nerve-stimulant. Employed for this purpose it is useful in all stages of the *adynamic fevers*, such as *typhus* and *typhoid*. By the exhibition of three or four ounces of milk every two hours, with one or two drachms of brandy or whisky, from the beginning of the attack, in many cases the development of the severe adynamic symptoms may be prevented.

In the advanced stages of diseases, when the *typhoid state* is well developed, alcohol should be given boldly,—to quiet by stimulation the nervous and circulatory systems,—to afford a food which shall in a measure replace the natural pabulum,—to aid in the digestion of milk and other simple nourishment,—to aid in lowering temperature by checking the tissue-waste of fever: in a word, to enable the system to stand the drain upon its vital powers, and at the same time to check such drain.

Properly administered, it always promotes, not arrests, secretion in these cases. The guide to the amount given should be the effects produced: so long as it lowers temperature and pulse-rate, moistens the dry tongue and skin, and quiets the nervous disturbance, it does good; if, however, the tongue grows drier, the pulse puts on an angry, bounding character, and the patient becomes restless and uneasy, stimulation is being pushed too far, and the amount exhibited should be lessened. Whenever the *odor of liquor appears upon the breath*, the patient is almost certainly *taking too much*.

The antipyretic action of alcohol has suggested its use in cases of high temperature; as, however, this is only one of its actions, and as it is not decided unless very large doses be given, alcohol cannot be employed as a general febrifuge. True arterial excitement and sthenic

inflammation certainly contra-indicate its use. The rule may be laid down as follows: high temperature is an indication for the use of alcohol only when other symptoms also demand it; in itself high temperature is never a contra-indication to alcohol. In *acute sthenic diseases*, after the progressive stage has passed and the results of the disease simply remain to be overcome, alcohol and milk will often save life. Thus, in *acute pneumonia*, when so much consolidation has occurred as to render it doubtful whether the exuded matter can be removed, or in *abscess*, when large amounts of pus have formed, the demand may be very great for alcohol as a food and as an aider of digestion, and sometimes as a stimulant.

Third. Those in which there is a depressing agent. In many forms of *poisoning*, alcohol may be used with signal advantage simply as an arterial and nervous stimulant, to overcome the influence of a depressing agent. Thus, in *snake-bite* the unlimited use of it affords, with the hypodermic use of ammonia (see AMMONIA), the best method of treatment. It has been very strongly recommended in *pyæmia* by Dr. Theodor Clemens, of Frankfort (*Deutsche Klinik*, 1874, 1875), who states that he has seen eight cases of a severe type recover under the administration of red wine in as large amounts as the patient would drink. In *poisoning* by *aconite*, *veratrum viride*, or other similar substance, where death is threatened through failure of the heart-power, alcohol in some form is imperatively needed. In all these cases of acute depression threatening a fatal issue, it should be administered freely, not much diluted, and, if convenient, hot. From one to four ounces of whisky should be given, repeated every ten or fifteen minutes, until slight intoxication, convalescence, or death has resulted.

What has been said up to this point in regard to the therapeutic action of alcohol has had reference to acute disease. The value of the drug in some chronic diseases cannot be doubted; but in prescribing it the physician should never lose sight of the possible danger of producing a habit far worse in its fruits than death itself.

In *chronic neuralgia*, in *hypochondriasis*, in *melancholia*, temporary relief may sometimes be obtained by the use of stimulants; but the very relief afforded doubles the temptation to the frequent use of the alcohol, and, as the system becomes habituated to its action and the dose has to be more and more increased, the habit of frequent stimulation grows almost of necessity into drunkenness. For this reason I do not think the physician is ever justified in prescribing alcohol for its narcotic stimulant effect in these cases. The chief legitimate uses of alcohol in chronic diseases are to aid in digestion, to furnish a food which, without any digestive effort upon the part of the system, shall be absorbed and shall take the place of more ordinary food, and to check excessive tissue-waste. Of course these indications exist only in such diseases as are either dependent upon or closely associated with a condition of system in which the general nutrition is depraved. In

purely local affections the use of alcohol is rarely called for except in the last moments of life, when it may always be employed to afford relief and to protract for a short time the struggle. In *chronic dyspepsia*, alcohol administered with the food often aids very materially in the assimilation of the latter; but care has to be exercised in prescribing it, for the same reasons as were given when speaking of the use of stimulants in melancholia a moment since. In many cases of *chronic neuralgia*, not as a narcotic stimulant, but as a food and a stimulant to nutrition, alcohol is often of the greatest service. The danger of establishing a fatal habit in this disease is, however, excessive. In almost all cases in which alcohol is called for in neuralgia, cod-liver oil is also indicated, and it is generally best to exhibit the two remedies together, so as to obtain the easy assimilation of the oil and to guard against evil moral results.

In *phthisis* and its congener *scrofulosis*, there can be no doubt as to the great value of alcohol; and in the latter stages of consumption its judicious use as an antipyretic narcotic stimulant to lessen the sufferings of the patient is perfectly justifiable. During the chronic movements of the affection, alcohol taken with cod-liver oil, or in small amounts with the food at meal-times, conduces not so much to the comfort as to the well-being and recovery of the patient.

The question as to the propriety of the daily use of alcohol by healthy men is at present a very serious one, involving so many moral and politico-moral issues that it cannot be fully discussed here. Suffice it to state, as obvious inferences from our present knowledge of the physiological action of alcohol, that the habitual use of moderate amounts of alcohol does no harm; that to a certain extent it is capable of replacing ordinary food, so that if the latter be scanty, or even if it be coarse and not easily digested, alcohol, in some form or other, is of great advantage; that in all cases it should be taken well diluted, so as not to irritate the stomach; and that wine or malt liquors are certainly preferable to spirits. The experience of Arctic explorers has clearly shown that alcohol has no heat-producing power, so that at a time when it was believed to have such influence by physiologists the Northern navigators had learned that the free use of spirits, far from enabling a man to withstand habitual exposure to intense cold, very materially lessened his power of resistance. On the other hand, the experience of almost every trout-fisherman or sportsman has satisfied him that spirits do have power to prevent "catching cold" under sudden and unaccustomed exposure to wet and cold, and that benumbed extremities will become warm and have their proper feelings return under the influence of a glass of whisky. There is, however, nothing strange or contradictory in these experiences, and they are both in strict accord with our present knowledge of the physiological action of the drug. As is often the case, the facts were practically made out, however before science could solve the apparent paradox. It has been abun-

dantly shown that alcohol has no heating power; but the chill of sudden exposure, the suffering benumbed extremities, the bronchitis that perhaps follows, all mean simply this: that, as a result of the cold, the blood leaves the surface and the extremities, the circulation fails in the outposts, and, as a consequence, suppressed perspiration—i.e., suspended function of the skin—and internal congestions follow. The relief afforded by the spirits, as well as the prevention of sickness, is due simply to the power of the remedy in maintaining the circulation and keeping the external surfaces warmed by the constantly-renewed currents of fresh blood from the interior of the body.

Owing to its stimulant and antiseptic properties, alcohol constitutes an excellent dressing for wounds, whether accidental or surgical in their origin. It would seem also to lessen pain by a local anæsthetic effect (Morville, *Gaz. des Hôpitaux*, Sept. 1878). Strong surgical testimony as to the local value of whisky has been given by Drs. Blair (*Glasgow Med. Journ.*, Feb. 1870) and Suesseroth (*Phila. Med. Times*, vol. iv. p. 774). Lint soaked and kept constantly wet with spirits is to be packed on or in the wound.

ADMINISTRATION.—Almost enough has been already said upon this point; but a few further remarks seem appropriate. When stimulants are used to sustain the sinking powers in poisoning or in disease, the amount given should be almost solely regulated by the effects. Thus, in snake-bite it may be necessary to give a pint of whisky in the course of an hour; and in low fevers I have seen the greatest benefit result, and life apparently saved, by the exhibition of a quart of spirits a day. The rule is always to be governed by the effects. In poisoning, one, two, three, or four ounces, as the case may seem to need, should be exhibited every ten minutes until some effect is produced or matters become hopeless. In low fevers half an ounce to an ounce should be given every one, two, or three hours, *pro re nata*, the practitioner watching the results, as already spoken of.

The question of choice, of course, comes up in every case as to which of the spirits shall be used. I have never been able to perceive any difference in their action (gin, of course, being excepted), save only that sometimes one agrees better with the stomach than another. This has seemed to me to depend simply upon the personal likings of the patient, to which therefore the choice may well be left. In sudden collapse, some of the wines with a very high *bouquet* are believed to be more stimulating, on account of the others which they contain; but I have had no experience with them. In convalescence, and for habitual use in health, wines are preferable to spirits,—more agreeable, more tonic, and less apt to lead to excessive indulgence.

When a mild stimulant is wanted in the beginning of fevers, especially if milk punch seems too "heavy," wine whey may be sometimes used with advantage. It is made by pouring a half-pint of sherry or madeira into a pint of boiling milk, stirring thoroughly, and, after

coagulation has occurred, straining off the whey, which may or may not be sweetened, according to the taste of the patient. *Mulled wine* is often very grateful to patients as a change. It is made by beating an egg up thoroughly with three fluidounces of sherry and adding a like quantity of water, which must be actually boiling when poured in. *Champagne* is useful in patients with delicate stomachs, especially if nausea or vomiting actually exists, and also may be employed with advantage in sudden failure of the vital powers, especially in elderly persons. It must always be very "dry,"—i.e., as free as possible from sugar.

Milk punch is prepared by adding from a dessertspoonful to a fluidounce of brandy, whisky, or rum, according to the degree of stimulation required and the taste of the patient, to three fluidounces of milk, with sugar and nutmeg to taste. The addition of a tablespoonful of lime-water is not recognized by the palate, and renders the beverage more acceptable to the stomach when the latter is weak.

Egg-nog is still more nutritious than milk punch, but is "heavier," and is usually rejected by the stomach if given too freely. It is made by beating up thoroughly the yolk of an egg with five fluidounces of milk and half a fluidounce to one fluidounce of spirits (and half a fluidounce of lime-water if required), and adding a sufficiency of sugar, with finally the white of the egg previously thoroughly beaten into a froth.

TOXICOLOGY.—The acute form of alcoholic poisoning in its minor degrees is, unfortunately, an hourly occurrence almost in every village, but that fatal results are not absolutely so rare as is generally believed is shown by the fact mentioned by Taylor, that in four years (1863–67) thirty-five deaths from this source occurred in England and Wales. It is worthy of note that in some fatal cases convulsions have preceded death (*Phila. Med. Times*, vi. 463). The absolute diagnosis of acute alcoholic poisoning when the patient is simply seen in the advanced stage of deep coma cannot be made out. The odor of liquor upon the breath or about the person is simply a proof that the subject has been drinking, not that the symptoms are caused by alcohol. The manifestations are merely those of profound compression or congestion of the brain, of apoplexy, of opium-poisoning; and a man who has been drinking only moderately may have been struck down with apoplexy or poisoned with opium. Dr. Hughlings Jackson has recorded a case in which the alcohol impregnated not only the breath but the urine also, and in which the patient was left to sleep it off; but at the post-mortem a clot was found covering nearly the whole of one hemisphere. After death in acute alcoholic poisoning the stomach is found very much congested, and sometimes ecchymosed. The treatment consists in the evacuation of the stomach, the use of the alternate hot and cold douche, and the usual mechanical methods of arousing a narcotized patient.

The results of chronic alcoholic poisoning, by their frequency and

importance, have come practically to rank among diseases, and are discussed in treatises upon the practice of medicine, to which the reader is referred for information. A recent important paper upon the pathological changes produced in the liver and kidneys in chronic alcoholic poisoning in the lower animals, by Dr. C. V. Kahlen, may be found in *Beiträge z. Path. Anat. und z. Allgem. Pathol.*, 9. P. F. Spaiuk finds it possible to produce in rabbits delirium tremens, also chronic alcoholism with tremors (*Moleschott Untersuchungen*, xiv.).

DIGITALIS. U.S.

The leaves of the *Digitalis purpurea*,* or foxglove, of the second year's growth. These are large leaves, of a dull pale green, with whitish down underneath, and have a bitter nauseous taste and a faint narcotic odor. *Digitalis* yields both to water and to alcohol. M. Homollo obtained from *digitalis* many years ago a peculiar bitter substance, which was believed to be the active principle, and was official in the United States Pharmacopœia under the name of *digitalin* (*Digitalinum*). As prepared according to the directions of the United States Pharmacopœia of 1860, it is a whitish or yellowish powder, odorless, but of a very bitter taste, nearly insoluble in ether and in water, readily soluble in alcohol and in acids. With hydrochloric acid it makes a yellow solution, which soon changes to green. This substance, commonly known as *French digitalin*, differs from the *German digitalin* of commerce in being in great part or entirely soluble in water. It is a complex body, and does not entirely represent the medical properties of *digitalis*. As kept in the drug-stores, *digitalin* varies both in strength and in medical properties, and at the 1870 revision of the United States Pharmacopœia it was very properly dropped. In 1871, M. Nativelle announced (*Bulletin de l'Acad. Roy. de Médecine*, 1871, vol. xxxvi.) to the Academy of France that he had discovered a process by which a crystallized substance could be prepared from *digitalis*, and received the grand prize of Orfila.

Crystallized digitalin (*Journal de Chimie Médicale*, 1873) occurs "in short and delicate needle-shaped crystals, and possesses an intense and persistent bitter taste. It is but slightly soluble in water, soluble in twelve parts of cold and six of boiling alcohol of 90°, less soluble in absolute alcohol, and nearly insoluble in ether; very soluble in chloroform. It is rapidly dissolved by a solution of chloral hydrate, the solution becoming greenish blue in color. The concentrated mineral acids dissolve it, hydrochloric acid producing an emerald-green color, sulphuric acid a green which if subjected to the action of bromine fumes

* The question whether other species of *Digitalis* have the therapeutic properties of *D. purpurea* is of great interest. H. Goldenberg (*Ann. Diss.*, Dorpat, 1892) states as the results of his experiments that *D. norrosa*, Steud., *D. gigantea*, Fisch., *D. eriostachya*, Linn., *D. fontanesii*, Steud., and *D. glandulosa* all possess more or less of the physiological properties of the official species, whilst *D. ferruginea*, Linn., is ten times as powerful as the official drug.

changes to a dark red, nitric acid a yellow, nitro-muriatic acid a yellow changing to an obscure green, and a mixture of equal parts of sulphuric and nitric acids a rose-color changing to a deep violet. When heated on platinum, it melts, swells up, becomes brown, and disappears without leaving any traces. It contains no nitrogen, but is composed of 51.33 per cent. of carbon, 6.85 per cent. of hydrogen, and 41.82 per cent. of oxygen."

According to Ch. Blaquart (*L'Union Pharmaceutique*, Nov. 1872), ten per cent. of crystallizable digitalin can be extracted from the crude drug, which probably contains twelve per cent. of it. The question whether this substance is the pure active principle of digitalis is, of course, an important one. The French commission reported as the result of physiological experiments that it produces in man and animals effects similar to those of the amorphous digitalin, but that it is much stronger than the latter. This conclusion has, however, met with some opposition. M. Gubler (*Bulletin de l'Acad. Roy. de Médecine*, vol. xxxvii. p. 404) denies that this crystallized digitalin is stronger than the amorphous preparation, and M. Vulpian in the subsequent discussion asserted that in experimenting he had found them of equal strength, and Ch. Blaquart (*loc. cit.*) in his experiments arrived at a similar result; yet one-ninth of a grain of it is said to have been given to an adult without causing a toxic effect.* Mégerand and Daremberg (*London Medical Record*, 1873, p. 278) have found the crystalline variety the stronger. Dr. Roucher affirms (*Gazette Médicale*, 1874) that the crystallized digitalin is readily convertible into the amorphous or granular variety; but he also asserts (*Les Mondes*, July, 1872) that it is a complex body.† This assertion is confirmed by several chemists, especially by O. Schmiedeberg (*Archiv für Experiment. Pathologie und Pharmacol.*, Bd. iii. p. 19), who affirms that there are in digitalin four active principles: *Digitoxin*, the most active of all, which constitutes the greater bulk of Nativelle's crystallized digitalin; *Digitalein*; *Digitalin*; and *Digitonin*.‡ For a particular account of these substances the reader is referred to the paper of Schmiedeberg.§ The only practical conclusion at present possible is, that it is best to use only official preparations, such as the tincture, which represent the crude drug.||

* For the process of manufacture, see *Boston Medical and Surgical Journal*, p. 25, 1873.

† G. Bouchardat (*Bull. Thérap.*, xc, 81) calls attention to the fact that crystallized digitalin does not, and amorphous digitalin does, polarize light.

‡ *Digitalisarin* and *digitoxiresin* are derivatives respectively from digitalin and digitoxin of Schmiedeberg. A study of their physiological action may be found in *Arch. f. Exper. Path. u. Pharm.*, Bd. iv. p. 191. For a paper on the comparative activity as poisons of the various alleged active principles of digitalis by Dr. Bardet, see *Bull. et Mém. Soc. Thérap.*, 1889-90).

§ Consult also *Schmidt's Jahrbücher*, Bd. clviii. p. 234, for abstract of thesis by Nicolai Görs, of Dorpat.

|| Digitonin is asserted to form the bulk of the soluble digitalin of commerce, and to be the same as *saponin*, the active principle of soap-bark. As saponin has been apparently demonstrated to be the physiological antagonist of digitalis, it is evident that the whole mat-

PHYSIOLOGICAL ACTION.—To the therapist the interest in the physiological action of digitalis centres chiefly upon the circulation. The drug does, however, exert a direct influence upon the apparatus of voluntary motion which is worthy of notice. In toxic doses it lowers reflex activity, and induces lassitude, prostration, muscular tremblings, and sometimes convulsions. That the muscles themselves are affected has been proved by the researches of Vulpian, of Dyb-kowsky and Pelikan, and of Gourvat, all of whom have found that the muscles of frogs poisoned with digitalis respond more feebly than is normal to galvanic currents. The nervous tissue has, however, been found by Gourvat to be more susceptible than the muscular, the nerves losing their functional power sooner and more completely than the muscles.

As the result of an elaborate experimental study (*Reichert's Archiv für Anatomie*, 1871, p. 252), Dr. A. Weil concludes that digitalis first lessens reflex activity by directly—i.e., independently of its action on the circulation—exciting the inhibitory reflex centres of Setzenow, and after a time by directly paralyzing the spinal cord. The experiments upon which this conclusion was based are divided into two series, in the first of which it was found that after small toxic doses of the poison great diminution in the reflex activity of the frog was apparent in from ten to twenty minutes, and continued until the death of the batrachian, but that this diminution for from twenty-five minutes to an hour was immediately suspended by section of the cord high up, the reflex activity returning at once to its normal state; that after large doses the reflex movements were almost abolished in five minutes, and continued until death, but at any time during the first ten or twenty minutes could at once be restored by section of the upper cord; and that, both after large and after small toxic doses, a time finally came when division of the cord had no power to restore the lost reflex functions. These experiments have been confirmed by Dr. Meihuizen (*Arch. f. Physiol.*, vii., 1873). The second of Dr. Weil's series of experiments were directed to discovering whether the action upon the inhibitory reflex centres and the cord was a direct one, or was simply the result of the altered circulation. In this part of the investigation, the hearts of frogs were cut out, or their motion arrested by the local application of a concentrated solution of nitrate of potassium, or rendered slower by a dilute solution of the same salt, and the effects of these various procedures upon the reflex activity were studied. It was found that slowing of the heart's action did excite the Setzenow's

ter is exceedingly confused, and that the conclusion in the text is the only one that can at present be reached. P. H. Laffon, as the result of experiments made chiefly on dogs, comes to the conclusion that the crystallized digitalin of Nativelle, the amorphous digitalin of Hemalle, and the German digitoxin have similar toxic properties. He denies that digitalin is ever eliminated by the kidneys, having always failed to find it in the urine. (*Annales d'Hygiène*, xvi. 506.)

centre, but not to nearly so great an extent as did digitalis, and that minute doses of digitalis sometimes stimulated the Sotschenow's ganglion and lowered reflex activity before the heart was sensibly affected. In regard to the spinal cord it was proved that when the heart was killed by the local action of potash the reflex functions of the spinal ganglia remained intact for a much longer period than when digitalis was administered.

Circulation.—The action of digitalis upon the heart of the frog was, I believe, first investigated by M. Vulpian (*Comptes-Rendus de la Soc. de Biol.*, 1855, p. 70), who has been followed by numerous observers, among whom may be mentioned W. Dybkowsky and E. Pelikan (*Zeitschrift für Wissenschaft. Zoologie*, Bd. xi., 1862), A. B. Meyer (*Arbeiten aus dem Physiologischen Institut zu Zürich*, quoted by Boehm), Legros and Legroux (quoted by Gourvat), Claude Bernard (quoted by Gourvat), Rudolf Boehm (*Pflüger's Archiv für Physiologie*, Bd. v., 1872), Homolle (*Archives Générales de Médecine*, July, 1861), Gourvat (*Gazette Médicale de Paris*, 1871), Fothergill (*Digitalis*, London, 1871), Fagge and Stevenson (*Trans. Roy. Soc.*, London, vol. xiv.), J. F. Williams (*Arch. f. Exper. Path. u. Pharm.*, xiii. 1), and H. F. Gaskell (*Journ. of Physiol.*, iii. 48).

The statements of these investigators agree in all essential points. One or two of them have occasionally noted a primary brief acceleration of the heart's action; but the rarity of its occurrence shows that it has been probably produced by some extraneous unnoted influence.

The first distinctive action of the drug is a marked lessening of the number of cardiac beats per minute, due to a prolongation of the diastole, which may be complete, but is more generally divided by an abortive attempt at ventricular contraction. The systole is abnormally energetic, so that the ventricles become white as the last drop of blood is squeezed out of them. As the action of the drug becomes more intense, the rhythm of the heart is very much affected, the ventricle and auricle no longer beating in accord. At the same time the diastole generally becomes imperfect, one portion of the ventricle maintaining its systolic spasm, while the rest dilates. Thus, the extreme apex may remain hard and white during the diastole, and even hernial protrusions of the ventricle may occur. Finally, the heart is arrested in systole; and as the muscle so hardens, of course all its power of responding to electrical or other excitants is lost.

In some rare instances, instead of the above series of phenomena, the diastolic periods throughout are prolonged and quiet, and after several periods of relaxation, lasting for ten or twenty seconds, final diastolic arrest may occur.

As both Boehm (*op. cit.*, p. 163) and Dybkowsky and Pelikan (*loc. cit.*) have found that the slowing of the heart's beat, the increased energy of contraction, and the irregularity and final systolic arrest are produced by digitalis after division of the vagi and destruction of the spinal cord, and as both Ackermann (quoted by Boehm, *op. cit.*, p. 158)

and Boehm have found that the paralyzing of the peripheral ends of the vagi by atropine does not prevent the phenomena just alluded to, it is evident that the drug acts directly upon the heart-muscle itself, a conclusion which is confirmed by Eulenburg and Ebrunhaus (quoted by Dr. T. Lauder Brunton, *On Digitalis*, London, 1868, p. 51), who found that digitalis, when locally applied, acts at once upon the heart. On the other hand, the inhibitory activity of the peripheral ends of the pneumogastrics is without doubt increased by the drug. There is no stage in which stimulation of the vagi does not cause diastolic arrest. Indeed, Dybkowsky and Pelikan have seen galvanization of nerves produce such relaxation in the auricles after the ventricles had already become permanently contracted. Further, Boehm has found that a stimulation of the pneumogastrics which is insufficient to make itself felt before poisoning will, after the exhibition of digitalis, cause diastolic arrest lasting for many minutes.

It appears, therefore, that the peripheral cardiac inhibitory apparatus shares in the stimulant action of digitalis; and as Boehm has found that diastolic arrest never takes place in frogs poisoned with the drug after section of the vagi, it is probable that this rare mode of death is really due to super-excitation of the inhibitory cardiac nerves.

Rudolf Boehm (*op. cit.*, p. 170) has investigated the influence of digitalis upon the working power of the heart when freed from all connection with the central nervous system. By using the method of Ludwig and Coats, he found as a constant result that the amount of work done was increased by small doses of digitalis; that after large doses a similar increase was followed in a short time by very great diminution in the expenditure of power by the heart, a diminution apparently due to imperfect diastole and consequent non-admission of serum into the viscus. By direct experiment with an artificial circulation Dr. Williams has proved that the cut-out frog's heart actually puts out much more force than normal under the influence of digitalis. Dr. Williams believes that the increased work of the heart is largely dependent upon an altered tone of the muscle, producing a more complete diastolic enlargement of the ventricles. That the systolic arrest of the heart by digitalis is not of the nature of a paralysis but of a spasm is indicated by the fact that there are various paralyzing drugs which, applied to the contracted heart, will cause it to recommence its beat (Schmiedeberg, *Beitr. z. Anat. u. Physiol.*, Festgabe, A. Ludwig). The experiments of François Frank upon the isolated apex of the heart appear to show that it is upon the muscle rather than upon the intra-cardiac ganglia that digitalis acts (*Journ. de Méd. de Bordeaux*, xi. 67).*

* In apparent opposition to all this older evidence are the researches of Messrs. Donaldson and Stevens (*Journ. of Physiology*, iv.). For an elaborate discussion of this paper, and for the reasons why I do not think it should change our views, see editorial in *The Lancet*, February, 1885. H. von Openchawski (*Verhandl. der Congress f. Inner. Med.*, 1889, xiii.) believes that digitalis acts differently upon the right heart than upon the left, and especially

The elaborate experiments of L. Traube (*Gesammelte Beiträge zur Pathologie und Physiologie*, Bd. i., Berlin, 1871) upon warm-blooded animals showed that in dogs moderate doses of digitalis produce increased arterial pressure, with lowering of the rate of the cardiac pulsation. When toxic doses were used, these phenomena were followed by increase of the pulse-frequency and fall of the arterial pressure, which, however, did not commence at the same time, since the maximum pressure was not reached until the pulse had risen above the original, normal point.

The experiments of Boehm, Brunton (*loc. cit.*), Gourvat (*loc. cit.*), and Kaufmann on soluble digitalin (*Rev. de Méd.*, iv.), are in accord with those of Traube: so that it may be considered proved that in mammals moderate doses of digitalis produce rise of arterial pressure with diminished pulse-rate.

Professor L. Traube has found that, after section of the vagi, digitalis is in warm-blooded animals, with rare exceptions, incapable of reducing the pulse-rate, and, contrariwise, that when the pulse-frequency has been reduced by the drug, section of the nerves causes an immediate and very marked rise in the rate of pulsation. I believe Boehm* has experimentally confirmed this, as have also Kaufmann and Gourvat.

It has been suggested that the slowing of the pulse is due simply to the increased arterial pressure, but Kaufmann (*loc. cit.*, p. 389) has noticed the slowing of the pulse without rise of the arterial pressure, and it appears to me demonstrated that digitalis stimulates the cardiac inhibitory nervous apparatus. The experiments of Kaufmann seem to show that in mammals there is not at any time under the influence of digitalis an increased susceptibility of the peripheral vagi; and it is probable that it is the intra-cardiac inhibitory centres rather than the fibres of the vagi which are acted upon. The occasional reduction of the heart-beat in warm-blooded animals by digitalis after section of the vagi (Traube, Kaufmann) shows, however, either that the inhibitory nerves in some animals find another path than the pneumogastrics, or else that there is an additional—sometimes inoperative, sometimes efficient—cause of the reduction of the pulse-rate. As it has been shown that digitalis is capable of slowing the beat of the isolated heart of the frog, it probably exerts a similar influence at times, in mammals, upon the cardiac muscle or its inhibitory ganglia.

Although digitalis does increase the muscular energy of the heart, it seems scarcely possible that the enormous rise of pressure produced by it can be owing to this alone. This *a priori* reasoning has received experimental confirmation from Mallon,† Fothergill (*loc. cit.*), Gourvat

upon the right and the left coronary artery, causing the latter to be overfilled, whilst the former contains no more blood than normal. To my mind his evidence is not sufficient to establish a theory which in itself seems so unreasonable.

* His language is such as to leave the point somewhat doubtful. *Op. cit.*, pp. 188, 189.

† Quoted by Fothergill (*op. cit.*).

(*loc. cit.*), Ackermann (*Ueber die Wirkungen der Digitalis*, in *Volkmann's Sammlung Klinischer Vorträge*, No. 48, Leipzig, 1872), and Boldt (*Inaugural Dissertation*, *Schmidt's Jahrbücher*, March, 1872). The first three of these investigators have found that the arterioles of the frog's web as seen under the microscope undergo very decided contraction after the systemic use of digitalis; and Ackermann states that if the abdomen of a rabbit be opened so as to expose the arteries of the mesentery, a very marked contraction, even to the partial obliteration of the lumen of the vessels, can be readily seen to follow the exhibition of digitalis.

Boldt experimented upon curarized frogs after the manner of Cohnheim, and found that the first effect of the digitalis was marked contraction of the arterioles.

It is stated by Kaufmann that in the latter stages of digitalis-poisoning the peripheral vagi are paralyzed so that galvanic stimulation of their trunks is powerless to affect the heart. This appears to be in opposition to all previous observations, and therefore must be confirmed before acceptance.

According to Boehm, Traube found that, if the spine be divided, digitalis is powerless to increase the arterial pressure, although lessening, as usual, the pulse-rate. The same authority also states that Bezold has seen an excessive fall of the arterial pressure ensue immediately upon the division of the spinal cord in an animal under the influence of digitalis. Further, in his own experiments Boehm has attained similar results, or, in other words, has found that after separation of the small vessels from the vaso-motor nerve-centre, digitalis does not increase arterial pressure.

These experiments would seem to prove that digitalis acts upon the vessels by stimulating the vaso-motor centres in the base of the brain; but they have been contradicted by Ackermann (*op. cit.*, p. 397), who states that he has many times cut the spinal cord and without exception found a very marked rise of arterial pressure follow the injection of digitalis. Unfortunately, none of these experiments have, that I am aware of, been published in detail, and it is therefore impossible to analyze or to reconcile them; but Görz (*Schmidt's Jahrbücher*, Bd. civiii.) expresses the opinion that Ackermann did not fully divide the cord in his experiments. Görz himself found that a rise is produced by digitalin after division of the cord, but of so small an amount as to be readily accounted for by the increased power of the heart.* It is exceedingly probable that Görz's explanation is correct; moreover, it is possible that the cord in these cases was not entirely cut. I have found by actual experiment that a spinal cord may be so divided that the animal has neither sensation nor power of voluntary motion below

* A similar rise has been observed by Kaufmann, who does not, however, give the extent of it (*loc. cit.*, p. 400).

the point of section, although sufficient nerve-fibres retain their integrity to transmit vaso-motor impulses, so that galvanization of a sensitive nerve below the point of section produces immediate rise of the arterial pressure without eliciting any pain-cries from the animal. Dr. J. F. Williams (*Arch. f. Exper. Path. u. Pharm.*, xiii. 1) has also found, after reduction of blood-pressure to zero by chloral, that digitalis will cause rise of pressure. This does not, however, throw much light upon the vaso-motor action of the drug, because by enormous doses of chloral the heart is almost as much affected as is the vaso-motor system. Drs. Brunton and Meyer (*Journ. Anat.*, p. 138) injected digitalin into the ear of a rabbit whose cervical sympathetic and pneumogastrics had been destroyed, but were unable to obtain any satisfactory result; there was certainly no constant perceptible contraction, although sometimes the vessels were seen to empty themselves more rapidly than before the injection. By consentaneous, independent researches, Drs. Ringer and Sainsbury (*Medico-Chir. Trans.*, lxxvii.) and Messrs. Donaldson and Stevens (*Journ. Physiol.*, iv.), using the method of Gaskell more or less modified, have apparently proved that digitalis acts upon the walls of the arterioles. They destroyed the nerve-centres of a terrapin, excised the heart, and connected bottles in such a way with the blood-vessels that liquids would run through the arteries and come out through the veins. Under such circumstances they noted a marked reduction of the rate of flow when soluble digitalin was placed in the artificial serum. That in the normal mammal under the influence of digitalis there is pronounced contraction of the blood-vessels seems to be proved by the experiments of Dr. John C. Hemmator, made with Ludwig's stromuhr, in which it was found that the velocity of the blood-current was markedly decreased by digitalis, though the pressure was increased.

Professor R. A. Kobert* (*Therap. Gaz.*, vol. iii., 1887), in a series of experiments similar in principle to those of Ringer and Sainsbury, but made upon the excised kidney, found that digitalis retards greatly the flow of liquid through the organ, and therefore acts directly upon the coats of the smaller vessels. I think that it must be acknowledged that digitalis has a direct action upon the walls of the arterioles, but it is highly probable that it also acts upon the vaso-motor centre in the medulla.

It has been shown that the diastole in the frog's pulse is due to an attempted diastole before the systolic impulse has yielded; and Kaufmann has determined that in the mammal a similar partial relaxation, arrested by a renewed very brief systole, occurs and gives origin to a double pulse. Kaufmann has also noticed that a tendency to cardiac tetanus is manifested in the horse, as in the frog, under the influence of digitalis, but that in the former animal a permanent, complete

* Professor Kobert tested two specimens of *digitoxin* and *digitalin* which had been supplied by Professor Schmiedeberg, their discoverer, and found that instead of contracting the vessels of the kidney they actively dilated them and increased the flow of liquid.

cardiac spasm never occurs. He has further experimentally determined that the diastolic as well as the systolic intra-ventricular pressure is increased, but that the diastolic intra-auricular pressure is slightly diminished. If it should be hereafter proved that these are constant phenomena, it would appear that the drug acts upon the ventricles rather than upon the auricles.

The following proposition expresses our present knowledge, and probably is very close to the truth:

*Digitalis in moderate doses stimulates the muscular-motor portion of the heart (probably its contained ganglia), increases the activity of the inhibitory apparatus, and causes contraction of the arterioles, probably by an action on the vaso-motor centres in the cord, and also upon the walls of the arterioles. As a consequence of the first action, the cardiac beats become much stronger; as the result of the last, there is narrowing of the blood-paths, and to the passage of the vital fluid an increased resistance, which, acting on the already excited inhibitory system, aids in the slowing of the pulse.**

According to my own experience, decided therapeutic doses of digitalis, in man as in other mammals, produce great reduction and sometimes dirotism of the pulse, and increase the size and force of the wave; at the same time the arterial tension is augmented. Poisonous doses induce, after a time, increase of the pulse-rate, with smallness and weakness of the wave and lowered arterial pressure.

Sphygmographic studies of the effect of digitalis upon persons suffering from various acute and chronic diseases have been made by M. Legroux, M. Bordier (*Bull. Thérap.*, 1868, p. 110), Constantino Paul (*Bull. Thérap.*, 1868, p. 193), and Paul Lorrain (*Journal de l'Anat. et de la Physiol.*, 1870). The problems offered by these gentlemen are so complex as to render a detailed study almost impossible; but, as a whole, their tracings seem to confirm my personal experience. Paul Lorrain calls attention to the fact that when the drug has reduced the pulse-rate very greatly a second abortive systole can, on auscultation, sometimes be heard occurring during the long diastole, and some of his sphygmographic tracings are markedly dirotic. It is evident that in man the second systolic movement occurs precisely as in animals; and it seems very certain that the proposition framed for the lower mammals applies also to man.

When the pulse has been reduced by digitalis to forty or fifty a

* Dr. Bayet (*Acad. Royale d. Méd. d. Belgique*, iv. série, 1892) is stated to have found in the dog that the pressure in the pulmonary artery is depressed rather than increased under the action of digitalis and strophanthus at a time when the aortic pressure is enormously augmented. The importance of this is easily seen: it implies an extraordinary physiological dissociation between the right and left heart, and has also very close relations with the therapeutic use of the agents in pneumonia and other conditions. I have not seen any detailed report of the experiments of Bayet, nor have I seen the memoirs of Bradford and of Buckenham, who are quoted, without reference, as having obtained a different result in 1890.

minute, the change from the recumbent to the erect position will not infrequently suffice to alter at once its character, so that it will become feeble, small, and one hundred and fifty per minute. The explanation of this seems to be that the heart of such a patient is just in the position in which the diastolic impulse is being overcome by the excessive systolic stimulation of the drug. While the patient is recumbent, the line is not passed over, but the additional stimulation of the erect position carries the heart beyond the limit of regular diastole, and the over-effects of the drug are at once manifested.

The fate of the active principles of digitalis in the human system has not been made out, but the experiments of G. H. Roger (*Compt. Rend. Soc. Biol.*, i., 1889) seem to prove that they are not destroyed in the liver.

The influence of digitalis upon the urinary secretion in health has been studied by numerous observers, with such diverse results as to prove that the action of the drug on the kidneys is so inconsistent and varying as to render it probable that it is in great measure indirect rather than direct. Thus, Jörg, Hammond (*Proc. Biol. Dept. Acad. Nat. Sciences*, Phila., Dec. 1858), and Brunton (*loc. cit.*) have found the secretion more or less decidedly increased, and Homolle (*Archives Générales*, July, 1861), Winogradoff (*Virchow's Archiv*, Bd. xxii., 1861), Stadion, and, according to Brunton, also Krahmer, Kluydens, Vassal, and Shohl, have found it either uninfluenced or diminished. Kaufmann has found it uniformly diminished in the dog (*loc. cit.*, p. 411).

The urea in the apparently very careful experiments of Winogradoff (*loc. cit.*), of Stadion (*Prager Vierteljahrs. f. Prakt. Heilk.*, 1862, Bd. lxxii.), and of Hammond (*loc. cit.*), was diminished, while in the almost equally elaborate experiments of Brunton (*loc. cit.*) it was increased. All four observers noted lessening of the chlorides. Mégerand, using the crystallized digitalin of Nativelle, found his urine increased twenty-five per cent. but his urea diminished twenty per cent. Auguste Mousnier has sought without success for sugar in the urine both of patients taking large doses of digitalis and of rabbits poisoned with the drug (Paris Thesis, 1868). Kaufmann (*loc. cit.*, p. 413) states that digitalis leaves, or preparations which produce local irritation, cause in the dog an increase in the elimination of urea, but that when digitalin is given in solution the excretion of urea is diminished. G. P. Sereschnikow, as the result of experiments upon man, finds that digitalis has no pronounced constant effect upon nitrogenous elimination. He is confirmed by Alexeévsky (*St. Petersburg. Inaug. Diss.*, 1890), whilst I. Boljakow makes out that the drug increases the consumption of the chlorides, sulphates, and phosphates (*Schmidt's Jahrb.*, Bd. cccxix., 1891).

It is very certain that toxic doses of digitalis lower the temperature a number of degrees in healthy men and animals. It would seem, however, that the fall of temperature is generally, if not always, preceded by a rise, as has been noted by Bouley and Reynal, by Dumeril,

Demarquay, and Lecoq (quoted by Brunton), by Hirtz, by Legros (*Thèse*, 1867, quoted by Gourvat), and by Gourvat (*Gaz. Méd. de Paris*, 1871, p. 572). Kaufmann believes that such rise is due to the local irritation produced by the drug, and asserts that if no irritation be produced there is always in the animal a fall of rectal temperature ($0.4-0.5^{\circ}$ C.) after even a feeble dose of digitalin.

The effect of *therapeutic* doses in the normal condition has not been closely studied, that I am aware of. But in a number of cases, chiefly of pneumonia, Z. E. Coblentz (Strasbourg Thesis, 1862) found that about twelve hours after the fall of the pulse there was also a fall of temperature. The tendency of our present knowledge is to connect the changes in temperature induced by digitalis with the changes of the circulation; and it seems very possible that therapeutic doses in health may be found to increase bodily heat, although in fever they may diminish it.

Summary.—It would appear to follow, from experiments upon frogs, that the toxic dose of digitalis primarily inhibits reflex action by stimulation of Setschenow's centre, and subsequently directly paralyzes the motor tract of the spinal cord. This influence is not, however, very apparent, even in the lower mammals, and in the human individual the symptoms of digitalis-poisoning are chiefly manifested in irritation of the stomach and disturbance of the circulation, death finally occurring in collapse, sometimes preceded by delirium, stupor, or convulsions, though consciousness is long preserved. The therapeutic dose of digitalis acts almost solely upon the circulation, slowing the rate and increasing the force of the heart's beat by a direct stimulating action on the pneumogastric nerves and upon the heart itself. By this cardiac influence, and also by contracting the blood-vessels through a direct action upon their walls, and also probably upon the vaso-motor centres, the therapeutic dose of digitalis enormously increases arterial pressure. Probably by its direct influence upon the heart-muscle, and also by stimulating the pneumogastric or trophic cardiac nerve, and by increasing the blood-supply of the heart, in certain diseased conditions digitalis acts not only as a cardiac stimulant, but also as a cardiac tonic. After toxic dose the arterial pressure falls, because the ventricles are in such permanent spasm that complete diastole is impossible. The active principles of digitalis are absorbed and probably eliminated through the kidneys, though in health the diuretic action of the drug is extremely uncertain. Upon the alimentary canal digitalis acts as an irritant, affecting the stomach more than the intestines, and often, when in full dose, producing gastric pain and vomiting.

THERAPEUTICS.—The chief clinical use of digitalis is in diseases of the heart; and from what has been said of its physiological action it logically follows that it should be useful in loss of cardiac power.

When the muscle of the heart is for any reason unequal to the task set it, the systoles become rapid and imperfect, and by this irregular

action the ventricles, neither completely filling nor completely emptying themselves, increase the embarrassment. Under these circumstances, digitalis, by lengthening the diastolic pauses and increasing the force of the systolic contractions, causes the ventricles to fill themselves completely in the one and to empty themselves completely in the other act. By subduing irregular action through the inhibitory nerves, and by energizing the muscular power of the heart-walls, the remedy is of incalculable service, and, increasing arterial tension all over the body, causes the disappearance or lessening of symptoms due to low pressure in the arteries.

It is a logical necessity, if our reasoning as to the physiological action of digitalis has led to a correct result, that the drug should be of the greatest service when the lesion is simply loss of cardiac power; and clinical experience tallies with this *a priori* argument. In *simple dilatation*, or in *simple failure of the cardiac muscle* without valvular lesion, the results of the use of digitalis are most favorable.

On the other hand, in *simple hypertrophy* digitalis does harm, and should never be used. It must be borne in mind that although this agrees with what the experimentalist has proved to be the action of digitalis, yet it was discovered independently as a clinical fact by practitioners. Thus, Niemeyer, who ridiculed experimental therapeutics because he would not take the trouble to study them deeply and practically and was therefore incapable of understanding them,—Niemeyer says, "Digitalis in pure uncomplicated hypertrophy is unsuitable."

Valvular lesion of the heart, as is well known, gives rise under unfavorable circumstances to dilatation, but in favorable cases to hypertrophy, or rather in the great majority of cases to hypertrophy with dilatation. Following out the principles already inculcated, it might seem at first that the use of digitalis in hypertrophied hearts with valvular lesion ought to be reprobated. But it is known clinically that digitalis often does good in valvular lesion with enlargement of the heart. The results of logical deductions from our physiological conclusions as promises are, however, not really at variance with this. It must be borne in mind that structural hypertrophy and functional hypertrophy are different things: by this is meant that although a heart be enlarged and absolutely stronger than normal, yet it may be, relatively to the work required of it, *weak*. Thus, if 1 represents the normal work of the heart and 1 its normal power, if the former be increased to 4 and the latter to 3 the heart is really in the position of a weak organ, although possessed of three times its original strength. Hence it is that digitalis is often useful in valvular disease with hypertrophy. In the vast majority of cases the heart with diseased valves is in the position just spoken of; but sometimes the work advances only to 2 and the strength to 3; then the hypertrophy becomes *excess* *vo*, and digitalis will increase the difficulty. In almost all cases the increased power of hypertrophy, unless the muscle be degenerated, renders effectual

smaller doses than can be used in dilatation, and also increases the danger of the over-action of large doses.

In *mitral insufficiency* and in *mitral stenosis* digitalis is often of great service. It is evident that in both instances the valvular lesion leads as its first result to pulmonic hyperæmia. How does the digitalis lessen this? In the case of *stenosis*, the diastole being lengthened by the remedy, the auricle is afforded more time to empty itself into the ventricle through the narrowed orifice, and at the same time is strengthened in its contracting power; evidently, then, the left ventricle when its systole occurs will have much more to contract on than before the digitalis was administered, and the amount of blood in the systemic circulation will be increased,—i.e., the amount in the pulmonic circulation will be diminished; further, the right ventricle will have greater power afforded it to force the blood through the lungs,—i.e., to resist the recoil from the left auricle to which the impeded valve gives origin.

In *mitral insufficiency* the mechanism is different, but the result is the same. The increased power of the systole will throw proportionately more blood through the aortic orifice than through the partially open valve. The opening at the insufficient mitral valve is much smaller and more obstructed than the aortic orifice. As the force or rapidity of the current increases under the action of digitalis, the friction becomes greater at both orifices, but the ratio of increase is evidently far higher in the small choked mitral leak than in the wide aortic opening. Hence the large orifice constantly gains upon the smaller as the cardiac force is increased, and, more blood passing into the systemic circulation, the pulmonic vessels are relieved. Again, the right ventricle shares the stimulant action of the drug, and acts more strongly upon the pulmonic circulation, resisting the direct backward flow from the auricle. There are cases of mitral cardiac disease in which digitalis seems to be indicated, but when given acts unhappily. In some of these cases the augmented distress is probably caused by a strain upon the auricles. If the ventricle be already too strong for the auricle, and if by virtue of a very patulous mitral valve the backing of the blood upon the auricle is very easy, it is readily understood how increasing the power of the ventricle may augment the auricular strain. Especially is this consideration important in the light of Kaufmann's researches, which seem to show that the ventricle is more affected by digitalis than is the auricle, and hence that a stimulated ventricle may have to be met by a non-stimulated auricle.

In *aortic constriction* digitalis is useful when the heart-power begins to fail. In these cases compensatory hypertrophy, with slowness of action, is very apt to occur, or even to become excessive: much more frequently does this happen than in mitral disease. Again, in *aortic insufficiency* the prolonged diastole of digitalis action favors the return of blood to the heart, and is not advantageous. It is evident that

digitalis is not so generally useful in aortic as in mitral disease: nevertheless, when the heart-muscle fails, and the hypertrophy is not compensatory, the drug is useful in both aortic stenosis and insufficiency.*

From the considerations which have been brought forward, it is very evident that a knowledge of the relation of the heart-muscle to the work required of it in any individual case is much more necessary to the therapist than to know what valve is diseased.

In "*irritable heart*" of soldiers, a disease or condition of cardiac irritability evidently connected with muscular weakness, and very probably dependent upon exhaustion of the inhibitory nerves, Dr. Da Costa (*American Journal of the Medical Sciences*, Jan. 1871) found that in the early stages of the affection digitalis not only acted better than any other remedy, but even, when administered continuously for some time, often effected a permanent cure. When hypertrophy had taken place, the drug was of little use.

The relief afforded by digitalis in not too inveterate cardiac disease is often in a measure permanent, because the drug may aid very materially in the production of compensatory hypertrophy. Dilatation is certainly more apt to occur when the muscular fibre is lax and acting feebly than when it is toned up and in vigorous play; secondly, the stimulus to action in a muscle is almost of necessity directly or indirectly a stimulus to its nutrition; thirdly, it appears probable from the researches of Gaskell that the period of inhibition is one of structural upbuilding, and that therefore the pneumogastric nerve is trophic in its nature, so that it is probable that digitalis, by stimulating the trophic cardiac nerve, benefits the cardiac nutrition; lastly, improved systemic circulation means in a far more intense degree improved blood-supply to the cardiac muscle, as is shown by the following considerations.

During systole the cardiac muscle contracts so as to squeeze out completely all the venous blood from the heart-walls. The arterial blood enters during diastole, and the force which drives it into the relaxed walls is derived from the arterial system. The coronary arteries arise nearly at a right angle to the aorta: the blood squirts into the latter during systole in an unbroken stream, and probably does not enter freely the coronary artery. But when the reflux wave comes, the aortic valve flaps to, and the whole pressure of the blood-column forces the liquid into the open cardiac arteries. If the arterial system be emptied, or nearly so, the artories are not distended sufficiently to give origin to a powerful reflux wave, and but little blood enters the coronary artery, i.e., the cardiac walls. The dilated feeble heart is unable during systole to free its walls thoroughly of venous blood, and during diastole the force is lacking for driving in the arterial blood. Digitalis enables the cardiac muscle to free itself thoroughly of venous blood, and at the same time, by restoring to a greater or less degree the normal balance of the circu

* Consult Fothergill, *Antagonisms of Medicines*, Phila., 1873, p. 85.

lation and removing the excess of blood from the general venous system, gives the aorta sufficient blood to provoke an active reflux.*

If in *aneurism*, or in general *capillary atheroma*, there be increased resistance to the circulation, and the heart have not sufficient power to meet this, *digitalis* may be useful, but must be employed with caution. It undoubtedly increases arterial pressure; and this increased pressure may prematurely rupture an atheromatous cerebral capillary or tear open the thinned wall of an aortic aneurism. The use of *digitalis* for the purpose of "quieting the circulation" in aneurism is very dangerous. I have seen immediately fatal hemorrhage produced thereby.

In *cardiac dropsy* *digitalis* is of service probably not only by regulating through the heart the circulation, and by evacuating the surplus fluid through the kidneys, but also by an action upon the vessels. Clinicians do not allow enough for the rôle of the vaso-motor nerves in dropsy. Without saying more as to the clinical side of this question, which I have discussed elsewhere (*American Journal of the Medical Sciences*, July, 1871), it may be allowable to allude to the experiments of Ranvier (*Comptes-Rendus*, 1869, p. 1327), who found that when the vena cava was tied in a dog, and the sciatic nerve of one side cut, œdema occurred only in the leg whose nerve was divided.

Digitalis in large doses is a very valuable cardiac stimulant in *syncope* or sudden collapse from hemorrhage or other cause. (See *Pacific Med. and Surg. Journ.*, 1874, p. 273.) To overcome its slowness of action I have used it hypodermically often with the most remarkable effects. From twenty to thirty minims of the tincture should be injected into the arm, and repeated in half an hour if absolutely necessary, or one-fiftieth of a grain of the digitalin may be substituted. In my experience† the digitalin has several times given rise to severe local irritation, the tincture very rarely.

A number of eminent physicians assert that they have obtained excellent results by the use of half an ounce of the tincture of *digitalis* in the treatment of *delirium tremens*, especially in those cases in which the pulse is very soft and feeble. The evidence of the value and safety of the remedy in such cases is too strong to be overlooked, but does not

* I have let this paragraph stand as in previous editions, although the experiments of Professor Martin seem to show that the circulation is most active in the heart's wall during systole. The appearance of the wall of a diastolic heart as contrasted with that of a systolic heart makes one, however, loath to admit the conclusion that the blood enters the muscles as freely during systole as in the first period of diastole. Moreover, even if Professor Martin's view were adopted, the therapeutic reasoning would only have to be changed in wording, not in drift; the facts remaining that the heart-muscle feels most powerfully failure of arterial circulation, and that therefore cardiac overwork and starvation are apt to go hand in hand, so that the relief of the circulation by the *digitalis* may bring about permanent nutritive changes in the heart-muscle.

† Local irritation, and even the production of abscesses, have also been noted by various observers besides myself. See Witkowski, *Deutsches Archiv f. Klin. Med.*, xviii. 142; also Pei, *Centralbl. f. Med. Wiss.*, 1877, p. 169.

to my mind indicate the possession of narcotic properties by the drug. The rest and sleep which have followed the administration have probably been the result of the cardiac stimulation and the increased flow of blood to the nerve-centres. Enormous doses of digitalis are tolerated in these cases, probably because the heart has become by long habit very much benumbed to the influence of stimulants. Their use is not, however, entirely free from danger.

Closely allied to the last use of digitalis is its employment in *poisoning* by substances such as *muscarine*, *delphinine*, and *aconitine*, which arrest the heart in diastole. Boehm has shown (*Pflüger's Archiv*, Feb. 1872) that in digitalis-poisoning of the frog, even when systolic cardiac arrest has occurred, these substances will often restore the cardiac movements,—a proof that real antagonism exists in their action; and Dobie reports a case (*Brit. Med. Journ.*, Dec. 1872) of recovery after the ingestion of an ounce of Fleming's tincture of aconite, apparently due to the hypodermic injection of twenty minims of tincture of digitalis and the exhibition by the mouth of three doses in an hour of a mixture of tincture of digitalis (one drachm each dose), brandy, and ammonia.

Digitalis is often of great value in various acute diseases,* such as *adynamic pneumonia* and *adynamic fevers*, by maintaining the heart's action. It can have no effect upon the diseases themselves, but may help most opportunely to sustain the heart during a crisis or a period of strain upon it. When in any form of *pneumonia* the right heart is yielding to the strain of forcing blood through pulmonic capillaries pressed upon and reduced in their aggregate lumen by exudation, digitalis may be of the utmost service.

With the idea that digitalis is an active *antipyretic*, it has been prescribed in various acute diseases, sometimes with assorted good results. As already stated, toxic doses of digitalis at first elevate the temperature; and proof is wanting that in healthy men therapeutic doses have any decided influence in depressing the temperature. There seems to be, therefore, no good physiological basis for the antipyretic use of digitalis; at the same time, it is very possible that it may directly or indirectly lower the temperature in disease. Clinical proof of this is, however, still wanting. The strongest evidence in favor of such action is furnished by the records of Professor Wunderlich (*Medical Thermometry*, Syd. Soc. Trans., p 325), according to which from half a drachm to a drachm of digitalis, given in divided dose during three or four days in the second or third week of severe *typhoid fever*, immediately produces a slight fall of temperature in a large proportion of the cases, and sometimes a considerable fall. This fall is said not to last more than a day, when the temperature rises again, but in cases favorably affected

* Consult Hankel, *British and Foreign Medical-Chirurgical Review*, xxxi. 513; Grimsbaw, *Dublin Quarterly*, June, 1873; Anstie, *London Practitioner*, Sept. 1873.

does not regain the original height; the pulse is very much lowered in frequency, and remains about uniform for four days. It is evident that at least in some of these cases of Wunderlich's the drug was given about the time natural desquescence would be expected to occur, and that the slight reduction of temperature brought about at such time does not argue very strongly in favor of the proposition that digitalis is a powerful antipyretic in disease. Far more extensive and complete observations must be made upon a rising, not a falling, temperature, before any satisfactory conclusion can be reached. At present the antipyretic use of digitalis should be purely tentative. In *puerperal fever*, Winkel (*Phila. Med. Times*, 1874, iv.) believes digitalis does good by its action on the circulation, by contracting the arterioles of the uterus and by lowering temperature.

The property of causing contraction of all unstriped muscular fibres has been attributed to digitalis, but, while the probabilities are certainly such as to invite investigation, we have no definite knowledge upon the subject. Mr. Dickenson (*Med.-Chir. Trans.*, vol. xxix.) asserts that it has a powerful action in causing the uterus to contract and to arrest hemorrhage,—a few minutes after an ounce and a half of the infusion is swallowed in *menorrhagia*, severe pains resembling those of the first stage of labor coming on, with a momentary profuse discharge of blood and clots, if there be any present, followed by arrest of the flow for hours. Stadion (*Syd. Soc. Year-Book*, 1862, p. 451) states that digitalis is capable of temporarily but completely annulling the activity of the sexual organs, and that it may be regarded as a true anaphrodisiac. M. Gaunot (*Phila. Med. Times*, iv. 30) makes the same assertion, and advises the use of the drug in *spermatorrhœa*.

The use of digitalis as a diuretic will be considered under that heading.

TOXICOLOGY.—In poisoning by digitalis, the first symptom of any severity is generally vomiting of mucus and bile, very violent and very often repeated. At the same time a feeling of heat of the head, disordered vision, and vertigo manifest themselves. The pulse at this time in the horizontal position may be full and strong and slow, but on the patient's rising becomes weak and rapid. The face is pale. The vomiting continuing, profound prostration comes on, the pulse becomes feeble, small, irregular, although the beat of the heart may be strong and hard. The eyes are very prominent, the pupils fixed and dilated;* according to Tardieu, an almost diagnostic symptom is the blue color of the sclerotic. Abundant salivation sometimes occurs. Intense headache and pains in the back or limbs are often complained of. Diarrhœa is very generally present; the urine may be suppressed. The intelligence is often perfect in the midst of profound collapse, but delirium more or less violent

* Dr. Hauber (*Munch. Med. Wochens.*, 1890) details a case of death, due, according to his belief, to digitalis-poisoning, with contraction of the pupils.

finally comes on. Death, usually preceded by stupor or by convulsions, takes place most frequently in one or two days, but has occurred as late as the tenth day, and as early as three-quarters of an hour.*

In the majority of cases of digitalis-poisoning the patient recovers. When this happens, the symptoms gradually ameliorate. Cardiac weakness, and even a *bruit de souffle*, with more or less exophthalmos,† is said to have persisted for weeks in some cases. In poisoning by digitalin the symptoms are those of rapid digitalis-poisoning,—violent vomiting, intense cephalalgia, and sometimes rachialgia, irregular, feeble, intermittent pulse, and paroxysms of suffocation.

The minimum fatal dose of digitalis is not known. A large teaspoonful of the tincture is said to have caused alarming symptoms in a young puerperal woman (Tardieu, *Clinique*, p. 685, Obs. VIII., Paris, 1867); twenty grains of the extract proved fatal on the tenth day (*Ibid.*, Obs. VI.), and two and a half grammes of the leaves in infusion on the fifth day (*Ibid.*, Obs. X.); fifty granules (gr. one-fiftieth each?) of digitalin have been recovered from (*Ibid.*, Obs. XII., XIV.); about one-fourth of a grain of digitalin (*Gazette Hebdom.*, July, 1874) produced very violent but not lethal symptoms. In the only fatal case of digitalis-poisoning I know of (*Affaire Couty de la Pomerrais*), the amount ingested was unknown.

The treatment, after the evacuation of the stomach and bowels, and the very free administration of tannic acid, as the best, although an unreliable, chemical antidote, should consist in the exhibition of opium and of alcoholic stimulants, with rest in the horizontal position. I know of no recorded experiences with the antagonistic poisons to digitalis, such as aconite or muscarine. As it is possible that while so far as the heart is concerned they may be really antagonistic and yet may intensify the action of digitalis on the cord, their use requires caution.

Two cases, one ending fatally, of what may be considered *chronic digitalis-poisoning*, have been reported by Dr. Köhnhorn (*Lancet*, 1876, i. 583). The symptoms were loss of appetite, tinnitus aurium, vertigo, lowering of the rate and force of the pulse, diarrhoea, weakness, general anæmia, and syncopal attacks. The only lesion found at the autopsy was congestion with ecchymosis of the gastro-intestinal mucous membrane.

ADMINISTRATION.—Digitalis may be given in substance in the form of pills: the dose being one grain three times a day, and increased until some effect is produced. The solid extract (*Extractum Digitalis*, U.S.)

* See case reported by M. Barth, quoted by Tardieu. In a case of poisoning by ten grammes of tincture of digitalis, said to contain twenty milligrammes of digitalin, the symptoms were vomiting, great pain in the head, prostration, a very small pulse,—forty per minute,—anuria, and a systolic bruit heard over the whole heart, having its maximum intensity at the base. Recovery occurred in two days. *Mém. Soc. de Méd. de Bordeaux*, 1884, 397.

† As was first noticed by Lauder Brunton, in dogs poisoned with digitalis a blowing systolic murmur may be at times heard, due to an irregular action of the papillary muscles.

is less reliable than the leaves; its dose is one-fourth of a grain. When a rapid action is desired, one of the following officinal preparations, or the digitalin, should be used: *Infusum Digitalis* (1.5 per cent.),—dose, one fluidrachm to half a fluidounce; *Tinctura Digitalis* (15 per cent.),—dose, five to twenty drops; *Extractum Digitalis Fluidum*,—dose, one to two drops.*

In emergencies where single doses are administered they may be very much larger than those here given. Thus, of the tincture two fluidrachms or even half an ounce may be exhibited; of the infusion, a wineglassful. Moreover, in desperate cases, the physician is justified in taking the risk of the administration of repeated very large doses of digitalis. I have seen a number of cases of excessively severe chronic cardiac failure, with Cheyne-Stokes respiration, orthopnoea, and almost absolute insomnia, in which the administration of half a drachm or a drachm of the tincture of digitalis three or four times a day has enabled the patient to resume for a time the ordinary duties of life. In almost every case of this character which I have watched, death has finally come by sudden syncope, while the patient was still going about and enjoying a comfortable life. I do not believe that the arrest of the cardiac action has been due to a direct action of the drug, but simply that the enormous doses of digitalis have stimulated the heart and stendied its expenditure of force, so that it was enabled to go on until the last particle of cardiac vital power was exhausted. I may further say that in the experience of twenty-five years in which I have used digitalis, frequently in enormous doses, I have never seen a case in which I thought it did serious harm by a toxic action. The infusion of digitalis is believed by many practitioners to be more active than the tincture. This is simply because the infusion is commonly used in much larger doses than the tincture. Either preparation is efficient if properly made from fresh leaves.

When digitalis is administered persistently, its first evident influence may be suddenly developed after long delay (*case, Phila. Med. Times*, vol. ii. p. 24). It is said that sometimes the first marked symptom of this so-called cumulative action is severe syncope, followed by paraplegia, vomiting, diarrhoea, delirium, general insensibility, and death. Such cases must be extremely rare: usually a sudden drop of the pulse is the most serious effect, provided that the administration of the remedy be at once suspended. It is a matter of much importance to determine when this cumulative action is to be expected. It is probably connected with slow absorption and elimination, and is much more prone to occur when there is no diuretic effect. It is also very apt to appear after tapping: the sudden removal of pressure from the vessels leads to the picking up from the tissues of serum,—saturated, it may be, with digitalis principles,—and also to the rapid absorption of any digitalis which may

* According to Fraenkel's experiments, the most certain preparation of digitalis is the vinegar; then comes the infusion, and finally the tincture (*Charité-Annalen*, 1851, 225).

be in the alimentary canal. Drs. T. Lauder Brunton and J. Theodore Cash (*Lond. Practitioner*, xxxiii. 272) find that high temperature so weakens the cardiac inhibitory apparatus in the cat that it will not respond to digitalis, and believe that this direct action of the bodily heat is in many cases of fever the reason why digitalis will not act. They caution against its too bold use in diseases with a sudden deferrescence, because when the temperature suddenly falls, inordinate digitalis effects may appear. It should be a general practice in the persistent administration of digitalis to interrupt its use occasionally so as to allow a clearance of the system.

As already stated, the *digitalin* of commerce is a complex body of various composition, power, and even properties, and there is no sufficient reason for its employment. Even for hypodermic use the tincture seems preferable, as the digitalin solution appears to undergo change in a few hours, and usually causes more irritation when injected than does the tincture. The dose of *digitalin* is one-fiftieth of a grain. *Digitoxine* has been used to some extent by European clinicians. M. Masius (*Bull. Acad. Roy. de Med. de Belge*, vii., 1893) states that the digitoxine of Merc acts with great promptness and efficiency, and does not irritate the alimentary canal. He dissolves one and a half milligrammes in forty centigrammes of chloroform, ten grammes of alcohol, and fifty grammes of water, giving one-third every three hours until the whole has been taken. The result is usually manifest in twelve hours. One and a half centigrammes may be given in each twenty-four hours for several days.

CAFFEINA—CAFFEINE. U.S.

Caffeine occurs in long, snow-white, silky, opaque, odorless crystals, sometimes conjoined into feathery crystals, of a feeble bitter taste. It has a neutral reaction, but unites with acids to form salts. It is soluble, at 59° F., in 80 parts of water, 33 parts of alcohol, 555 parts of ether, or 7 parts of chloroform. It was first discovered in coffee by Runge (*Schweigg. Journ. Chem. Phys.*, xxxi.), in 1820. In 1827, Oudry discovered a principle in tea which he called *theine*, which in 1838 was proved by Mulder and C. Jobst to be identical with caffeine. Martius, Stenhouse, J. Attfield, and other chemists have also shown that caffeine is the active principle of *Guarana* (the fruit and leaves of the *Paullinia sorbilis* of Brazil), of *Mate*, or *Paraguay tea* (the leaves of the *Ilex Paraguariensis*),* and of the *Kola nut* of Africa (*Cola acuminata*). H.

* *Mate* is used in South America very largely as a substitute for tea. According to the analyses of Dr. Peckolt, of Rio Janeiro, it contains 2.5 parts in a thousand of caffeine; but M. Blyman found 1.85 per cent. of the alkaloid (*Bull. Thérap.*, xciii.). It is sold in two forms: *mate en leaf* is prepared as ordinary tea is, and taken with sugar and milk to taste; *mate en powder* is prepared by pouring upon the powdered mate boiling water, and the infusion is racked up through a tube, the bulbous end of which is furnished with a fine sieve, or the powder is thrown into boiling water, and when the mixture recommences boiling, cold water is poured into it; this precipitates the powder, and the infusion is taken clear.

M. Smith (*Journal of Applied Science*, Sept. 1874) has also found it in *Yaupon* (the leaves of our native *Ilex Cassine*). Commercial caffeine is obtained in great part from tea which has been more or less damaged during transmission or has been originally unfit for beverage.

PHYSIOLOGICAL ACTION.—The peculiar wakefulness, the increased mental activity, and the nervous restlessness which are induced by strong coffee are familiar phenomena to almost every one. They are without doubt largely, if not altogether, due to the caffeine contained in the beverage.* By doses of four or five grains of the alkaloid a somewhat similar state of body and mind may be induced. Lohmann found that

M. L. Lapicque (*Compt.-Rend. Soc. Biolog.*, vol. ii., 1890), in comparative experiments made upon himself, found that kola nut and caffeine had exactly similar effects. Edouard Hecke (*Rept. de Pharm.*, October, 1892) claims that whilst the kola nut has a muscular action similar to that of caffeine, its stimulating effect is more powerful and more prolonged. For an elaborate account of the nut, see *Die Kola Nuss*, Bernard Schuchardt, 1889.

Chemically the alkaloid obtained from tea and known as *theine* is identical with caffeine; indeed, most of the caffeine of commerce (Dr. Charles Rice, *American Druggist*, March, 1886) is obtained from the tea leaf. If, however, the experiments of Dr. Thomas J. Mays are confirmed, theine is not physiologically identical with caffeine. The argument that tea and coffee differ in their gross effects on the human body, and that therefore the alkaloids cannot be identical, has no force, because coffee contains an empyreumatic oil which is made during the process of roasting, and is not found in tea. Dr. Mays asserts as the result of his experiments, made chiefly upon frogs, that theine differs from caffeine as follows: 1. Theine principally influences sensation, while caffeine does not. 2. Theine produces spontaneous spasms and convulsions, while caffeine does not. 3. Theine impairs the nasal reflex early in the poisoning process, while caffeine does not, if at all, until in the very last stage. 4. The lethal dose of theine is larger than that of caffeine. Dr. Mays also claims that theine is a powerful local anæsthetic, while caffeine is not. The comparison of the various papers of Dr. Mays (*Trans. Coll. of Physicians*, Phila., 1886, viii. 365; *Journ. of Physiology*, vii. 458; *Therap. Gaz.*, 1885, 1886; *The Polyclinic*, vol. v.) does not seem to me to confirm all these alleged differences, which also are at variance with the results obtained by Brunton and Cash (*Journ. Physiology*, vol. ix.), and the matter must still be considered as *sub judice*. The clinical results obtained by Dr. Mays are sufficient to warrant the trial of theine citrate injected in a dose of a third to a half of a grain over painful nerves or inflamed parts as a local anæsthetic.

Guaranine is also thought by Dr. Mays to be distinct in its physiological action from caffeine. Indeed, it seems to stand half-way between theine and caffeine in its influence. It does not seem certain that the alkaloids which were used by Dr. Mays were pure and genuine.

• The infusion of roasted coffee differs in its action on human individuals so much from tea, and according to general belief from the infusion of green coffee, that as long ago as 1853 Dr. J. Lehmann experimented with the empyreumatic oil of coffee, and reached the conclusion that it was an active substance. The results obtained by the various experimenters upon what has been called by some *caffeine* have been strangely contradictory, and it does not seem necessary here to follow out this matter in detail, but only to call attention to the recent researches of Professors Hare and Marshall (*Med. News*, Phila., vol. lii.), and of Professor E. T. Reichert (*Ibid.*, vol. lvi., 1890), whose papers contain a discussion of the whole evidence. Hare and Marshall believe that they have proven that the empyreumatic oil is active; Reichert, however, believes that the changes produced by it in these experiments were due to mechanical alterations in the circulation by the insoluble oil; claims to have obtained the same results by the intravenous use of pure olive oil; and asserts that the oil of coffee given subcutaneously has no general effect upon the organism. It seems to me, however, that further researches are necessary before the claims of Professor Reichert, that the empyreumatic oil of coffee is inactive, can be considered as established, and that in any case there must be formed some active principle, volatile or otherwise, during the process of roasting coffee; probably the caffeine itself is in part changed into some new compound.

eight grains of caffeine produced increased frequency of the pulse, very frequent urination, tremulousness, excited mental action, passing into a form of delirium, with confusion of thought, visions, and finally a deep sleep. About two hours after taking twelve grains, Dr. Pratt was seized with intense physical restlessness, conjoined with a very uneasy condition of the mind; very marked general muscular tremulousness soon followed, and the mental anxiety increased. After this state passed off, there was obstinate sleeplessness, with active and persistent thinking, and frequent urination.

The influence of the alkaloid upon frogs has been studied by Albers (*Deutsche Klinik*, 1853, p. 370), Falek and Stuhlmann (*Virchow's Archiv*, Bd. xii. p. 365), Mitscherlich (*Der Cacao und die Chocolate*, Berlin, 1859), I. Hoppe (*L'Écho Méd.*, 1858), Brill (*Inaug. Diss.*, Marburg, 1861), Oscar Johannsen (*Inaug. Diss.*, Dorpat, 1869), and various other observers. The minimum fatal dose is stated by Leven (*Arch. de Physiol.*, 1858) to be .015 grain in a frog of moderate size. According to the various observers, the chief symptoms induced by poisonous doses in the batrachian are muscular quietness and weakness, with disturbance of respiration, succeeded by a stage of violent tetanic convulsions, ending in general paralysis and death by asphyxia, the heart beating after the cessation of respiration, although evidently much affected.

Johannsen denies that there are any true convulsions produced in the frog by caffeine, but merely a rigidity, muscular in its origin and very closely allied to that produced by heating a muscle,—i.e., to post-mortem rigidity. Pratt, however, previous to the publication of the paper of Johannsen, had very clearly recognized the existence both of this muscular stiffness and of convulsions, and had pointed out the differences between the latter and those of strychnine, differences which are the result of the peculiar condition of the muscles in caffeine-poisoning. He says, "At the commencement there is the usual rapid action and abrupt contraction of the muscles; but as the phenomena go on, the muscles seem to act sluggishly, requiring quite an interval to contract and relax, . . . the spinal cord having to deal with muscles already much contracted by the local action of the poison on their fibres." Moreover, Leven (*loc. cit.*, p. 182) destroyed entirely the lower third of the spinal cord in a frog, and administered caffeine, when the characteristic convulsions appeared in the upper two thirds of the animal, but not in the lower third.

Pratt included all the tissues of a frog, except the spine, in a tight ligature just above the bifurcation of the aorta, and administered caffeine, when the anterior legs became very stiff, and had also occasional severe convulsions, in which the hind legs participated, although between the paroxysms they were perfectly relaxed. He also noted in a number of experiments that the hind legs became very rigid, but not convulsed, after the lower portion of the spinal cord had been removed and the animal poisoned.

Buchheim and Eisenmenger (quoted by Schmiedeberg) corroborate the muscular changes noted by Johansen, but insist, with Pratt, that there are also true nervous convulsions. O. Schmiedeberg (*Archiv für Exper. Pathol. und Pharm.*, Bd. ii.) believes that he has reconciled these differences of observations by finding that the alkaloid acts much more powerfully upon the muscles of *Rana temporaria* than upon those of *Rana esculenta*; so that a dose of caffeine which causes intense general muscular stiffness in the former produces in the latter only true convulsions, the convulsions in *R. temporaria* being prevented or masked by the disorder of the muscles. The most recent researches (E. Leblond, *La Caffeine*, Paris, 1883; W. Filehne, *Arch. f. Anat. und Physiol.*, 1886) indicate, however, that the differences depend to some extent upon the size of the dose, but in still greater degree upon variations in the sensitiveness of individual frogs; thus Kobert (*Arch. f. Exper. Path. u. Pharm.*, xv.) found that frogs of the same species are very much more susceptible in the spring than in the autumn. The rigidity and paralysis are muscular, and the elaborate studies of Leblond appear to prove that there are two stages (as in veratrine-poisoning) in the action of caffeine upon the frog muscle,—a primary stage, with exaggerated muscular excitability and a tendency to prolonged tetanic contractions and momentary stimulations, and a final stage of rigidity and lost excitability.

The action of caffeine upon the muscle is readily demonstrated by throwing the isolated gastrocnemius of the frog into a one-per-cent. or even a weaker solution; in from two to three minutes the muscle becomes contracted, swollen, round, stiff, and unable to respond to the galvanic current. That it is the muscle-fibre that is affected is shown by the experiments of Pratt and Voit, already quoted, in conjunction with one in which Pratt found that when an isolated muscle was soaked in a solution of curare until the nerves were killed, and then thrown into a solution of caffeine, the usual rigidity was developed. Johansen (*loc. cit.*, p. 22) states that when a muscle under the microscope is touched with caffeine, its fibres can be seen to contract half their length; and Paschkis and Pnl, in a series of elaborate experiments (*Med. Jahrbücher*, 1886), found that caffeine, theobromine, and xanthine first augment and then destroy the contractility of the frog's muscle with which they are brought in contact. Caffeine (trimethylxanthine) was the strongest; theobromine (dimethylxanthine) the next in power; xanthine the weakest.

In lards poisoned with caffeine, the symptoms (Brill, *loc. cit.*, p. 66) are irregular movements, apparently to some extent due to cerebral disturbance, increased rapidity and irregularity of respiration, spasmodic tremblings, and tetanic and clonic convulsions, with paralytic phenomena. In mammals the results of the toxæmia, as noted by various observers,* are restlessness, hurried respiration, at first a slight

* Leven (*Archives de Physiologie*, 1868; Amory (*Boston Medical and Surgical Journal*, i, 1868); Pratt (*ibid.*, ii, 1868); Alex. Bennett (*Edinburgh Medical Journal*, Oct. 1873).

lowering and afterwards a decided elevation of temperature* (Alex. Bennett), muscular weakness, tetanic and clonic convulsions, increasing general paresis, and finally death, apparently from paralytic arrest of respiration. There is still a good deal of uncertainty as to the nature of the convulsions; but Amory in some not very conclusive experiments found that they did not occur below the point at which he had divided the cord. If this result be correct, the convulsions must be cerebral; but confirmation is lacking. Uspensky (*Reichert's Archiv*, 1868, p. 526) has found that forced artificial respiration in great measure suspends the convulsions.†

Nervous System.—There is no evidence that caffeine exerts a very marked influence upon the cerebrum of the frog, or even of some of the lower mammals, unless the convulsions induced by it are believed to be the result of some such action. In certain of the higher animals, such as the cat, it often produces a condition of almost frantic cerebral excitement. In man the increase of brain-power produced by coffee, tea, guarana, and other drugs containing caffeine and the allied alkaloids is undoubtedly real, and we must conclude that caffeine is a powerful stimulant to the cerebral cortex. It appears to me to be our most certain and effective stimulant of the nerve-centres connected with the intellectual functions. Those centres whose function is consciousness are greatly stimulated, and wakefulness results, while again, in contrast with opium, caffeine increases the activity and power of the reasoning faculties, at least as much as it does that of the imagination. Coffee prepares for the active work, both mental and physical, while opium leads its votaries among the reveries and dreams of a poet.

The convulsions produced in the frog by caffeine seem to be spinal. Both Pratt and Leblond have found that section of the cord high up does not prevent them, so that they are not cerebral; while in Pratt's experiments, as well as in those of Leven, destruction of the spine prevented their development. The conclusion seems established that in the frog caffeine acts as a motor spinal stimulant and also as a muscle-poison.‡ The physical restlessness and tremulousness produced in man

* Attention has recently been called, especially by Professor Bins, to the effects of caffeine upon animal temperature. He states that minute doses have no effect upon the bodily temperature; doses just enough to produce slight toxic symptoms cause a rise of 0.6°C .; excessive doses cause an elevation of 1° to 1.5°C ., the maximum being reached in one to two hours; doses which rapidly kill have very little effect upon the temperature (*Arch. f. Exper. Path. u. Pharm.*, ix. 31).

† In an elaborate series of experiments, Dr. Bennett (*British Medical Journal*, 1874) found that the minimum fatal dose of the poison for the cat and the rabbit was a little over a grain for the pound, five and a half grains being required for a five-pound animal.

‡ Alex. Bennett has brought forward the theory (*loc. cit.*, and *British Medical Journal*, 1874) that caffeine paralyzes the posterior columns of the cord without affecting the anterior columns, but his evidence appears to me insufficient to prove his conclusions. He grounds his belief chiefly on finding that in poisoned frogs and rabbits galvanization of the posterior columns of the exposed cord produced either no muscular contractions or only such as were very much more feeble than those provoked by galvanization of the anterior columns.

by excessive doses of coffee and tea are probably rather spinal than cerebral.

The *motor nerves appear not to be affected*, since Alex. Bennett has found that after death from theine they retain their normal susceptibility, and Pratt surrounded one crural nerve of a frog with a paste "of theine and water," and irritated the spinal cord, when both legs responded with uniform alacrity. Bennett also tied the crural artery of a frog, poisoned it with the alkaloid, and found that irritation of the cord produced equally active contractions in the two legs. Upon the sensory nerves it is affirmed that the poison acts more decidedly. The chief evidence is furnished by Pratt, who found that when the left sciatic nerve of a frog was surrounded by a paste of theine and water, after ten minutes irritation of the right foot produced reflex movements, while irritation of the left foot failed to elicit any response. Leblond has noted marked hyperæsthesia in the frog, and Rumpf affirms (*Schmidt's Jahrb.*, Bd. cci. p. 123) that increased sensibility of the skin can be demonstrated in man.

Circulation.—Caffeine has a direct influence upon the heart, although that viscus continues to beat in animals poisoned by the drug after the cessation of respiration. According to Voit (quoted by Brill), in the frog the rapidity of the cardiac pulsation is at first increased, but the pulsations become slower and slower, and are accompanied by irregularity of rhythm, the heart finally ceasing to act, but still responding to stimuli at a time when the voluntary muscles are absolutely dead. Falk, Stechlmann, and Johannsen observed that caffeine first increases and then lessens the frequency of the cardiac pulsations in the frog. According to Johannsen, the lessening of the frequency comes on the more quickly and the more powerfully as the size of the dose is increased. After a time the heart begins to beat irregularly, with short intermissions, which, as time goes on, grow longer and longer, till at last movement ceases. Johannsen found that the action upon the cut-out frog's heart was the same upon the viscus *in situ*; Leblond confirms this, and states that the heart is finally arrested in *astole*; so also does Dr. Thos. J. Mays (*Therap. Gaz.*, 1885, i. 84).

Aubert and Haase (*Pflüger's Archiv*, v. 608) find that the action of the alkaloid upon the pulsations of the frog's heart varies greatly; and indeed the individual experiments of the authors previously quoted show such variation. This is confirmed by the research of Dr. Rioschiro Maki (*Inaug. Diss.*, Strassburg, 1884). This investigator experimented upon the cut-out frog's heart with the Williams apparatus, and found that the pulse was variously affected. In most of his experiments the arterial pressure—i.e., the heart's work—was markedly lessened, but in a few cases it was distinctly increased. In the seventh edition of this work it was said that the evidence thus far brought forward indicated that caffeine exerts a double influence upon the frog's heart,—in small doses stimulating it and increasing its work, and in larger

doses paralyzing it. This conclusion seems to be in accord with the more recent researches. Thus, Paul Faval (*Thesis*, Lyon, 1887, 357) finds that in a proportion of ten centigrammes to one hundred and fifty grammes of artificial blood the alkaloid reinforces the isolated frog's heart, giving its contractions more amplitude and more energy, but that stronger doses depress the heart, and finally arrest it in diastole; and Dr. H. C. Beyer (*Amer. Jour. Med. Sci.*, July, 1885) has reached similar conclusions with the heart of a terrapin.

The results obtained by various experimenters upon mammals are in their general appearance contradictory, but are, however, I believe, reconcilable. In attempting such reconciliation it seems better to discuss separately the effects of the drug upon arterial pressure and pulse-rate. In the Aubert and Haase (*Pflüger's Archiv*, v. 608) experiments, caffeine usually produced pronounced fall of the arterial pressure, although in one experiment there was a distinct rise. It is to be noted that the research was made with enormous doses of caffeine, and usually upon dogs under the influence of narcotics. In two experiments upon alcoholized dogs, Professor Binz (*Archiv f. Exper. Path. u. Pharm.*, ix. 36) obtained a pronounced rise of the arterial pressure; while Maki (*Inaug. Diss.*, Straassburg, 1884), experimenting upon animals under the influence of atropine or chloral, obtained after large doses a distinct fall of the arterial pressure, which in a few cases was preceded by a rise. It is evident that the method of research employed in these experiments makes it impossible to draw any very positive conclusions. In normal animals, Leven found in the first stages of caffeine-poisoning a distinct increase of the arterial pressure, and in the elaborate experiments of Professor Reichert (*Therap. Gaz.*, 1890) it was noted that in the normal dog caffeine injected into the jugular vein, in moderate amount, caused a primary fall of pressure, followed by a rise above the norm, followed in turn, if the dose had been large enough, by a marked fall of pressure. Very large doses of caffeine produced a persistent fall of pressure, ending in final diastolic arrest of the heart. It is plain that the primary fall of pressure was simply due to the caffeine first reaching the heart in concentrated dose, yet, although in none of the experiments was the rise of pressure very great, unless very large doses were employed it occurred almost invariably. Leven asserts that after he had divided the pneumogastrics and sympathetics, and isolated the heart from all the nerve-centres, caffeine still increased the arterial pressure; while Professor Reichert states that not only is the increase of the pressure seen when the animal is motionless with curare, but also after destruction of the vaso-motor centres in the medulla oblongata.

The evidence, therefore, seems conclusive that caffeine increases the arterial pressure independently of the vaso-motor centres. Professor Reichert believes the rise to be due to an action on the muscle-fibres in the walls of the blood-vessels. But we have no direct proof of the correctness of this, while all the experiments upon the frog's heart (see preceding

paragraphs) indicate that in *small doses* the drug acts upon the heart as a direct stimulant. Nevertheless, the theory that the muscle-fibre in the arterial walls shares in the general action of the alkaloid upon the muscles has probability.

In the advanced stages of caffeine-poisoning, *both the heart and the vaso-motor system are without doubt depressed*, so that the cause of the fall of pressure is duplex.

In regard to the pulse, Aubert notes as a constant effect an increase of the pulse-rate, and this appears to be the most frequent result produced by caffeine; but it has been shown by Reichert that under certain circumstances there is a slowing of the pulse. Leven asserts that the increase of the pulse-rate is to be seen after isolation of the heart from the nervous centres, and is, therefore, due to an action upon the heart itself, a conclusion which is in accord with the general results of observations upon the isolated frog's heart, and is confirmed by Reichert, who believes, however, that, in addition to such action, there is paralysis of the cardio-inhibitory centres, both in the medulla oblongata and the heart. The slowing of the pulse occasionally seen in the first stages of the poison Reichert attributes, with probable correctness, to a primary stimulation of these cardio-inhibitory centres; the alteration of the pulse which sometimes occurs in advanced poisoning he thinks to be due to a direct action of the drug upon the heart.

Diuretic Action.—In poisoning by caffeine great increase in the secretion of urine is a common symptom, and the statement of Professor Gubler (*Bull. Thérap.*, xc. i. 523), that the alkaloid is one of our most powerful and certain diuretics, has received abundant confirmation. The effect of the drug upon healthy men would indicate that in dropsies it does not act simply by regulating the circulation of the kidney, but has also a distinct effect upon the renal organ itself. That this surmise is correct is proved by the experiments of W. von Schröder and of A. Langgard (*Centralbl. f. Med. Wissen.*, 1886; also *Arch. f. Exper. Path.*, xxii., 1887), who separately found that when a canula was inserted into the ureters in an animal whose vaso-motor system was completely paralyzed by chloral, injections of caffeine into the circulation caused a very great increase in the urinary secretion. Langgard found that usually before the great increase of diuresis the urinary secretion was arrested for several minutes. This is in exact accord with the experiments of Dr. C. D. T. Phillips (*International Med. Congress*, Washington, 1887) made with Roy's oncometer. It was found that immediately after the injection of a small dose of caffeine, when the blood-pressure was either slightly depressed, elevated, or unaffected, the kidney underwent a very distinct contraction of its volume, which lasted for two or even three minutes and was accompanied with great lessening or arrest of the urinary secretion. After the contraction the kidney rapidly expanded beyond its original bulk, and at the same time the urinary secretion became excessive. These various experiments prove that the

action of caffeine upon the renal secretion is entirely independent of its influence upon the general circulation. Dr. Phillips's facts do not, however, as he seems to think, prove that the diuresis is caused by the increase in the flow of the blood to the kidneys. It is more probable that the condition of the local blood-vessels is the result of the action of the drug upon the renal secreting organ; especially is this the case since Schröder found that the division of all the renal nerves did not prevent the increase of the secretion under the action of caffeine. Because the secretion from the uninjured kidney was increased much more than from the kidney whose nerves were destroyed, Professor Schröder believes that the drug increases diuresis by acting both upon the nerve-centres and upon the secreting structure of the kidney. To my thinking, however, the direct injury to the secreting apparatus of the kidney by division of the renal nerves is sufficient to account for the difference between the influence of the alkaloid upon the normal and the operated-upon kidney, without necessitating the theory of a two-fold action. Professor Schröder found that there was an increase not only of the liquid, but also of the solids of the urine.

The enormous use made by mankind of substances containing caffeine indicates that in some way it is directly of service in the wear and tear of daily life. It is not probable that any of the caffeine is assimilated, but it is thought by some authorities to check very greatly the elimination of nitrogen, or, in other words, to lessen the waste of tissue. This subject was laboriously investigated by Julius Lehmann in 1853, and by F. W. Böcker in 1854, and earlier. Dr. Lehmann found that the exhibition of six grains of caffeine daily, the regulated diet being uniform, diminished the elimination of urea from twelve to twenty per cent. Upon experimenting with the empyreumatic oil of coffee he found that it lessened even to a proportionately greater extent the elimination of urea, and also acted very powerfully in producing sleeplessness, so that the favorite beverage is by no means dependent upon its contained caffeine for all of its activity. Dr. Böcker published his researches on coffee in 1849 (*Beiträge zur Heilkunde*, Bd. i.), but I have never seen any abstract of the article, other than the statement that he found that the drug causes diminished elimination of urea. His investigation of the effect of tea was most elaborate and laborious (*Archiv der Vereins für Gemeins. Arbeiten z. Förderung d. Wissen. Heilkunde*, Bd. i. p. 213). He analyzed the feces, the urine, and the products of respiration, and found, a similar diet being maintained, that tea did not affect sensibly the elimination of carbonic acid from the lungs, but did very decidedly diminish the excretion of urea, and also of nitrogenous matters in the feces. He then tried abstaining from food for periods of thirty-six hours, with and without the use of tea, with results perfectly in accord with those just stated. The results obtained by various experimenters are singularly discordant. Henri Hoppe (*Deutsche Klinik*, 1857), in experiments upon a dog, found that

coffee diminishes very slightly the urea-elimination, but greatly increases the output of carbonic acid. In regard to urea, Rabuteau and his pupil Eurastratiade, working with coffee upon men and dogs, obtained results similar to those of Böcker (*Comptes-Rendus*, 1870, lxxi. 426, 732), as did also Hammond in this country. On the other hand, C. G. Lehmann (*Lehrb. d. Physiolog. Chemie*, Bd. i., Leipsic, 1842), Voit (*Untersuchungen*, Munich, 1860), and Roux (*Arch. de Physiol. Norm. et Path.*, 1874, i. 592) found that caffeine or coffee sensibly increases the elimination of urea, or, in those accustomed to the daily use of coffee, has no influence.

In a long series of experiments upon dogs by MM. Conty, Guimaraes, and Nioboy, it is affirmed as a uniform result that the use and assimilation of nitrogenous food were greatly increased, that the carbonic acid and oxygen in the blood were markedly decreased, and that the proportion of sugar and of urea in the blood was notably increased (*Comptes-Rendus Soc. Biol.*, v. 546; *Comptes-Rendus de l'Acad.*, xcix. 86).

In the face of so much contradiction it is perhaps wisest to reserve opinion, but it does seem as though the present evidences warranted the conclusion reached by E. Perisot (*Thesis*, Paris, 1890) that the action of caffeine upon urea elimination and upon protoplasmic change is inconstant, and not direct and pronounced. It is true that in a long series of very elaborate calorimetrical experiments performed by Professor E. T. Reichert (*New York Med. Journ.*, April, 1890) it seems to have been proven that caffeine increases the heat-production as well as the heat-dissipation, and that of these phenomena, the increase of the heat-production is probably primary. This result is in accord with that of Wilhelm Heerlein (*Inaug. Diss.*, Bonn, 1892), who found marked increase in the consumption of oxygen and formation of carbonic acid produced under the influence of caffeine. Nevertheless, these united results, if their accuracy be accepted, do not show that destructive metamorphosis of nitrogenous tissue is increased by caffeine, but only that there is an increased destruction of carbohydrates.

Elimination.—Richard Schneider (*Ueber der Schicksal des Caffeins*, etc., Dorpat, 1884) found that caffeine, when taken in therapeutic doses, is entirely destroyed in the system, and, when in toxic amount, is partially destroyed and partially eliminated by the kidneys: but it is not at all impossible that it will be eventually found that the unchanged alkaloid escapes through various channels in its entirety.

Summary.—Caffeine is a powerful stimulant to those cells of the cerebral cortex which are functionally connected with consciousness and intellectual action. It is also mildly stimulating to the respiratory centres and probably to the motor cells of the spinal cord, but seems to be without action upon the nerve trunks. It is a powerful muscle poison, at first producing a condition in which there is exaggerated muscular excitability, with a tendency to tetanic contractions upon momentary stimulation, and afterwards a stage of stiffness, weakness,

and, finally, lost excitability. It is a mild stimulant to the circulation; probably by virtue of its relation to the muscle-fibres it increases the cardiac force and perhaps also directly contracts the arterioles. In overdose it depresses the circulation, probably acting both upon the heart and the blood-vessels. It is absorbed with rapidity, and is, at least in part, eliminated through the kidneys, upon whose secreting structure it exerts a marked stimulating influence. Although the evidence is contradictory, it does not at present writing appear probable that caffeine has any distinct specific influence upon protoplasmic nutrition, although it does appear to directly increase the production of carbonic acid and of animal heat.

THERAPEUTICS.—In accordance with its physiological action, caffeine is employed in practical medicine as a cerebral and cardiac stimulant. It is often taken to produce wakefulness and increase the power of labor during excessive work. It is a valuable remedy for the relief of *migraine* and other forms of *nervous headaches*, in which its effects are sometimes marvellous, although more often it fails to accomplish good. To predict in any case what its influence will be, in the present state of our clinical knowledge, is impossible; but the remedy may always be tried in safety in the dose of five grains, taken when the paroxysm is coming on, and repeated in half the quantity once in forty minutes if necessary. In *opium-poisoning*, either in the form of unlimited quantities of a strong decoction of coffee or of the alkaloid itself, it is a standard remedy, but, so far as I know, Dr. J. Hughes Bennett (*Brit. Med. Journ.*, 1874, p. 697) has made the only attempt to establish by exact experiments the asserted antagonism of caffeine and opium. That observer found that the exhibition of from four to four and a half grains of caffeine would save a proportion of cats poisoned with the previously-ascertained minimum lethal dose ($1\frac{1}{2}$ gr.) of morphine. Several of the cats which had thus been saved succumbed some days afterwards to one and seven-eighths grains of morphine. The caffeine was powerless to save animals to which larger doses of the narcotic had been given; so that it is fair to conclude that caffeine is within narrow limits antagonistic to the narcotic alkaloid.

I have had no experience with the use of caffeine as a general stimulant in *acute adynamia*, but various French authors recommend the remedy very highly, and Dr. H. Huchard (*Bull. Soc. Méd. Hôp.*, Paris, 1890) especially commends it in *typhoid fever*, claiming that it relieves not only the adynamia, but also acts as an antipyretic, and through its diuretic influence is especially useful when the urine is scanty and albuminous.

Caffeine is very valuable as a cardiac stimulant in the treatment of all forms of heart-failure. When given to healthy men it decreases the rate and markedly increases the force of the pulse. The original statement of Professor Gubler (*Bulletin Therap.*, xxi. 523) that it acts as a powerful diuretic is also undoubtedly correct. The indications for its

employment are precisely those which call for the use of digitalis. It differs, however, from that drug in the promptness and fugaciousness of its action, and in being a more certain diuretic. It is, therefore, especially useful when there are pronounced dropsical symptoms. In *chronic Bright's disease* it is often of service, especially in the latter stages, when there is marked cardiac failure. In acute Bright's disease it should be employed with caution, if at all. It is superior to digitalis in never disagreeing with the stomach and in having no distinct cumulative tendency. In some cases, however, it produces obstinate wakefulness, and I have occasionally found it necessary to give it solely in the early part of the day. It is usually best to commence with a dose of four grains, given twice daily, increased if necessary to twenty or twenty-five grains a day. For internal administration the so-called citrate of caffeine, which is officinal in the British Pharmacopoeia, is superior to the alkaloid itself, as more soluble. When great promptness of action is required, as in cases of sudden collapse or of sudden cardiac failure, the hypodermic use of caffeine suggests itself. Unfortunately, the ordinary salts are decomposed in the presence of water, and are, therefore, ineligible for hypodermic use. The double benzoate of sodium and caffeine has been proposed as moderately stable and free from irritating properties. One equivalent of salicylate of sodium (160) will also cause the solution of one equivalent of caffeine (244), and the following formula has been commended by M. Tanret for hypodermic use: Salicylate of sodium, 31 parts; caffeine, 40 parts, distilled water, 60 parts.

TOXICOLOGY.—The only case of poisoning by caffeine I have met with is reported by Dr. C. H. F. Routh (*London Lancet*, 1883, i. 680). An adult took a drachm of the pure citrate. The symptoms developed at once; they were burning in the throat, giddiness, faintness, nausea, numbness and tremors of the extremities, pain in the stomach and bowels, profuse diuresis, and finally collapse, with great cardiac oppression and icy extremities. Consciousness was not impaired, and there was no headache until the patient began to recover. In a case reported by Dr. Curschmann (*Deutsche Klinik*, 1873, 377), a woman, in order to produce an abortion, took a decoction made from about eight ounces of freshly-roasted coffee. Two hours later she was found in a condition of great anxiety, with a sensation of intense need for air; she was exceedingly restless, and continually attempted to get up from her chair, but was powerless to do so. All the extremities, but especially the hands, were affected with very pronounced choreic tremors. She knew persons and her surroundings, but her cerebration was very much affected, and the next day she remembered nothing that had happened at this time. The respiration was quick, twenty-four and twenty-five per minute, and short; the pulse one hundred and twelve; the heart-beats very strong, even violent. One hour after the ingestion of the dose violent diarrhoea set in, and continued until the next day. The passages were very thin

and watery, with but little violent pain, but much tenesmus. There was also marked tenesmus of the bladder. The urine was greatly increased in quantity, with the specific gravity of 1014.

CONVALLARIA. U.S.

In 1859, G. F. Walz discovered in the *lily of the valley* (*Convallaria majalis*, the rhizome and roots of which are officinal) two active substances, *Convallarin* and *Convallamarin*. Of these, the first is crystalline, insoluble in water, and, according to Dr. W. Marmé (*Schmidt's Jahrb.*, Bd. cxxxiv. S. 166), when taken in doses of three or four grains, acts as a simple purgative. The glucoside convallamarin is soluble in water, and is the principle to which the plant owes its action upon the circulation. Marmé found that it kills by a direct action upon the heart, and in moderate doses first slows and then quickens the pulse: previous division of the vagi did not interfere with the development of these phenomena. The chief studies upon the physiological and therapeutic action of the lily of the valley are those of Professor Germain Sée (*Bull. de l'Acad. de Méd.*, No. 27, 1882, p. 787) and of S. Isaew (*Hoffmann und Schwalbe's Jahrb.*, 1883, 122, from the Russian). Professor Sée finds that in the dog it first slows the action of the heart and increases the blood-pressure decidedly, the respirations at the same time becoming fuller and a little less frequent. If a toxic dose has been given, the heart's beats become very rapid and irregular, the arterial pressure still being much above normal; finally the pressure begins to fall, the cardiac pulsations to grow more feeble, and death occurs through syncope. It is stated that the pneumogastric nerves are weakened, but never paralyzed, while the general nervous system is not affected. In man the action of the drug upon the circulation is as in the lower animals, and there is said to be usually produced profuse diuresis and sometimes purging. In Isaew's experiments upon frogs with convallamarin, the heart was arrested in ventricular systole by two milligrammes of the pure convallamarin, the frog continuing to live for a long time, the remedy seemingly having no effect upon its general nervous or muscular system: isolating the heart had no effect upon the action of the poison. In the dog the phenomena of convallamarin-poisoning were as described by Professor Sée, it being further noted that the pneumogastrics were not affected, that the pulse was often dicrotic during the stage of rapid cardiac action, and that the final arrest was diastolic, the heart-muscle not being able to respond to the most powerful galvanic stimulation. Dr. I. Ott has found that the cardiac arrest in the dog is systolic (*Archives of Med.*, Feb. 1893). In Drs. Coze and Simon's experiments the frog's heart was rendered slow and extraordinarily full in its beat and finally arrested in systole (*Bull. Gén. Thérap.*, cv. 494). G. Leubuscher (*Zeitschr. f. Klin. Med.*, vii. 582) finds that convallamarin produces in the frog progressive palsy, with cramp-like tremblings and

death from systolic cardiac arrest; in the mammal, violent convulsions and death from diastolic heart-arrest; that it slows the heart-beat in the mammal, and causes arrhythmical contractions, but in no dose elevates at any time the arterial pressure. The evidence seems to be so contradictory as to suggest that different observers have used different principles under the one name. The difficulties of the subject are rather increased than diminished by the recent researches of Leo Löwenthal (*Thesis*, Würzburg, 1883), who, using the same preparation in exactly the same manner and dose upon different frogs of the same species, obtained diverse results which he himself was at a loss to explain. The Russian J. Nathanson (*Lond. Med. Rec.*, July 15, 1887) claims that the confusion is largely due to the impurity and lack of genuineness in the products used, even M. Morck himself having admitted that his commercial convallamarin is not the pure principle. Nathanson found that convallarin produced in man when given in doses of 0.06 to 0.12 gramme three or four times daily only nausea, diarrhoea, and gastric pain; while convallamarin administered in daily amounts gradually increasing from 0.03 to 0.3 gramme reduced the rate of the pulse and markedly increased the flow of urine, only in very rare cases causing nausea or vomiting.

The lily of the valley is said to have been long used by the Russian peasantry for the relief of dropsy, and in 1880 Drs. Troitzky and Bojojawlewsky called attention to it as a valuable remedy in *cardiac valvular disease*, especially when associated with dropsy (*Vratsch*, 1880, 47). Professor Sée recommends it in *palpitation of the heart*, in *cardiac dilatation*, *fatty degeneration*, and other forms of cardiac weakness, also in *valvular lesions* with failing heart-power; in a word, in the class of cases in which *digitalis* is now used. When there is dropsy, its very positive diuretic action renders it especially valuable, and in some cases it purges freely, probably through the convallarin. The value of the remedy has been confirmed by Professor H. Desplats (*Journ. des Sciences Méd. de Lille*, Oct. 1882), and by several other practitioners. Although condemned after trial by Dr. B. Stiller (*Wien. Med. Wochenschrift*, Nov. 1882), by Pel (*Centralbl. f. Therapie*, 1883), by Leyden (*Deutsch. Med. Wochenschr.*, Feb. 1883), by Jacobi and Lubilinski (*Sitzungsb. der Vereins für innere Med.*, 1883), and by G. Leubuscher, it has been highly praised by Professor Silvestrini (*La France Méd.*, October, 1883) and by E. Maragliana (*Centralbl. f. Med. Wissens.*, 1883, p. 43). Dr. E. Sansom (*Lond. Lancet*, vol. i., 1886) gives as the result of his experience that convallamarin is very useful in mitral stenosis with failing of the heart. Dr. Marmé found that the fatal dose of convallamarin was, for the dog, 0.015–0.03 gramme; for the cat, 0.005 gramme; for the rabbit, 0.006–0.008 gramme. Professor Sée gives, of an aqueous extract of the whole plant, from fifteen to twenty-three grains a day; Bojojawlewsky, each day an infusion representing from fifty to one hundred grains of the plant. The U.S. Pharmacopæia

recognizes only a *fluid extract* (*Extractum Convallariæ Fluidum*), the dose of which is from five to fifteen minims. The results obtained by Nathanson (see page 412) show that great caution must be exercised in the practical use of the active principles of convallaria.

STROPHANTHUS.

Under the names of Kombé, Inée, Onaye, Pahonius poison, there have reached Europe various African arrow-poisons, which are now believed to be derived from one or more species of the tropical genus *Strophanthus*,—apocynaceous climbing shrubs. The name of *Strophanthus* Kombé was given by Sir John Kirk to the tree which he first identified as the source of the Kombé poison; but botanists are at present agreed that the species is the *Strophanthus hispidus* of De C. Langgaard states that there are eighteen species of the genus, and that the pods of at least two have entered commerce. The seeds within the pod are abundantly provided with very long, deciduous hairs, which are apt to be shed within the pod itself, and are so numerous as to weigh nearly as much as the seeds. They contain an intensely bitter crystalline principle, *strophanthin*, which is partly soluble in water, and has been shown by Professor T. R. Fraser to be a glucoside, convertible by sulphuric acid into glucose and crystalline *strophanthidin*.

PHYSIOLOGICAL ACTION.—In the healthy man *strophanthus* in sufficient dose produces fall in the rate of the pulse, with increase of force, without alteration of the respiration, but if the dose has been large enough, with some gastric irritation and, according to Professor Drascho, a slight fall in temperature. In Professor Drascho's experiments the hypodermic injection of fifteen drops of the tincture induced violent local irritation, repeated vomiting with nausea, pronounced diuresis, and a fall of the pulse. Twenty drops given by the mouth decreased the pulse thirty beats.

In the lower animals *strophanthus* produces symptoms similar to those that it causes in man, the diarrhoea often being especially violent. No cases of human poisoning have been reported, but after fatal poisoning in the lower animals, evidences of irritation in the gastrointestinal tract are usually present, and violent irritation and even inflammation of the secreting structure of the kidneys, with small hemorrhages, has been noted by several observers. Mairat and Combemale also state that the blood-globules are frequently altered, and the urine, before death, albuminous. The absence of nervous symptoms until very late in the poisoning shows how very little influence *strophanthus* has upon the nervous centres. An observation upon the lower animals made by Mayeur (Lille, *Thesis*, 1883) and by Lemoine, is of great practical interest, especially since similar results have been noted by some of the German authorities in man. These observers found that the *strophanthus* has the tendency to accumulate in the normal system,

so that when small doses are given daily for a length of time, after a time violent and even fatal poisoning results.

The first to make elaborate experiments with strophanthus was Professor T. R. Fraser (*Journ. Anat. and Phys.*, vol. vii. p. 141; also *Brit. Med. Journ.*, ii., 1885).^{*} One-twentieth of a grain of the extract of the seeds produced in the frog stiffness of the limbs, gradual loss of reflex sensibility, and after a time complete loss of voluntary movement, the respiration continuing for a length of time after the cessation of the heart's beat. When the poison is brought in direct contact with the muscles, its influence is immediate, and when, in Fraser's experiments, the muscles of a leg were protected from the poisoning by tying the arteries, galvanization of the nerve caused active contractions at a time when muscles elsewhere failed to respond to any irritation of their nerves or substance. The first influence of the poison upon the muscular fibre is to increase its tonicity, and when the muscle dies it does not go into relaxation, but passes directly from life into post-mortem rigidity.

The confirmation of the work of Professor Fraser by recent observers proves that strophanthus and strophanthin are violent muscle-poisons. The paralysis of voluntary movement and of respiration, as asserted by Bahadburji, is in all probability due to the action of the poison upon the muscles. Death probably sometimes occurs through respiratory arrest, but usually through the heart, since Langgaard is in accord with Fraser as to the cause of death; but Mairat and Combemale declare they have seen a primary respiratory arrest. Moreover, according to the last-named observers, the respiration, which is at first hurried, is usually distinctly slowed before the fatal termination. Bahadburji states that the paralysis is preceded by a stage of hyperæsthesia, but has not been confirmed, that I know of, in this, or in his further assertion in opposition to Fraser, that the motor-nerve trunks are affected. M. E. Gley states that a solution of one part in a thousand of strophanthin causes in the rabbit's eye not only pronounced myosis, but a very rapid and durable anæsthesia. If this be correct, strophanthin must be a sensory nerve paralyzant, at least when locally applied.

Circulation.—Dr. Fraser proved that strophanthin has a direct action upon the heart of the frog, and in this has been confirmed by Bahadburji, by Huchard, by Reusing, by Gley and Lapicque, and other observers. By minute doses the rate of the beat is lessened, and the size and force of the aortic pulse-wave increased. Reusing found strophanthin to be about twenty times as strong in its influence upon the isolated heart as was digitalin, and also more permanent in its effects, as the heart arrested by digitalis could be restored by washing out with fresh serum,

^{*} It has since been physiologically studied by K. N. Bahadburji (*Brit. Med. Journ.*, ii., 1887), G. Lemnise (*Compt.-Rend. Soc. Biol.*, v., 1888), Gley and Lapicque (*Ibid.*, 1887), Mairat, Combemale, and Groquler (*Ibid.*, iv., 1887), Laborie, also Gley (*Ibid.*, 1889), Langgaard (*Berlin. Klin. Wochens.*, xxv., 1888), Paschke and Zerner (*Med. Jahrb. Wien.*, 1887), Pöpper (*Centraltb. f. Med. Wissensch.*, xxvi., 1888), Henri Huchard (*Paris Thèse*, 1888).

a process which had no influence when the cardiac arrest was due to strophanthin. It is noteworthy that Fraser and some other investigators have found that the frog's heart is arrested in systole, whilst Reusing and Huchard have seen it stop in diastole, and Paul Bert has noted in the cat both systolic and diastolic arrest. The muscle of the frog's heart, according to Fraser, is much more susceptible to the influence of strophanthin than the voluntary muscles, and passes rapidly into post-mortem rigidity, with acid reaction.

The combined testimony of Fraser, of Popper, of Gley, of Paschkis and Zerner, of Langgaard, and other investigators, proves that moderate doses of strophanthus cause in mammals pronounced rise in the arterial pressure. As this occurs as well in curarized (Gley) as in normal animals, it must be due to a direct action of the drug, and not secondary to changes in the respiration; after poisonous doses the pressure immediately or secondarily falls gradually to zero.

The sphygmographic work of Paschkis and Zerner show that the strophanthus influences the blood-pressure in man as it does in the lower animals. The cause of the rise of the blood-pressure is not fully made out. It certainly is in part due to the direct stimulating influences of the drug upon the heart itself, but we do not know how far the vessels are affected. Bahadurji asserts that they seem to be contracted under the influence of the drug. Popper found that section of the splanchnic nerve of the cervical spinal cord does not prevent the rise of the arterial pressure, so that if the vessels are affected it is probably by a direct action upon their muscular cords. In Popper's experiments the pressure in the pulmonary artery rose much less than that in the aorta, and the pressure in the veins was very little altered. The slowing of the pulse is probably due to the direct action of the drug upon the heart, Paschkis and Zerner* having found that in the dog it is not prevented by previous section of the vagus; Popper states that in the advanced poisoning there is peripheral paralysis of the vagus without alteration of the irritability of the accelerator nerves. The immediate cause of the fall of pressure is not known; it may well be excessive systole.

Diuretic Action.—Although several observers have failed to notice an increase in the urinary secretion in man and in animals under the influence of strophanthus, yet the general testimony is too strong to be gainsaid; and it seems established that strophanthus acts, not only in cases of cardiac disease, but also in healthy men and animals, as a powerful diuretic. This indicates that the drug has a direct stimulating influence upon the secreting structure of the kidneys, a conclusion which is confirmed by the renal lesions of the poisoning, and also by the oncometric experiments of Dr. Phillips, who found the size of the kidneys not affected by the drug,—i.e., that it produced no pronounced congestion of the kidneys.

* These observers state that sometimes in the normal dog the slow pulse was wanting.

Summary.—Strophanthus is primarily a musculo-poison, which, unless locally applied, probably has little or no influence upon the nerve-centres or the nerve-trunks; which, further, has relations not only with the voluntary and the cardiac muscles, but probably also with the muscular fibres in the walls of the vessels. It is locally irritating and stimulating to the gastro-intestinal mucous membrane, and even to a greater degree to the secreting structure of the kidneys. The active principle probably escapes with the urine.

THERAPEUTICS.—Strophanthus has been employed by a sufficient number of careful clinical observers to prove its value in practical medicine. The indications for its administration are precisely similar to those which call for the use of digitalis. In cases of *cardiac weakness* a single dose usually produces in from half an hour to an hour a fall in the frequency of the pulse with a distinct increase of force, effects which last from four to eight hours. The general testimony is that it is quicker and less enduring, but less certain, in its action than is digitalis. It would seem to be especially indicated in *acute collapse*, but the tincture is too irritant for hypodermic use, and I have no knowledge of the use of strophanthin. As a diuretic, both in health and disease, strophanthus seems to be superior to digitalis, and will probably be found of especial value in cases of *pulmonic oedema* or of severe *general dropsy* due to cardiac disease. When given in overdose it produces burning in the oesophagus and the stomach, with gastric distress and severe vomiting. It is not likely to replace digitalis in heart-disease, but will rather be used as a succedaneum when a very immediate, temporary effect or a temporary change of remedies is required. M. Furbringer reports three cases in which, after the remedy had been used in a large quantity and for a long time, sudden death from syncope occurred (*Le Bull. Méd.*, Jan. 22, 1888). It may well be that the death was directly caused by the strophanthus, but it is more probably a parallel occurrence to what often happens in advanced cardiac disease treated with very large doses of digitalis (see page 398). Zerner and Loaw (*Wien. Med. Wochens.*, 1887) have employed strophanthus with alleged success in *Basedow's disease* and in *Bright's disease*, and they consider it especially useful in renal affections with secondary failure of the heart, a condition in which I have seen it act most advantageously. Rothziegel and Koralzowski (*Wien. Med. Bl.*, xi., 1888) and Dr. H. Haas (*Deutsch. Arch. Klin. Med.*, xliii., 1888) commend it highly, not only in chronic but also in *acute Bright's disease*.

The *tincture* (*Tinctura Strophanthi*—5 per cent., U.S.) may be given in doses of from five to ten drops. To maintain the effect of the drug it is necessary to give it at least every eight hours. Professor Fraser found that a solution of one part of strophanthin and six million parts of water would cause systolic cardiac arrest in the frog in about twenty minutes, and Professor Drasche has used it in doses of one milligramme three times a day; but the purity of this strophanthin

is doubtful. Rothziegel and Koralzewski state that strophanthin acts perceptibly in five or ten minutes, and is superior to the tincture of strophanthus in being more certain and much less apt to cause disturbance to the stomach. They give the dose as 0.0002 to 0.0003 gramme, and have in some cases administered as much as 0.005 gramme during twenty-four hours. Until the dose is more accurately determined, strophanthin should be used with great caution.

SPARTEINE.

Sparteine is a liquid alkaloid obtained from the *Cytisus Scoparius*, or common broom plant. (See SCOPARIUS.) It is colorless, of a penetrating odor and extremely bitter taste, soluble in alcohol, in ether, and in chloroform. *Sparteine sulphate* (SPARTEINÆ SULPHAS, U.S.) occurs in colorless prismatic crystals or granular powder, freely soluble in water and in alcohol, having a neutral reaction and a bitter, slightly saline taste.*

PHYSIOLOGICAL ACTION.—According to Husemann (*Pflanzenstoffe*), Mitchell found about four grains of sparteine administered to the rabbit to cause a very short stage of excitation, followed by quiet sleep and death in three hours, while in Schroff's experiments a single drop produced violent convulsions followed by muscular weakness, depression of the heart's action, renewed convulsions, and death. The more recent researches of De Rymon, Griffé, and others show that there are two stages of sparteine-poisoning: the first of these is characterized by trembling, incoördination of movements, increase of reflexes, clonic and tonic convulsions, embarrassment of respiration, acceleration of the pulse, and enfeeblement of the heart; the second, by enfeeblement of all the functions, the respiration becoming more and more depressed, and death preceded by convulsions occurring from paralysis of the respiratory centres. Dr. Fick found that by artificial respiration life may be prolonged for a very considerable period. Fick (*Arch. f. Exper. Path. und Pharm.*, 1887) is in accord with Mitchell in stating that sparteine affects the cerebrum both of frogs and of mammals, and that it is therefore a narcotic, although its paralyzing influence upon the spinal cord and upon the motor nerves is dominant. This alleged influence upon the motor nerve-trunks appears, however, to be disproved by De Rymon (*Thèses*, 1880) and by Griffé (*Thèse*, Lyons, 1886), and by V. Gluzinski (*Deutsch. Archiv Klin. Med.*, 1884, xliv.), who are in accord in affirming that neither the motor nor the sensory nerves are affected by the alkaloid. Fick and Gluzinski, with other observers, agree that the loss of reflex activity and the fatal arrest of respiration are of centric origin;

* *Oxysparteine*.—This alkaloid, which occurs in white, hygroscopic crystals, soluble in water, alcohol, ether, and chloroform, is made by the oxidation of sparteine (*Ber. d. Deutsch. Chem. Ges. Jahrg.*, xxiv.). Dr. K. Hürthle (*Archiv f. Exper. Path. u. Pharm.*, 30, 1892), as the result of a series of experiments upon the lower animals, concludes that it increases the work of the heart without affecting the tone of the vessels.

but according to Gluzinski the spinal depression is preceded by a stage of excitement. When applied locally to the muscles, sparteine has some influence in diminishing their excitability and prolonging the duration of the latent period (Do Rymon, Griffe, Gluzinski). But it does not destroy the functional activity of the muscles even when brought in direct contact with them in a concentrated form, and its muscular influence is too feeble to be manifested in general poisoning.

Dr. Laborde (*Compt.-Rend. Soc. Biolog.*, Nov. 21, 1885) was the first to call attention to the fact that sparteine acts upon the heart, causing both in the frog and in the mammal an enormous increase in the size and height of the pulse-wave. The subject has been further investigated by Griffe (*Thèse* 224, Nancy, 1886), by Garand (*Thèse* 218, 1886, Lyons), by Masius (*Bull. Acad. Roy. Méd. Belg.*, vol. i. p. 218), and by Gluzinski (*Vratch*, No. 3, 1887, abstract in *Med. and Surg. Reporter*, July, 1887). According to Griffe, in the isolated heart of the frog sparteine causes an extraordinary persistence of contractions; if the dose has been moderate there is an acceleration of the pulse from paralysis of the pneumogastric centre, followed by a slowing of the heart; if the dose has been very large the pulse is rendered less infrequent from the beginning. The same investigator found that in mammals small doses accelerate the pulse without altering the arterial pressure, and that somewhat larger doses cause at first acceleration and then retardation of the pulse. After very large doses there is a primary slowing of the pulse, with a gradual fall of the arterial pressure in spite of the fact that the cardiac waves are extremely large and full. Masius in experiments upon the dog obtained results similar to those of Griffe, and calls especial attention to the fact that in poisoning during the period of asphyxia the pulse-waves are extraordinarily large. Fick, Griffe, Garand, and Masius all note that small doses of sparteine weaken, and larger doses paralyze the peripheral portions of the pneumogastric nerves. Rather discordant with these various results are those reached by Gluzinski, who states that three stages of the action of sparteine upon the heart of mammals are easily made out. *First*, in which there is a slowing of the pulse due to excitement of the vagi nerve; *second*, in which the pulse is only slightly slowed, or sometimes is even increased in frequency, the change being due to paralysis of the pneumogastric and inhibitory ganglia of the heart; *third*, with slow pulse, due to the direct action of the sparteine upon the heart muscle. It is evident that if the drug acts in the manner made out by Gluzinski, the apparent effects must vary according as one or more of the cardiac actions of the drug appears to triumph: so that the phenomena noted by Gluzinski are not absolutely contradictory to those of the older observers. It is worthy of note, also, that Fick affirms that the inhibitory centres in the heart are paralyzed. According to Fick, muscarine has little or no effect upon the heart under the influence of sparteine.

According to Legris, sparteine in doses of twenty-five centigrammes

has no perceptible influence upon the human brain or spinal cord, although doses of thirty centigrammes or over cause vertigo, headache, palpitations, and formications in the extremities. After forty centigrammes Garand noticed very decided cardiac pain, with sensations of heat and redness of the face, and loss of power in the legs,—these symptoms commencing about twenty minutes after the ingestion of the alkaloid and reaching their maximum in four or five hours.

It is still doubtful whether sparteine does or does not fully represent the diuretic influence of scoparius. Griffe affirms that in his experiments upon rabbits it produced absolute decrease in the excretion of urine, and although some clinicians assert that it acts in man as a distinct diuretic, others claim that any increased diuresis is secondary to the regulation of the circulation.

Summary.—Our present knowledge is very imperfect, but such facts as we have indicate that sparteine acts powerfully upon the cerebral and spinal centres as a depressant; that it kills by paralyzing the respiratory centre; that it has a direct influence upon the heart or its contained ganglia, by virtue of which at first it increases the force of the contraction, but, if the dose have been large enough, finally lessens the force; that it may first slow the pulse by stimulating the pneumogastric nerves (Gluzinski), but that it soon increases the pulse-rate by paralyzing inhibition, and afterwards diminishes it by acting upon the heart itself; and that its direct effect upon the kidneys is uncertain.

THERAPEUTICS.—The results obtained in the physiological laboratory indicate that sparteine is a direct stimulant to the heart, but has no effect, at least in therapeutic doses, upon the vaso-motor system. The use of sparteine in diseases of the heart has been studied by a number of clinicians; notably by Professor Sée, by Garand, by Roland (*Le Poitou Méd.*, 1887), by Voit (*Med. Chron.*, April, 1887), by J. M. Clarke (*Amer. Journ. Med. Sci.*, 1887), by Kurloff (*Deutsch. Archiv f. Klin. Med.*, xlv., 1889), and by Pawinski (*Gaz. Hebdom. de Med.*, Paris, 1888), who are all in accord in affirming it to be of value in the treatment of cardiac affections, in which it slows the pulse and renders it more regular, increases diuresis, and is superior to most other cardiac remedies in its power of controlling general nervous excitement. Pawinski states that in pure nervous palpitation it exceeds digitalis in power and certainly in action, and that it is a valuable sedative in hysteria, neurasthenia, and allied conditions. Both Pawinski and Sée claim that it has a remarkable power of regulating the heart's action; the latter observer indeed affirms that no known remedy equals it for the purpose of making an irregular pulse regular. On the other hand, Pawinski warns against its use in cases in which the heart muscle is believed to have undergone degeneration. Its action is a rapid one, the symptoms produced by it, according to Clarke, Sée, and others, developing in thirty minutes to an hour after its ingestion, and continuing for five or six hours. According to Clarke, these symptoms consist primarily of a marked retardation of the pulse,

with increase of the force and of the arterial tension, the skin at the same time becoming red and moist, while the respiration, which is at first quickened, soon becomes slower and fuller than normal. In overdoses it is said to cause very high tension of the pulse, with sharp, cutting or throbbing pains in the cardiac region, and sometimes with nausea. It has been employed with asserted excellent results in all forms of *valvular disease*, in *asthma*, and especially in *functional cardiac derangements*. The very important statement made by Clarke, that it will control the pulse-rate and general symptoms in *Graves's disease*, receives some confirmation in the work of Pawinski and in my own experience. Some clinicians, notably Hans Leo (*Zeitschr. f. Klin. Med.*, 1887) and Hiero Stoessel (*Centralb. f. Therapie*, 1887), have found sparteine, however, a very uncertain remedy. I do not believe that for general purposes it equals digitalis, but it probably has a distinct field of usefulness as a succedaneum to that drug, and even as a substitute in neurotic cases. Pawinski gives 0.016 to 0.04 gramme three times a day, increasing gradually to 0.6 gramme during the twenty-four hours. The officinal *sulphate* may be used in pill or solution in commencing dose of from one-quarter to one-half a grain, cautiously increased to two grains if required, and repeated every six to eight hours.

ADONIDIN.

Adonis vernalis, a plant of Northern Europe and Asia, contains a glucoside to which Dr. Cervello has given the name of *adonidin*. According to Cervello, adonidine causes in the frog first increase in the force of the systolic contractions, then irregularity of rhythm with long diastolic pauses, and finally arrest in violent systole, the most characteristic phenomenon being the peristaltic movements which precede the cardiac arrest. According to Dr. H. A. Hare (*Therap. Gaz.*, 1886, 220), adonidine first increases and then slows the rate of the beat in the cut-out frog's heart, while its injection into the frog is followed by a period of slowing of the cardiac movements, with long diastolic pauses, succeeded by great increase of the pulse-rate, which in turn gives way to slow movement, ending in arrest. Whether the heart be isolated or *in situ*, this arrest is diastolic. Although Cervello and also Guirlet (*Nancy, Thesis*, 1888) state that the heart is arrested in systole, Dr. Hare affirms that, whether the heart be isolated or *in situ*, the arrest is diastolic. The contradiction is not easily explained, unless it be through the observation of Guirlet, that in the rabbit he has seen the left ventricle in permanent systolic contraction, with the other cavities dilated and full of blood. The slowing of the pulse noted by Dr. Hare was found by him to be due to stimulation of the pneumogastrics, as it was prevented by their section. That the diastolic arrest was not an occasional phenomenon the result of excessive inhibition, as is sometimes seen from digitalis, was proved by its occurring after section of the vagi, as well as by the fact that galvanization of these nerves in the later stages of

the poisoning failed to inhibit the heart, the nerves appearing to be paralyzed.

In Dr. Hare's experiments adonidin increased very distinctly the arterial pressure in the dog, while decreasing the pulse-rate. After large doses the first rise is followed by a marked fall of arterial pressure, with irregularity of the heart's action, and finally diastolic arrest. The experiments of Cervello (*Arch. f. Exp. Path. u. Pharm.*, xv.) and of Bubnow (*St. Petersb. Med. Woch.*, 1879) are in accord with those of Dr. Hare in showing that the drug produces first rise and then fall of pressure. Dr. Hare found that in animals whose spinal cord had been previously cut, a rise of pressure followed the exhibition of adonidin, but was not so great as in the normal dog, so that it is possible that the drug acts as a stimulant not only on the heart but also on the vaso-motor system. The first slowing of the pulse, according to Dr. Hare, is the result of stimulation of the inhibitory nerves, since it was prevented by their previous section, while the final fall of pressure is at least in part due to the vaso-motor palsy, since neither galvanization of the sciatic nerve nor asphyxia had any effect at a time when the heart had still considerable power.

THERAPEUTICS.—In 1879 *Adonis vernalis* was introduced to the medical world as a cardiac stimulant by Bubnow, a pupil of Professor Botkin. Since then it has been tested by a number of physicians, with fairly concordant results. The general testimony is that its action in disease resembles that of *digitalis*, and that it is useful in the same class of cases. It is much more prompt than is *digitalis*, and Durand affirms that it has no cumulative tendency. There has been some difference of opinion in regard to its diuretic action, and whatever of such influence it has must be attributed to its action upon the circulation in the kidneys, rather than to any marked direct power over the secreting structure. Durand asserts that it never produces disturbances of the alimentary canal, but Lublinski and Huchard have both seen it produce so much vomiting or diarrhoea as to require its withdrawal. In a case reported by Durand in which by mistake three grains of adonidin were given every half-hour, violent vomiting and diarrhoea were the most troublesome symptoms. Bubnow employed the infusion made from the whole herb 4 to 8 parts in 180 parts of water, and of this he administered a tablespoonful every two hours. Durand gives the dose of adonidin as 0.02 centigramme (0.3 grain) every three or four hours.

FAMILY II.—CARDIAC DEPRESSANTS.

THERE are certain drugs which are used by practitioners to decrease the activity of the circulation; and it is these which are here considered under the heading of *Cardiac Depressants*. Many, in fact all of them, possess other powers besides those which cause them to be considered under this caption, and none of them are in very close accord in these qualities. There is, however, a *general* resemblance in the action of such as are derived from the vegetable kingdom, in that they are all depressants to the motor nervous system and yet all produce convulsions. I have made an especial experimental study of these convulsions (*Phila. Med. Times*, vol. iii.), and have found that they are cerebral and not spinal, because they do not occur in any part of the body separated by section of the cord from cerebral influence. Further, they are probably due to disturbance of the circulation at the base of the brain, for the following reasons, the truth of each of which has been experimentally determined: first, lessening of the circulation at the base of the brain will cause convulsions; secondly, the convulsions produced by the cardiac depressants do not occur until the arterial pressure is reduced about one-half; thirdly, if the disturbance of the cerebral circulation be artificially increased by tying the carotids previous to poisoning, or in any other way, the convulsions come on sooner and are more violent; fourthly, in some animals the convulsions caused by arresting circulation at the base of the brain are feeble and ill defined, while in others they are violent, and I have found that in species of the first order cardiac depressants produce but slight convulsions, while in species of the second order they cause violent convulsions.

The indications for the use of a cardiac depressant may be said to be increased arterial excitement, sthenic fevers, and severe local inflammations. In order that a rational selection of the various drugs may be made for any individual case, it is necessary to study how, in these various conditions, relief is afforded by an arterial sedative. When there is arterial excitement from irritation or excitement of the heart, the mode of relief is too obvious to need discussion. It is plain that in such a case a drug should be selected which simply depresses the heart's action and does nothing more. In sthenic fever the case is different: here it is desirable to relax the peripheral vessels and to promote a flow of blood to them, while the rapidity and force of the circulation are diminished. A drug which depresses the action not only of

the heart but also of the superficial vaso-motor nerves is here indicated, and if to these powers is added a special one of stimulating the perspiratory glands, the most perfect remedy is obtained. With inflammation the effect desired is a lessening of the flow of blood to the part. A simple cardiac depressant may do this, by lowering the force of the circulation, but a cardiac vaso-motor depressant is far more powerful. The blood-vessels of the inflamed part are already dilated, and consequently attract blood, as it were, to the part. If the remedy dilates all the blood-vessels, this local attraction ceases, and blood is diverted from the inflamed tissue. It would appear from the experiments of Ludwig, Schiff, and others (*La Nazione*, Aug. 1872) that the blood-vessels, after complete dilatation, are able to hold twice the normal amount of blood, and Golz, quoted by Fothergill (*Brit. Med. Journ.*, 1873), found that the intestinal vessels were able to contain all the blood of the body. These facts show how by means of an arterial sedative, which paralyzes the vaso-motor centres, "we can bleed a man into his own blood-vessels," or, in other words, get much of the effect of a venesection by drawing blood from the diseased part.

ANTIMONY.

ANTIMONII OXIDUM—ANTIMONY OXIDE. U.S.

A grayish-white powder, almost insoluble in water, wholly soluble in hydrochloric or tartaric acid and in a boiling solution of potassium bitartrate. It is prepared by dissolving the sulphuret of antimony in hydrochloric acid, adding nitric acid, and precipitating with water of ammonia. Its solution in the stomach is dependent upon the acid there present, and consequently, being uncertain in its action, it should not be used internally—although it is capable of producing all the effects of tartar emetic, for the preparation of which it was introduced into the Pharmacopœia. *Antimoni Sulphidum*, U.S., *Antimoni Sulphidum Purificatum*, U.S., and *Antimonium Sulphuratum*, U.S., are still more uncertain preparations, whose therapeutic use ought not to be encouraged.

ANTIMONII ET POTASSII TARTRAS—ANTIMONY AND POTASSIUM TARTRATE.

TARTAR EMETIC is prepared by boiling the oxide of antimony in a solution of bitartrate of potassium. It occurs in the form of a white powder, the result of the pulverization of transparent, colorless, slightly efflorescent crystals, which are most commonly rhombic octahedrons. Its taste is variously described: to me it is at first very slight, but after a time styptic and acrid. In some persons it blisters the tongue and lips after a few moments of contact. Tartar emetic is insoluble in absolute but soluble in dilute alcohol, soluble in from two to three parts of boiling water, and in seventeen parts of water at 59° F. It is incompatible with alkalis and with acids, including tannic acid and substances containing it.

PHYSIOLOGICAL ACTION.—Locally applied, tartar emetic is an irritant, acting upon some very delicate and susceptible skins in a very short time. In most instances, however, its continuous application for several days is necessary to produce any effect. At first there is simply a redness, accompanied by some burning pain and the eruption of small papules, which shortly become converted into vesicles and then into pustules. These are irregular in shape and size, varying from one-eighth of an inch to an inch and a half in diameter, and are very painful. Sometimes these pustules give rise to small sloughs, but generally, if the application be withdrawn, they simply give origin to superficial ulcers, which readily heal.

The only symptoms which are induced by small therapeutic doses (one-twelfth of a grain) of tartar emetic when exhibited for a short time are a scarcely perceptible diminution of the force of the pulse and an increase of the perspiration.

By somewhat larger amounts of the drug, nausea is induced, accompanied in a more decided degree by the phenomena just mentioned. After large doses, prolonged nausea, violent vomiting and retching, with marked reduction of the force of the pulse, great muscular relaxation, and a feeling of faintness, occur. At the same time the saliva is generally increased in amount, and the skin is bedewed with sweat.

After poisonous doses all these symptoms are intensified. The vomiting is violent, repeated, continuously re-excited by the slightest provocation, and is accompanied by burning in the œsophagus and stomach and by colicky pains in the abdomen. The matters vomited are first mucus, then mucus with bile, and finally, in some cases, blood. With the gastric disturbance occurs violent and frequent serous purging, the discharges resembling those of cholera, but becoming in some cases towards the last bloody. Cramps may occur in the extremities, and, in conjunction with the serous purging, have caused the antimonial poisoning to be mistaken for cholera. The exhaustion is extreme, and deepens into collapse, with thready or imperceptible pulse, pinched, livid countenance, suppressed voice, profuse cold sweats, lowered temperature, and at last death from asthenia, generally preceded by stupor or convulsions: indeed, Taylor reports cases in which wild delirium was present some hours before death. The urine* in mild cases is increased in quantity, as it is also in the beginning even in fatal cases, but in such towards the close it is generally scanty and bloody, and even suppressed. C. Gathgens found, in some incomplete experiments, an increase of the elimination of urea after repeated non-toxic doses of antimony (*Centralbl. f. Med. Wiss.*, 1870, 321).

* What is said in the text is, I think, correct; although authorities differ on this point. Trousseau (*Traité de Thérapeutique*, 4th ed., vol. I. p. 619) affirms that it is suppressed; Huremann, that it never is suppressed (*Toxicologie*, p. 854); Tardieu, that it is scanty. For a case in which it was suppressed, see Taylor's *Medical Jurisprudence*, London, 1873, p. 308.

It is evident that the symptoms just enumerated can be best studied in detail under several heads. Before entering upon this, however, it is well to premise that the experiments of Viborg (*Stille's Therapeutics*, vol. ii.), Buchheim, Courten (*Ibid.*), Magendie (*Ibid.*), Ackermann (*Virchow's Archiv*, Bd. xxv. p. 531), Richardson (*Lancet*, May, 1856), Nöbiling (*Schmidt's Jahrbucher*, Bd. cxl. p. 24), and Radziejewski (*Reichert's Archiv*, 1871), and of others, have demonstrated that tartar emetic acts upon the lower animals precisely as upon man.

Circulation.—When a sufficient dose of tartar emetic is injected into the frog (Radziejewski, Ackermann, Nobiling), the cardiac contractions in a very short time are lessened in frequency and force, and become irregular, the auricles pulsating more frequently than the ventricles, until finally arrest occurs in diastole. After death the irritability of the cardiac muscle to ordinary stimuli is almost, or more frequently entirely, destroyed; but in the recent experiments of I. Soloweitschyk (*Arch. f. Exper. Path. u. Pharm.*, xii. 440), digitalis placed upon the paralyzed heart caused it to recommence its action,—evidence that it is rather the excito-motor ganglia than the musculo-fibre which is affected by the antimony. Upon the heart of the mammal the drug acts as upon that of the frog. According to the researches of Ackermann and of Ernst Sentz (*Diss. Inaug.*, Dorpat, 1853), the arterial pressure always falls steadily and to an extreme degree. The pulse sometimes seems accelerated at first, but in the great majority of cases is decreased very decidedly in its rate. During this period of slow pulse the diastolic pauses are extremely long, but the individual beat will influence the mercurial column of the cardiometer five times as much as normal. After a while the pulse suddenly becomes very rapid, the force of the heart-beat is almost completely lost, the arterial pressure falls to a minimum, and in a very few moments diastolic arrest occurs. It is evident that the action of antimony upon the heart is a direct one. The irritability of the muscle is lost, and Ackermann has found that the cut-out heart of the frog is affected by the solution of tartar emetic; further, the experiments of Radziejewski have proved that the peripheral ends of the vagi in antimonial poisoning are early more or less completely paralyzed, so that the diastolic arrest cannot be due to excitation of the inhibitory apparatus.* The depression of the heart-muscle power does not seem, however, to be the sole cause of the lowering of the blood-pressure, for Soloweitschyk has found that galvanization of the vaso-motor centre with a powerful current is

* Perhaps the present is as fitting as any other place to notice the theory of Nöbiling, that the action of tartar emetic upon the heart is owing to the potash it contains. This theory in itself is so improbable that it would seem scarcely worthy of discussion, were it not for the fact that Nöbiling asserts that the tartrate of antimony and soda is not poisonous. Dr. Radziejewski (*loc. cit.*, p. 495) has repeated and extended the experiments of Nöbiling and completely disproved both the asserted fact and the theory based upon it, showing that the soda-salt is as poisonous as the potash-salt.

powerless to produce any elevation of the arterial pressure at a time when the heart still responds to stimuli. Moreover, the fall of the arterial pressure occurs at a time when the heart is apparently beating with more than its normal force. The conclusion is reached that *antimony lowers arterial pressure by a direct action upon the heart and the vaso-motor system*, and that it is probably the peripheral portions of the latter system which are affected.

Nervous System.—A prominent symptom in antimonial poisoning is paralysis, affecting to an extraordinary degree the sensory and to a less extent the motor system. In man the anaesthesia which occurs in animals has been overlooked, but in the advanced stages of poisoning it is no doubt present. Radziejewski and Soloweitschyk have found that the depression of reflex activity occurs after section of the cord, and is therefore not due to stimulation of the Setschenow inhibitory centre; that it is not prevented by tying an artery and cutting off access of the poison to the nerve, and is therefore not peripheral. It consequently must be spinal; and, as both observers noted that in the frog and the rabbit voluntary movements persist after the total abolition of sensibility and of reflex activity, the conclusion is reached that antimony is a paralyzant to the *receptive centres or sensory tract of the spinal cord*.

Radziejewski states that sensibility is first lost towards thermic and chemical irritants, and then towards tactile stimuli. The motor nerves and muscles are said to retain their functional power.

Temperature.—The influence of antimony upon the temperature appears not to be very marked when the drug is exhibited in ordinary therapeutic doses. Thus, Ackermann found that, after doses severe enough to induce violent vomiting, no alteration in the temperature could be discovered by the thermometer under the tongue. Owing, no doubt, to the disturbance of nervous and arterial action, there is in these cases, however, a very marked reduction of the temperature of the extremities. Thus, in the cases just alluded to (Ackermann) the heat of the hands was lowered from 0.2° C. to 3.5° C. in various persons. This decrease of the temperature is certainly in a measure due to increase of the heat-evolution.

After poisonous doses of antimony the decrease of animal heat is very perceptible, provided the victim live sufficiently long. Thus, in Ackermann's experiments a fall of only 1.6° C. occurred in rabbits killed in the hour, but in those that lived five hours the depression amounted to 6.6° C.

Abdominal Organs.—It cannot be gainsaid that tartar emetic acts as an irritant upon the alimentary mucous membrane. Although cases (*Archives Gén.*, Sept. 1865) have been reported in which no lesion has been found in the stomach or bowels after death from antimony, yet in the great majority of instances very decided indications of violent inflammation have been present.

Dr. Radziejewski, on the strength of this action, and of two experi-

ments in which he found the greater portion of the ingested antimony in the vomit of the patient, has advanced the theory that the emesis is due to a local action of the drug. The persistent nausea, however, certainly indicates that the remedy does not act like the so-called mechanical emetics. Further, the vomiting induced in the experiment of Magendie, of replacing the stomach of an animal by a bladder and giving tartar emetic, would seem at first sight to settle the point completely. This experiment of Magendie has been confirmed by Brinton (*Cyclopædia of Anatomy*, Supplement, p. 319; *Lancet*, 1853, vol. ii. p. 599), who further proved that when tartar emetic was injected into the vein of an animal it was very freely and rapidly eliminated by the stomach. Dr. B. W. Richardson (*Lancet*, vol. i., 1856) has corroborated this, and has also found that a similar elimination follows the inhalation of antimoniated hydrogen. I think, therefore, it must be conceded—first, that the finding of even a large quantity of antimony in the vomit does not prove that its action on the stomach is chiefly a local one; secondly, that the emesis is certainly preceded by at least a partial absorption. This would seem to show that the emesis is purely centric. The experiments of Mooso (*Schmidt's Jahrb.*, clxix. 236), on the other hand, indicate that the local action of the drug is a powerful factor in the production of the vomiting. It was found that when tartar emetic was administered by the mouth vomiting was caused by smaller quantities and more promptly than when injected into the veins; also that, after section of the peripheral vagi in the abdomen, a reverse relation existed between the two methods of administration. If these experiments be, as they appear, correct, tartar emetic must cause vomiting partly by an action on the centres and partly by a local influence upon the stomach. The purging induced by tartar emetic is seemingly an effort at elimination.

Respiratory Organs.—The respiration in poisoning by antimony is very irregular, with all sorts of variations in the rhythm of the act. In the advanced stages the pauses are often very long, and the inspiration and expiration so forced and prolonged that very generally, in animals at least, marginal emphysema and subpleural ecchymoses are found after death. The origin of the respiratory trouble is probably somewhat complex, the chief factor being the direct influence of the drug upon the respiratory nerve-centres, and minor causes the intense venous congestion due to the failure of the circulation, and the alteration of the blood itself. Upon the mucous membrane of the lungs antimony acts directly or indirectly, even in moderate doses, as is shown by clinical experience and by the experiments of Mayerhofer (*Nothnagel's Arzneimittellehre*, Berlin, 1870, p. 219).

Summary.—Tartar emetic is a very powerful depressant to the circulation, acting directly upon the heart-muscle or the contained ganglia, and also widening out the blood-paths by an action upon the vaso-motor system which is probably peripheral. It produces vomiting by an action

which is probably in part centric and in part peripheral. It appears also to be a direct depressant to the respiratory centres, but has little influence upon the nerve-centres in general, though there is reason for believing that the toxic dose does affect the receptive or sensory centres of the spinal cord. It is rapidly absorbed and rapidly eliminated through the mucous membrane of the stomach and of the intestines, and especially through the kidneys. Locally, it is a powerful irritant.

THERAPEUTICS.—There are three indications to meet which tartar emetic is constantly employed. The first of these it fulfils by virtue of its powers as an *emetic*. The discussion of this may be found in the chapter upon Emetics.

The second purpose for which antimony is used is to *depress arterial excitement*. It is chiefly in *inflammation* that tartar emetic is used as an arterial sedative. In combination with more decided diaphoretics it is constantly employed by some surgeons in *fever after operations*, in *gonorrhœa*, and in various *sthenic inflammatory affections*. In *pneumonia* it has been very largely used, forming an essential portion of the older plan of treating that disease. According to the method of Rasori, four or five grains a day were at first given, but rapidly increased to twenty-four or even thirty grains daily. Although by the aid of opiates and careful dilution a species of tolerance was often obtained for these heroic doses, yet very properly the plan has been abandoned by modern therapeutists. As tartar emetic if administered in sufficient quantity to depress markedly the circulation causes generally intense nausea and often purging, I think it is inferior to aconite or veratrum viride when it is desired to depress the circulation very decidedly in *pneumonia* or any other disease.

Owing to its action upon the mucous membrane of the bronchial tubes, in the first stages of *bronchitis* tartar emetic is a valuable remedy. After free secretion has been established, other expectorants are, I think, of more service. The value of antimony as a *diaphoretic* depends largely upon its action on the circulation. Minute doses of it are constantly employed to increase the efficiency of fever-mixtures. It must always be borne in mind that it is a powerful depressant, and is therefore to be employed only in *sthenic cases*.

As a *counter-irritant*, tartar emetic is used only when it is desired to produce a slow, persistent, and at the same time very decided impression. For further discussion of its application to disease, see the chapter on Rubefacients.

TOXICOLOGY.—The symptoms ordinarily produced by poisonous doses of antimony have been sufficiently described. There is, however, according to authors, a form of antimonial poisoning in which neither vomiting nor purging* occurs, the symptoms being simply intense prostration, cold clammy sweat, a sense of oppression in the chest, with

* Husemann states this. Although vomiting is absent in these cases, purging is generally present. I do not remember to have seen the report of a case in which it was absent.

the respiration at first increased, then diminished in frequency and embarrassed; a rapid feeble pulse, after a time becoming slow, intermittent, and irregular; delirium, unconsciousness, tremblings, and clonic and tonic convulsions (Husemann, *Toxicologie*, p. 853).

Tardieu (*loc. cit.*, p. 608) states that in some cases of tartar emetic poisoning a rash exactly resembling that produced by the external application of the drug has appeared all over the body on the fourth or fifth day.

As already stated, in the vast majority of cases there are to be found, after death from antimonial poisoning, very decided traces of inflammation of the stomach and bowels; in some cases, however, these appear to be wanting. The venous system is generally very much engorged, and the viscera are intensely congested. Magendie asserted that in animals poisoned by tartar emetic the lungs are always full of portions apparently hepatized; but Ackermann (*loc. cit.*, p. 544), in twenty experiments, found only some marginal emphysema and sub-pleural ecchymoses, with, in one or two cases, spots of atelectasis in the lungs. The assertion of Magendie, therefore, is too sweeping; but it is true that, in a large proportion of fatal cases of antimonial poisoning, emphysema, pulmonary apoplexy, atelectasis, or other structural lesions of the lungs exist. The blood usually coagulates imperfectly.

Dr. Salkowsky (*Virchow's Archiv*, Bd. xxxiv. p. 78, 1865), of Moscow, has found that when animals are fed upon antimonious acid (one-half to one gramme daily) or other preparations of the metal for from fourteen to nineteen days, the liver, kidneys, and even the heart undergo a fatty degeneration; also that there is a lessening of the amount of glycogen in the liver, and in some cases even a total disappearance of it. This has been confirmed by Professors Grohe and Mosler, who state that in the duchy of Brunswick the peasantry give to the geese, when producing the famous fatty livers, a certain quantity of the white oxide of antimony every day.

The minimum fatal dose of tartar emetic is not known. Three-quarters of a grain in a child, and two grains in an adult, have proved fatal; but in the latter case extrinsic circumstances favored the result (Taylor, *Guy's Hospital Reports*, Oct. 1857, an analysis of thirty-seven fatal cases); two hundred grains have been recovered from (case, *Taylor's Medical Jurisprudence*, 1873, p. 309); also one hundred and seventy grains (*N. Y. Med. Rec.*, xxiv. 401).

Chronic Poisoning.—According to Mayerhofer (*Heller's Archiv*, 1846, quoted by Taylor), the symptoms following the criminal administration of small doses of tartar emetic at intervals are nausea, mucous and bilious vomiting, watery purging, often followed by constipation, small frequent pulse, and asthenia, deepening into death from exhaustion.

The treatment of antimonial poisoning consists in washing out the alimentary canal with large draughts of *tannic acid*,—the best known antidote,—and in the use of opium and of internal and external stimulants.

ADMINISTRATION.—The sudorific dose of tartar emetic is one-twelfth of a grain, the emetic dose one-half to one grain, repeated every twenty minutes as necessary. The *Antimonial Wine* (*Vinum Antimonii*, 0.4 of 1 per cent., U.S.) contains about two grains of tartar emetic in the ounce. The full emetic dose is half a fluidounce. The *Unguentum Antimonii* (tartar emetic, one part in five) is employed externally as a counter-irritant. A small quantity is spread upon a linen rag and laid upon the skin, or a little of it may be well rubbed in twice a day. Whenever it is persistently used, there comes on, sooner or later, a peculiar burning or tingling pain, which is very shortly followed by pustulation. The effect of the drug is very persistent as well as severe, so that the remedy is applicable only to a few cases in which an action of the kind spoken of is required. Care must be exercised not to continue the application too long, lest severe and obstinate ulceration be produced.

VERATRUM VIRIDE. U.S.

The rhizome and roots of *Veratrum viride*, a coarse perennial herbal plant, indigenous to the Northern United States. It is a large tapering rhizome, an inch or two in length, less than an inch in thickness at the base, and having a bitter acrid taste. It contains two alkaloids, *jervine* and *veratroidine*, which are so closely associated with the resin as to be separated from it with great difficulty. The nature of these alkaloids has been the subject of much discussion among chemists. Mr. Charles Bullock was, I believe, the first to separate them one from the other, and to prove the inertness of the resin. In accordance with the belief of Mr. Bullock that these alkaloids were distinct from all previously discovered, Dr. George B. Wood named them *viridine* and *veratroidine*. Dr. Peugnet subsequently showed that *viridine* is identical with *jervine*, previously described by Simon, from *Veratrum album*. Mr. Micheli (*Proc. Amer. Pharm. Assoc.*, 1874) confirmed this, and concluded, with Peugnet and Bullock, that *veratroidine* is distinct from *veratrine*. In 1876 (*Amer. Journ. Pharm.*, 1876, p. 1) Professor Wormley arrived at the conclusion that *veratroidine* is identical with *veratrine*. Without intending to deny the conclusions of Professor Wormley, I shall, in the present edition, allow the text of the old edition to stand, so far as concerns the names employed to represent the two alkaloids of *veratrum viride*. *Jervine* is so closely united with the inert resin that it is separated from it with great difficulty.

PHYSIOLOGICAL ACTION.—In treating of the physiological action of *veratrum viride*, I shall first speak of the effects of its alkaloids singly. When an animal is poisoned with *jervine*, the first symptom manifested is sluggishness, as shown by a disposition to be quiet, accompanied by distinct signs of muscular weakness. In a little while peculiar rapidly-repeated thrills run through the muscular system, so that the animal trembles violently. After a greater or less length of time the animal becomes unable to stand, from weakness, and at or before this period

violent convulsions appear,—general clonic spasms without rigidity. The convulsions alternate with intervals of relaxation, and as the animal grows more profoundly prostrated are less severe, but they continue in most cases up to death. Even when they are most violent, force is evidently wanting. The animal is totally unable to raise himself from the ground; the pigeon drives himself forward upon his breast, the rabbit pushes himself along on his belly, or lies upon his side and kicks into the air. Sensation appears to be benumbed only very late in the poisoning, and consciousness is preserved almost to the last. The pupils are not affected. There is no purging or vomiting, but always profuse salivation. Respiration ceases before cardiac action, so that death probably takes place from asphyxia.

The circulation is profoundly affected. The pulse is generally, if not always, lessened in frequency, *provided the animal be quiet*. When there are convulsions, or even when the tremors are marked, it becomes very rapid. The arterial pressure is greatly lowered, falling progressively from the beginning to the end of the poisoning. The force of the individual beat appears not to be much altered at first.

In an elaborate series of experiments (*Phil. Med. Times*, vol. iv.) I found that jervine had *little or no effect on the pneumogastric nerves*, since it acts as usual after those nerves have been cut, and galvanization of the par vagum in animals profoundly affected by the poison produced the usual cardiac results. Further, when the cord was cut very high up, so as to paralyze the accelerators, jervine still lessened the pulse-rate. As it was also proved that the alkaloid lessens the arterial pressure after division of the cord, *i.e.*, after vaso-motor paralysis, and also that it paralyzes the heart of the frog or turtle when placed directly upon it, it follows that jervine *lowers the force and frequency of the cardiac beats independently of its nerves, by a direct action on the cardiac muscle or its contained ganglia*. When the nerve-trunks were galvanized in an animal poisoned with jervine, although the pain-cries showed that the afferent nerves were not paralyzed, little or no rise occurred in the arterial pressure. It seems, therefore, that the jervine not only acts on the heart, but is also a *powerful depressant to the vaso-motor nerve-centres*.

In frogs, as well as in higher animals, poisoned with jervine, there is a very marked diminution and finally abolition of reflex activity; and, as the functions of neither peripheral nerves nor muscles are interfered with, it is evident that the alkaloid is an intensely powerful spinal depressant. The convulsions are cerebral in their origin, as they do not occur below the point of section when the spinal cord is divided.* Locally, jervine is very feebly if at all irritant.

The general symptoms induced by *veratroidine* resemble those caused

* Some of the conclusions of my first investigation (*American Journ. Med. Sci.*, 1870) of this drug were called in question, but I have in my last paper gone over the whole ground afresh. The earlier discussion may be found in the *Phil. Med. Times*, vols. ii. and iii.

by its congeneric alkaloid, but it is decidedly more irritating than the latter, and always induces vomiting, and occasionally purging. In poisoning by it there are in most cases some muscular twitchings, and finally marked convulsions, but neither of these are so severe and so repeated as in the case of jervine. Death takes place from asphyxia, due to paralysis of the respiratory centres.

Upon the spinal cord, the peripheral nerves, and the muscles, veratroidine acts very much as does jervine, being a decided spinal depressant.

The action of veratroidine upon the circulation is a very curious one. After a hypodermic injection of the poison the rapidity of the pulse and the arterial pressure are at first decidedly lessened. After a time, the pulse still remaining very slow, the individual heart-beats become endowed with a force greatly beyond normal, and the arterial pressure becomes normal; then suddenly the pulse-rate becomes very rapid, the individual cardiac beats losing much of their extraordinary vigor, but the arterial pressure rising nearly fifty per cent. beyond its original position.

When the alkaloid is thrown directly into a vein, these phenomena are intensified and abbreviated. I have seen the arterial pressure fall to zero in thirty seconds, and in one and a quarter minutes rise to 165 (110 normal) centimetres. The rise is not due to a direct action of the drug, but to the sudden asphyxia which it induces, since it does not occur if free artificial respiration be maintained (*Phila. Med. Times*, vol. iv.).

When artificial respiration is kept up, veratroidine steadily lessens both arterial pressure and pulse-rate. When the par vagum has been divided, artificial respiration being maintained, veratroidine is powerless to reduce the pulse-rate; and when the pulse-rate has been reduced by the drug in the uninjured animal, division of the par vagum is followed by an enormous rise in the number of cardiac beats per minute. These facts certainly prove that veratroidine is a powerful stimulant to the inhibitory nerves of the heart. Moreover, I have found that when the spinal cord is divided so as to paralyze the accelerator nerves, a minute dose of the poison (one-thirtieth of a grain) will at once cause diastolic arrest of the heart's action, but if the pneumogastria be now severed, and the repressive force be thus taken off, the relaxed, seemingly dead viscus recommences its beat. The slow pulse of mild veratroidine-poisoning becomes rapid when a large dose of the poison is injected. Further, after a large dose division of the pneumogastria has no effect upon pulse-rate, and the most intense galvanic current applied to the peripheral ends of the divided nerves is powerless to affect the viscus. Evidently, large doses of veratroidine paralyze the cardiac inhibitory apparatus, while small ones stimulate it intensely. The paralysis is certainly peripheral; whether the stimulation is centric or peripheral has not as yet been determined. When enormous

doses of veratroidine are thrown directly on the heart by venous injection, they at once kill the cardiac muscle. Upon the vaso-motor nerves veratroidine in moderate toxic amounts has no demonstrable influence. Dr. F. Reigel (*Pfuger's Archiv*, 1871, p. 409) has demonstrated that the rise of arterial pressure which occurs in asphyxia is largely due to vaso-motor spasm. In jervine-poisoning asphyxia has very little influence upon the arterial pressure, because the vaso-motor centres are paralyzed; in veratroidine-poisoning the slightest intermission in the working of the bellows of the apparatus for artificial respiration is followed at once by an enormous rise of the mercury in the manometer,—conclusive proof that the vaso-motor centres are not seriously affected. This deduction I have experimentally corroborated by galvanization of a sensitive nerve: always, unless an enormous amount of the alkaloid had been given, the rise in the arterial pressure was marked and immediate. In estimating the physiological action of veratroidine it must be borne in mind that artificial respiration was maintained during the study of the action of the drug on the heart and vaso-motor centres; that its influence on the respiratory centres is so intense as to overbalance its cardiac action, and, when the animal is left to itself, to cause death before any very decided influence has been exerted on the heart. The action of the alkaloid may, therefore, be summed up as follows: it is a *powerful respiratory poison, lessening at first the frequency of the cardiac beat by stimulating the pneumogastriacs, but soon losing all control over the heart, owing to the powerful influences which the induced asphyxia exerts.*

The resin of *veratrum viride*, when completely deprived of the alkaloids, is nearly inert. It seems, however, to be irritating to the digestive organs, and very probably aids in the production of the vomiting occasioned by full doses of the drug.

As the action of the alkaloids of *veratrum viride* is very similar, and as they are the only active principles of the drug, it is very easy *a priori* to determine what the influence of the drug will be. Sufficiently numerous experiments* have been performed with the crude drug, or its preparations, to show that it acts upon the lower animals as upon man; but it is not necessary here to do more than allude to them. When taken in small doses by man, *veratrum viride* first reduces the force without much lessening the frequency of the pulse, but after a time the pulse falls very much in rapidity, sometimes, according to Dr. Norwood, even to thirty-five a minute.

If any exertion be made during this stage of depression, the slow pulse will be suddenly converted into an exceedingly rapid one. The slow pulse is sometimes moderately full, but is always very soft and compressible; the rapid pulse is exceedingly feeble and small, often

* See especially paper by Professor S. B. Percy, *Trans. Amer. Med. Assoc.*: reprinted as pamphlet, 1864.

thready, and may become imperceptible. Severe nausea and vomiting accompany or follow the reduction of the pulse-rate. That the latter is not due to gastric disturbance is, however, shown by the fact that it often precedes the stomachic symptoms, and may exist without them. Thus, Professor Percy states that he has seen the pulse reduced to thirty per minute without nausea being induced. During the stage of depression there is always decided muscular weakness and relaxation.

After a poisonous dose the symptoms above noted are increased in intensity and become very alarming. A running, almost imperceptible pulse; a cold, clammy skin; intense nausea, and incessant attempts at vomiting, or retching, or hiccough; absolute muscular prostration; faintness; vertigo; loss of vision, and semi-unconsciousness, make up the group of extreme symptoms. Various observers also speak of an excruciating præcordial pain; but this I have not seen.

Summary.—From these symptoms, with what has already been said about the alkaloids, it follows that *veratrum viride* is a powerful spinal and arterial depressant, exerting little or no direct influence upon the cerebral centres. In full therapeutic doses it lowers the pulse-rate both by a direct action on the muscle (jervine) and by stimulating the inhibitory nerves (veratroidine); it diminishes the force of the heart-beat by a direct influence on the cardiac muscle (jervine), and produces a general vaso-motor paralysis (jervine) more or less complete according to the size of the dose.* Under its action the functional activity of the skin is greatly increased; but, as this is a necessary result of the profound arterial depression, there is no reason for believing that the drug has any specific influence upon the perspiratory glands. In a similar manner the excretion of bile is often indirectly increased by *veratrum viride*, through the severe vomiting which it induces.

American hellebore undoubtedly lowers animal temperature very decidedly, but whether directly or indirectly has not been determined. I have frequently seen it reduce the bodily heat, and M. Linou (*Bull. Thérap.*, 1869, lxxvi. 95) states that it does so, but not so certainly as it lowers the pulse. Oulmont (*Bull. Thérap.*, 1868, lxxiv. 153) asserts, as the results of his experiments, that in animals from half an hour to two hours after the administration of such doses as would produce violent symptoms without killing, the temperature fell 2°, 3°, or even 5° (C.?), and remained at this point for twenty-four hours.

THERAPEUTICS.—With our present knowledge of the physiological action of *veratrum viride*, it is evident that there are only two rational indications for its use,—namely, to *reduce spinal action* and to *reduce arterial action*. Owing to the very great effect *veratrum viride* has upon the circulation, and to the numerous drugs which are purer spinal

* Professor S. R. Percy states that a dilatation of the blood-vessels of the frog's web and bat's wing can be readily seen by the microscope to follow the administration of the drug.

depressants, it is never called for to meet the first indication, and in practice should simply be used to lessen the force of the circulation. The use of the drug in *typhoid fever* and other adynamic diseases is simply an irrational and dangerous practice, founded upon an erroneous idea of the action of the remedy.

Veratrum viride has been recommended in *mania a potu*; and in cases of irritation of the brain from drink, with strong bounding pulse, it may be of great service; but in the true *delirium tremens*, with universal adynamia, it is a thoroughly improper remedy, capable of deepening the prostration into fatal exhaustion: indeed, I have known of death occurring in this disease from its use.

When true sthenic arterial excitement is to be combated in any disease, except it be *gastritis*, *veratrum viride* may be employed as a prompt, thoroughly efficient, and at the same time very safe remedy,—very safe, since it is almost incapable of producing death in the robust adult, unless used with great recklessness and in repeated doses. In the early stages of *sthenic pneumonia* it offers, I believe, the best known method of reducing the pulse-rate and the temperature, and of ameliorating the disease.* It is hardly necessary to mention other individual diseases in which *veratrum viride* may be employed to carry out the present indication.

In *peritonitis* its tendency to cause vomiting is very much against its use, and, unless this action can be controlled, should interdict its employment. I desire, however, to call attention to its value in preventing inflammation after severe *abdominal injuries*,—indeed, after any severe injury. Thus, I am cognizant of the case of a woman whose belly was torn open by the horn of a bull; the abdominal walls were rent for about six inches, and the sigmoid flexure of the colon came out and was dragged in the dirt. It was washed, replaced, the wound sewed up, the patient restricted to low diet, and *veratrum viride* administered very carefully so as to keep the pulse as depressed as possible and at the same time to avoid vomiting, to aid in which opium was also given. Recovery without a bad symptom resulted.†

As an emetic, *veratrum viride* should never be employed.

In chronic cardiac diseases it may be used in precisely those cases in which digitalis is contra-indicated,—i.e., where there is excessive hypertrophy.

The contra-indications to the use of *veratrum viride* are cardiac weakness and the existence of general adynamia.

Toxicology.—Although *veratrum viride* is a remedy of great power, capable of producing the most alarming symptoms, yet I believe it to be the safest of all the cardiac depressants; certainly it is far less dan-

* Compare Oulmont, *Bulletin de Thérapeutique*, t. lxxiv. p. 146, and MM. Zuber and B. Pirta, *Ibid.*, t. lxxvi. p. 468.

† Consult also Dr. C. S. Bishop, *American Journal of the Medical Sciences*, Oct. 1861.

gerous than aconite. Overdoses of it provoke vomiting so soon and so certainly that it is somewhat doubtful whether a robust adult could be killed by a single dose of any of its officinal preparations, especially if prompt and judicious treatment were afforded. I have several times known a teaspoonful of its fluid extract to be taken; and Professor Percy cites recoveries after the ingestion of a tumblerful of the tincture; after thirty grains of the resinoid; after two doses—a tumblerful each—of a syrup representing a pound of the root to the pint. A feeble child, eighteen months old, was killed by thirty-five drops of the tincture (*Amer. Journ. Pharm.*, 1865), and a doubtful case of fatal poisoning in the adult is mentioned in *Med. and Surg. Rep.*, xl. 372.

I have seen the most alarming symptoms result from large medicinal doses repeated at short intervals, and have been astonished at the rapidity with which they yielded to treatment; but Dr. J. D. Blake reports (*American Med. Weekly*, No. 20, 1874) a death resulting from the administration of between three and four drops of Norwood's tincture every two hours to a babe eleven months old; and a man, convalescing from typhoid fever, was killed by a drachm of the fluid extract (*Phila. Med. Times*, xiv. 863).

In cases of poisoning, vomiting should be encouraged by large draughts of warm water until the stomach is well washed out. Then the patient should be forced to lie flat upon the back, with the head lower than the feet, and the efforts at vomiting should be restrained. If they cannot be checked, and if the prostration be severe, on no account should the patient be allowed to rise up, but must be made to vomit into a towel. A full dose of laudanum should be given by the rectum, and brandy or whisky be administered by the mouth. I have noticed that spirits will sometimes be retained only when given undiluted, and in such form will quiet the stomach at once. If the stomach refuses alcohol in any shape, the rectum should be made use of. Ammonia may be employed as an adjuvant to alcohol, and in extreme cases may be injected into a vein. Nitrite of amyl inhalations are said to have been of service. External heat is important, and mild flagellations, rubbing with coarse towels, sinapisms, etc., may be used to keep up the external capillary circulation.

ADMINISTRATION.—In administering *veratrum viride*, it should always be borne in mind that it will do no good in acute disease unless given in increasing doses until its physiological action is manifested. In almost all cases vomiting is to be avoided as far as possible. To do this, small quantities of the drug should be given at short intervals, and corresponding doses of laudanum (five to ten drops) should be exhibited fifteen minutes before each dose of the *veratrum viride*. An hour is generally the best interval between the doses. The drug should always be administered in the form of the *fluid extract* (*Extractum Veratri Viridis Fluidum*, U.S.), dose, one to three drops; or of the *tincture* (*Tinctura Veratri Viridis*,—40 per cent., U.S.), dose, three to six drops.

A saturated tincture is sometimes kept in the shops under the name of *Norwood's tincture*.

VERATRUM ALBUM.—In cases of human poisoning with veratrum album the symptoms* have been—excessive vomiting, generally accompanied by severe abdominal, and often œsophageal, pain, and followed by a very severe diarrhœa; intense prostration and muscular relaxation; very pronounced reduction of the temperature and pulse, the latter being sometimes rapid and almost imperceptible in the advanced stages, and finally becoming extinct; sunken eyes, contracted, anxious countenance, a cold skin clammy with profuse perspiration, and other evidences of collapse. The mind remains clear until the last. A fatal result is very common, and, when recovery occurs, the convalescence is usually protracted.

The exact nature of the active principles of veratrum album is still involved in doubt. Pelletier and Caventou thought that they found supergallate of veratrine in it. So far as I can make out from the authorities at my command, Simon† claims that there are three alkaloids in veratrum album,—*veratrine*, *barytine*, and *jervine*; and Dr. Mossel (*Sur la Vératrine*, Thèse, Paris, 1868) certainly indicates that *sabadilline* and *barytine* are the same. The subject has been elaborately investigated by Dr. Chas. L. Mitchell, who has found two alkaloids in the rhizome, one of which he denominates *jervine*, the other *veratralbine*. The resin, when entirely freed from alkaloids, is inert. In a number of experiments made separately by Mr. Mitchell, Dr. J. R. Haynes, and myself, the veratralbine proved itself a most active poison, one-tenth of a grain killing a large pigeon in four minutes, and one-twentieth of a grain a dog of fourteen pounds' weight in one hour. The symptoms were nausea and vomiting, with violent purging, if the animal lived some time, salivation, muscular weakness passing into paralysis, convulsions, and death,—from failure of respiration after moderate toxic doses, from cardiac arrest after very large ones. When the fatal result had been slowly produced, intense hyperæmia of the intestinal mucous membrane was found after death. Veratralbine appears to be very closely allied both in chemical and in physiological properties to veratrine.

VERATRINA. U.S.

This alkaloid is procured from the seeds of *Veratrum Sabadilla* (*Asagrea officinalis*†). As found in commerce, it is almost always more or less impure, and occurs as a grayish-white powder of an intensely acrid taste, and producing, even in the minutest quantity, when smelled,

* For cases and analysis of symptoms, see *New York Med. Record*, p. 121, 1872.

† I have not had access to Simon's original papers.

‡ The action of *sabadilline*, the congeneric alkaloid of veratrine, has been partially studied by Dr. I. Urpav (*Montpellier Méd.*, 1883, l. 274), who finds it to have only about one-twelfth the toxic power of veratrine.

frequently-repeated sneezing, which may continue for hours. It has when pure been considered uncrystallizable, but Merck has obtained it in rhombic prisms about half an inch in length, through the spontaneous evaporation of its alcoholic solution. It is very slightly soluble in boiling water, not at all in cold water; soluble in alcohol, in six parts of ether, and in two parts of chloroform.

Veratrine dissolves in concentrated sulphuric acid, with the production of a yellow color, changing in five minutes into orange, then into blood-red, and in half an hour into a splendid carmine. Masing states that this test is very faint with 0.0026 of a grain. If some bromine be dropped into the freshly-prepared sulphuric acid solution, a beautiful purple results. A more delicate test than either of those yet noted is, according to Masing, that of Trapp, which consists in warming the colorless solution of veratrine in concentrated hydrochloric acid, when a dark-red very persistent color is produced. This test is said to afford very marked proof of the presence of 0.0026 of a grain of the alkaloid, and to be especially useful when the veratrine is impure.

PHYSIOLOGICAL ACTION.—Veratrine is exceedingly irritating to any surface it may come in contact with, producing when given hypodermically or endermically severe pain, and when rubbed on the skin a feeling of warmth, followed by prickling, severe pain, numbness, and, if its use be persisted in, a marked redness. On the mucous membranes its action is even more decided. In the nostrils the minutest portion of it produces intense irritation, as shown by repeated sneezing and free discharge, which may be bloody. Upon the tongue a speck causes burning, with free salivation.

When taken internally, in small doses, it produces slowing and weakening of the pulse; more freely administered, indications of gastrointestinal irritation; and in large doses it is followed by violent vomiting, serous purging, often with intense burning in the mouth and throat, and general muscular weakness. No fatal case of poisoning is on record;* but in the experiments of Esche on himself a half-grain of the acetate produced collapse, with a pale, cold, wet skin, pinched features, a rapid, thready, irregular pulse, violent vomiting, and marked muscular tremblings. Other observers have noted more pronounced indications of convulsions; and, according to Bardsley, when absorbed through the skin, instead of purging it produces in some cases very free diuresis. On the whole, the resemblance between the symptoms as induced in man and in the lower animals is, so far as we know, complete.

The phenomena of veratrine-poisoning in a mammal are violent muscular twitchings and convulsions, which are often plainly excited by external irritants, severe vomiting, generally but not always accom-

* In *St. George's Hospital Reports*, 1870, vol. v., Dr. C. Paget Blake reports a case of recovery after the ingestion of a liniment supposed to contain three grains of veratrine! Intense itching of the skin was a prominent symptom.

panied by purging, and disturbance of motion, respiration, and circulation. The pulse is at first, if the dose be not too large, quickened and strengthened, but in a very short time it becomes slower and weaker, and finally very frequent, thready, and irregular. There is early a marked loss of muscular power, even in the midst of the convulsions, and the latter may give way to the quiet of paralysis, or may continue up to death.

According to the researches of Claus (*Journal of Anatomy*, viii.), veratrine in toxic doses causes first a slight fall of temperature, then a rise to about normal, and finally a fall immediately before death. Sabadilline, on the contrary, produces a rise of temperature, followed only by a partial fall, so that the bodily heat even at the moment of death is above normal.

M. Prevost (Robin's *Journal de l'Anatomie*, 1868, t. v. p. 206) has, I think, very well divided the action of veratrine in poisonous doses into three stages: first, that of excitation or restlessness; second, that of convulsions; third, that of paralysis. It should, however, be understood that these may after large doses be fused into one. I have seen an animal suffer a convulsion, or perhaps merely give a convulsive shudder, and drop dead.

After death from a very large dose, the muscles are found to have lost more or less completely their irritability, so that they either do not respond, or respond very feebly, to the strongest faradic currents. That this is due to a direct influence of the alkaloid upon them is proved by the fact, first noted by Kölliker (*Virchow's Archiv*, Bd. x. p. 257), but which I in common with other observers have experimentally confirmed, that if an artery be tied before poisoning, all the muscles supplied by that artery maintain their integrity.

It is evident that veratrine is a muscle-poison; but it has other powers, and the subject is best studied in detail, system by system.

Central Nervous System.—Upon the cerebrum the action of veratrine is not very marked. That the convulsions are not cerebral is shown by the fact, which I have frequently noted, that they are in no wise affected by division of the spinal cord. The spasms must be, therefore, either peripheral or spinal in origin. M. Prevost (Robin's *Journal de l'Anatomie*, 1868, p. 209) has found that convulsions will occur in the frog even when the spinal cord is destroyed, but that under these circumstances the convulsions are not spontaneous, but occur only when an irritation is applied to a part, and are limited to the part irritated. A fact analogous to this was noticed by Kölliker (*Virchow's Archiv*, Bd. x. p. 262, Exp. IX.): in frogs whose nerves were paralyzed by curare, the exhibition of veratrine induced phenomena similar to those just noted. These facts, however, do not prove that the convulsions in the veratrized frog are not spinal, but only show that there is a state of excitation of the muscles. But M. Prevost furnishes the following direct proof that the cord in veratrine-poisoning is not affected. The

hind legs of a frog were separated from the rest of the body by a very tight ligature, so placed as not to include the lumbar nerves. Some veratrine was then introduced into one of the fore legs, and of course found its way into the spinal cord and the anterior portions of the body. Under these circumstances it is evident that the convulsions produced, if spinal, would affect the whole body, but if peripheral would be confined to the anterior part of the frog. It was found that the posterior legs were never affected; that while irritation of them caused most violent spasms in the anterior part of the body, only the normal reflex actions occurred in those muscles which were not reached by the poison. If this experiment be confirmed (and I see no intrinsic reason to doubt its accuracy), to Prevost belongs the credit of having proved that veratrine has no action on the motor centres of the spinal cord.

There is, however, an apparent opposition between the experiments of Prevost and those of Kolliker (*Virchow's Archiv*, Bd. x. p. 261). The latter observer noted (Exp. VI.) that when the skull of the frog was opened and a ten-per-cent. alcoholic solution of veratrine dropped on the cord, violent general tetanic convulsions were induced; also (Exp. IV.) that when one crural artery and vein of a frog were tied and the veratrine solution placed in the mouth, tetanus ensued, involving the protected limb, and continuing there after it had ceased in the other members. I see no way of reconciling these experiments of Kolliker with those of Prevost except by supposing either that the latter are incorrectly observed, or, what seems much more probable, that the poison in the former reached the protected parts by diffusion although in less quantity than it did the other members: this would also explain the continuance of tetanus in the protected limb after it had ceased elsewhere.

M. Guttman (*Reichert's Archiv*, 1866) is in accord with Kolliker in his experiments, for he states that, notwithstanding the artery of limb is tied, yet spasms occur in the leg during the convulsive stage of veratrine-poisoning: of course the "diffusion" theory would apply to this as well as to the experiments of Kolliker.

The only conclusion to be drawn from the evidence seems to me to be that at present it is uncertain whether veratrine does or does not act upon the motor centres of the cord.

In regard to the action of the drug upon the sensitive centres of the cord, our knowledge is by no means perfect. Anæsthesia of the posterior feet was noticed in the frogs experimented upon by Prevost in the manner described; but when the circulation is cut off from the feet of a frog, loss of sensibility always ensues.

Peripheral Nervous System.—The study of the action of veratrine upon the peripheral motor apparatus evidently divides itself into a study of the influence upon the muscles and the extreme nerve-endings in them, and upon the nerve-trunks.

There can be no doubt that *veratrine finally destroys the contractile power of the muscle itself*, so that it fails to respond to any irritation whatever, and soon, becoming stiff, exhibits the acid reaction of post-mortem rigidity. Thus far all recent observers are in accord; and I have frequently witnessed the same phenomenon. Kolliker in some of his experiments (*loc. cit.*) notes that the muscle in the early stage of veratrine-poisoning responded inordinately to stimuli. The study of this phenomenon has been especially made by Bezold and Hirt (*Untersuch. Physiolog. Laborat. Würzburg, i.*), by M. Provost,* by Rossbach (*Pflüger's Archiv, xiii. 617*), by Murey and Maurice Mendelssohn (*Travaux du Laborat. de M. Murey, xiv.*, and *Comptes-Rendus Soc. Biolog., 1883, 147*). When a muscle during the convulsive stage of veratrine-poisoning is momentarily stimulated, instead of the usual momentary contraction a prolonged tetanic spasm results and lasts some seconds: this spasm is induced by the slightest irritation. When a nerve is irritated repeatedly within a short time, the tributary muscle loses its power of entering upon a "veratrine contraction," but if left quiet for a time recovers itself. There is therefore in veratrine-poisoning, preceding the stage of muscular paralysis, a stage of muscular hyper-excitability. To this are due no doubt in great part, if not altogether, the convulsions. It can scarcely be doubted that it is the result of an action not upon the nerve-endings, but upon the sarcolemma of the muscle.† That the muscular paralysis is of similar nature would seem to be proved by the rapid changes which take place in the muscle after death, and by the fact, noted by Guttmann (*Reichert's Archiv für Anatomie, 1866, p. 498*), that while frogs apparently dead from nerve-poisons such as atropine, strychnine, and curare often recover themselves after a period of stupor, those poisoned with veratrine never do.

When a muscle is dead, galvanization of the nerve of course elicits no response; but it is possible that a substance may be at the same time a nerve-poison and a muscle-poison. Veratrine is both a muscle-poison and a nerve-poison. Kolliker denies this, but the experimental evidence brought forward by him amounts to almost nothing. Guttmann (*loc. cit.*) asserts that in his experiments, whenever irritation of a nerve failed to elicit a response, direct irritation of the muscle was always equally unavailing. Bezold and Hirt (*loc. cit.*) experimented, with a full knowledge of Guttmann's work, with small and with large doses, and evidently with great care. They found (*loc. cit., p. 90*) that when a *small dose* is used there is at first a *very marked increase* in the irri-

* Quoted by Husemann.

† Fick and Boehm, in the elaborate paper already referred to, believe that they prove that the prolongation of the muscular contractions in veratrine-poisoning is due to a greater intensity of the chemical processes of the muscles, and not to a delay of the process of restitution. A discussion of this point would involve that of muscular physiology, and cannot be entered into here. The weak point of the argument made by Fick and Boehm may, however, be pointed out. Granting all their asserted facts, it is perfectly possible that greater intensity of the chemical processes is an *effect*, not a *cause*, of the prolonged contractions.

tability both of the nerve and of the muscle, so that, whether the current be applied directly to the muscle or indirectly through the nerve, contractions take place more readily than normal. After a time, both muscle and nerve lose their irritability, so that no contraction follows either the direct or the indirect stimulation. The process does not go on *pari passu* in the two organs. The irritability increases sooner and is sooner lost in the nerve than in the muscle, so that there is a time when galvanic irritation of the nerve fails to induce contraction, although the muscle still retains its functional power and reacts instantly to direct stimulation. Moreover, the upper or spinal end of the nerve dies first, so that at a certain stage irritation of the nerve-trunk close to its origin fails to induce contraction of the tributary muscle, although when applied lower down it elicits a response. This important observation is confirmed by Fick and Boehm (*Arbeiten Physiolog. Laborat. der Wurzbürger Hochschule*, 1873, p. 147), and by I. Ott (*Toxicological Studies*, Philada., 1874), and would seem to prove that *veratrine acts directly on the nerve-trunks*. Fick, however, affirms that under these circumstances he has frequently proved the existence of the normal muscular galvanic currents in the seemingly dead nerve-trunks, and that therefore it is only the peripheral *nerve-endings* which are attacked by veratrine. But it is difficult to reconcile this observation of Fick with some of those of Bezold and Hirt. At present, therefore, it must be considered undetermined whether it is the nerve-endings solely, or the whole peripheral nerves, which are affected by veratrine.

As already stated, the action of veratrine upon the sensory centres is doubtful; its influence upon the peripheral sensitive nerves has not, that I am aware of, been carefully worked out, but the effects of its local application to the human skin seemingly show that it first strongly excites and then paralyzes them.

Circulation.—After death from a large dose of veratrine, the heart is soft, dilated, full of blood, and incapable of responding to galvanism; *i.e.*, the heart-muscle is dead. According to Bezold and Hirt (*loc. cit.*), after a small dose there are quickening of the pulse and rise of the blood-pressure, which soon return to the normal condition; while immediate and persistent fall in the number of the heart-beats and in the arterial pressure follows a large dose. If the vagi be divided previous to the poisoning, a large dose produces a temporary increase in the pulse; and a stimulation of the distal end of the cut nerves by a current too slight to be felt in the unpoisoned animal retards very markedly the beat. From these facts it follows that in the uninjured animal, after poisoning by veratrine, there is an inhibitory retardation of the pulse, and also an excitation of the peripheral ends of the vagi. That it is not merely the peripheral inhibitory apparatus which is affected was proved by injecting the alkaloid into the carotid,—*i.e.*, into the inhibitory centre,—when there happened an instantaneous and remarkable retardation of the heart-beat, which could only have been caused

by excitation of the inhibitory centre. In a later stage of the poisoning the strongest faradic currents applied to the pneumogastrics fail to affect the heart. It is, therefore, evident that veratrine *first exalts and then destroys the functional activity of the par vagum*, in a manner parallel to its action on the spinal nerves.

When the heart is separated from the nerve-centres by section of the par vagum and of the spinal cord, veratrine produces, according to Bezold and Hirt, at first increase in the pulse and blood-pressure, secondly, lowering of both to the minimum; showing that it exerts upon the internal heart-ganglia, or upon the heart-muscle, its peculiar action of first stimulating and afterwards paralyzing functional activity. This is in accord with the results obtained by S. Ringer, who finds that veratrine acts *directly upon the cardiac muscle* as it does upon the skeletal muscles. Each excitation causes in the veratrized frog's heart a prolonged series of incoördinated contractions; therefore a lessened regulation with an increased amount of force-generation (*Arch. Med.*, 1882, p. 21).

That the poison has a similar action upon the vaso-motor centres seems probable from the facts noted by Bezold and Hirt: first, that injection into the carotid after section of the pneumogastrics causes immediate rise of the blood-pressure; second, if the mesenteric arteries have been previously bared, they can be seen to contract. This excitation is followed after a time by vaso-motor paralysis and dilatation of the vessels.*

Respiration.—Bezold and Hirt conclude, from the fact that after section of the pneumogastrics even the smallest doses of veratrine cause retardation of the respiration without previous increase, that the alkaloid *depresses and finally paralyzes the respiratory centre*.

Summary.—Locally, veratrine is a very violent irritant, and probably acts as a paralyzing poison upon all the higher tissues. Taken internally, it is a powerful muscle-poison, producing a primary stage of muscular hyper-excitability and a condition in which momentary stimuli produce tetanic spasms, and a final stage of rigidity and complete loss of contractility. It is paralyzant to the motor nerves, and probably also to the sensory nerves. Upon the cerebral centres it has little action; its exact influence upon the spinal cord has not been determined. It is a powerful depressant to the respiratory centres, and acts upon the heart muscle as upon the voluntary muscles. In the earlier stages of its action it slows the pulse and increases the blood-pressure by stimulating the inhibitory cardiac nerves, and probably also by stimulating the muscle-fibres in the heart itself and in the walls of the arterioles.

THERAPEUTIC ACTION.—The study of the physiological action of

* M. Araki states (*Compt.-Rend. Soc. Biolog.*, iv., 1892) that in the intoxication of frogs with veratrine glycosuria occurs; and M. R. Lépine believes he has found that there is in the dog poisoned with veratrine an increase in the blood of the sugar-making ferment, which ferment is later eliminated with the urine.

veratrine shows that its rational therapeutic use must be limited. As a heart-depressant, it is much inferior to aconite and *veratrum viride*, for obvious reasons, and, although it has been used as such, it has not achieved much reputation. When exhibited in full doses it is very apt to give rise to exceedingly disagreeable secondary symptoms, and has no advantage over the medicines just named. Some years ago it was employed in *acute rheumatism*, having been recommended by Turnbull, Bardsley, Piedagnel, Trousseau, and others; but it is not so efficacious in this disease as other far less dangerous remedies by which it has been superseded. The same is true of its employment in *dropsy*; and I know of no condition which would justify its internal use.

Bardsley originally used it in *neuralgia*, especially when arising from cold. He used it both internally and externally. At present it is rarely employed except as a local application. My own success with it has not been very encouraging, but others of larger experience recommend that it be rubbed over the affected nerves in *rheumatic neuralgia*.

As an external stimulant and rubefacient it is sometimes used with good effect in narcotic poisoning; also in various spinal troubles as an irritant applied to the spine, and to the skin of the paralyzed limbs, to aid in maintaining circulation; but all these indications can, I think, be better met by other means. In regard to the dose of veratrine for internal use, it should be borne in mind that one-sixteenth of a grain has produced the most alarming symptoms (Taylor, *Medical Jurisprudence*, 2d edition, London, 1873).

An ointment (*Unguentum Veratrinæ*—1 to 25) and an oleate (*Oleatum Veratrinæ*—1 to 50) are official.

ARNICÆ FLORES—ARNICA FLOWERS. U.S.

ARNICÆ RADIX—ARNICA ROOT. U.S.*

The flower-heads, rhizome, and roots of the *Arnica montana*, a perennial composite, native of Northern Europe and Asia, and said also to be found in the Northwestern United States. The yellow flowers have about fourteen striated ligulate tridendate florets in the ray, twice as long as the disk, which consists of numerous tubular florets. Of its two alkaloids, *arnicine* and *cytisine*,† the latter is said to be identical with the active principle of the laburnum (*Cytisus laburnum*).

PHYSIOLOGICAL ACTION.—Locally, arnica is stimulating, and, if in sufficient strength, decidedly irritating. Upon some skins the tincture acts even violently, rapidly developing an acute eczematous inflammation of the upper dermal layers, as manifested by hyperæmia, papules,

* This drug probably does not belong in the present class.

† Professor J. L. Provoat and Paul Binet find that *cytisine* is a powerful centric emetic, which in large doses paralyzes the motor nerves. Its direct action upon the circulation is very slight; toxic doses cause a gradual lowering of arterial pressure and death by respiratory paralysis (*Revue Méd. de la Suisse Rom.*, vii. and viii., 1887; see also H. Radziwillowicz, *Thèse* Dorpat, 1887).

vesicles, excoriations, crusts, and scales in regular sequence (*Boston Med and Surg. Journ.*, Jan. 1875; also *Ann. de Dermat. et de Syph.*, 1886, vii.)

That the influence which the drug exerts upon the general system when taken internally is very decided is certain, but the exact nature of this influence is at present unknown. The only positive knowledge that we have in regard to the physiological action of arnica is that derived from experiments made by Dr. H. A. Haro (*Bost. Med. and Surg. Journ.*, Jan. 12, 1888) in the laboratory of the University of Pennsylvania. He finds that the fluid extract in doses of five to ten drops produces in the dog a slowing of the cardiac beats, with increase of the fulness of the pulse-wave and a very slight increase of the arterial pressure, the slowing of the pulse being the result of a stimulation of the pneumogastric nerves, and the slight increase of the arterial pressure probably caused by increased heart-work. After large doses the pulse becomes very rapid, from pneumogastric paralysis, the arterial pressure remaining near the norm. Viborg (quoted by Stillé) affirms that in horses and cows it causes increased action of the heart, flow of urine, and warmth of skin, followed by very decided general depression. According to Stillé, the effects of moderate doses on man are similar to those noted as occurring in the lower animals,—namely, increase of the cardiac action, of the respiration, of the temperature of the skin, and of the perspiration and urine, along with very decided symptoms of gastric irritation. On the other hand, it is asserted that ten drops of the tincture every three or four hours act as a decided arterial depressant (Dr. C. C. Balding, *Lancet*, Dec. 1870). The symptoms of poisoning seem strangely to vary. Thus, in a woman, two cups of a strong infusion produced violent gastro-intestinal irritation, as shown by vomiting and choleraic diarrhoea, reduction of the pulse to 60, and finally collapse (*Bull. Thérap.*, lxxvi.). In Barbier's case (quoted by Stillé), an infusion of eighty grains of the flowers caused giddiness and intense muscular weakness, with spasmodic movements of the limbs. In another, not fatal, case (*Lancet*, Nov. 1864), according to the statement of the patient, an ounce of the tincture did not produce any symptoms for eight hours, when approaching collapse, dilated, immovable pupils, with a cold, dry skin, and a feeble fluttering pulse, rapidly supervened upon an intense epigastric pain, which was increased by pressure.

In a not fatal case reported by Dr. W. A. Thorn (*Virginia Medical Monthly*, Sept. 1883), four hours after ingestion of a fluidounce of a tincture by a young man, the pulse was 100, full and strong, the temperature normal, insensibility complete, conjunctiva anæsthetic, respirations 18 per minute, no vomiting or purging. Twelve hours later the patient became wildly delirious; the next day he suffered from burning pain in the abdomen, diarrhoea, and free diuresis.

THERAPEUTICS.—In the present state of our knowledge, the internal use of arnica is experimental. Externally it is employed as a stimu-

lant application in *bruises* and *sprains*, generally in the form of *tincture* (*Tinctura Arnice Florum*—20 per cent., U.S.; *Tinctura Arnice Radicis*—10 per cent., U.S.), which may be applied pure, but sometimes as fomentations of the flowers. Its property of occasionally producing intense dermal irritation should be borne in mind. An *extract* (*Extractum Arnice Radicis*), a *fluid extract* (*Extractum Arnice Radicis Fluidum*), and a *plaster* (*Emplastrum Arnice*—33 per cent.) are official.

ACONITUM—ACONITE. U.S.

The *Aconitum Napellus*,* or monkshood, is a tall perennial, indigenous in Europe, and cultivated in this country for the sake of its spike of blue flowers. The leaves are three or four inches in diameter, and cut almost to the base into three to seven three-lobed, wedge-shaped divisions.

The root, which is the only official portion, is from three to four inches long, very tapering, about three-quarters of an inch in diameter at the base. Its taste is bitterish, acrid, and after a little while benumbing, giving origin to intense tingling of the lips and mouth. It is to be distinguished from horseradish root, with which it has been sometimes fatally confounded, by its external brown color and its lack of odor when scraped. The whole plant is active and tastes like the root.

In 1833 Geiger and Hesse discovered in aconite an alkaloid, *Aconitine*, which is undoubtedly the active principle of the drug. In commerce there are several varieties of it, made by different large manufacturers: the *German aconitine*, which is very impure, and, according to Husemann, is less active than the extract; *impure English aconitine*; and the so-called *English aconitine*, prepared by Morson and said to be chemically pure. The latter is a grayish powder.†

* All the species of the genus *Aconitum* are more or less poisonous, although *A. Napellus* is the only one official. For a study of the comparative strength of the various aconites, see Schroff, *Journal für Pharmacodynamik*, 1857, p. 335. He arranges them as follows, commencing with the most virulent: *A. ferox*, *A. Napellus*, with its varieties, *acemon-tanum*, *tauricum*, and *variabile*, *A. Cammarum*, *A. paniculatum*, *A. Anthora*. The toxic properties of *A. Anthora* are very weak. *Lycetoxine* is the alkaloid of *A. lycetoxum*. For a physiological study of it by Dr. Ott, see *Phila. Med. Times*, vi. 25.

† In 1857, Hühsehmann announced the presence in minute quantity of a second alkaloid in the root of *Aconitum Napellus*,—*Napelline*. Schroff* (*Journal für Pharmacodynamik*, l. 3) could find no essential difference between its action and that of German aconitine. T. and H. Smith, of Edinburgh, have found a third, non-poisonous alkaloid, *Aconelline*, which they think to be probably identical with narootine; and Flückiger asserts that there are four alkaloids contained in the genus *Aconitum*,—namely, *Aconitine*, *Pseudoaconitine*,† *Napelline*, and *Lycetoxine* (*Sydenham Soc. Year-Book*, 1869 and 1870). Recently Dr. C. A. Wright has found that there are three alkaloids in *Aconitum Napellus*,—crystallizable aconitine, a nearly inert base, *piera aconitine*, and a third alkaloid, incapable of crystallising or of forming crystallisable salt, which is said to form frequently the bulk of commercial aconitine.

* From what Schroff says about the material he used in his experiments, it is evident that he had no proof that it was genuine napelline.

† Boelm and Ewens have physiologically studied the alkaloid of *Aconitum ferox*, under the name of *paraaconitine*, and found the difference between its action and that of aconitine to be one of degree, not of kind. It was the stronger of the two (*Archiv für Exper. Path. and Pharm.*, Bd. I., 1873).

Duquesnel (*Comptes-Rendus*, vol. lxxiii., 1864) first obtained the aconitine in the form of colorless, rhombic, tabular crystals, soluble in alcohol, benzin, and ether. extremely soluble in chloroform, very slightly soluble in water, insoluble in glycerin.

The salts of aconitine are soluble, and from their solution the alkaloid is precipitated by alkalies in an amorphous state. That aconitine is the only active principle of the root would seem to follow from the experiments of Hottot (*Journal de Physiologie*, 1864).

PHYSIOLOGICAL ACTION.—When applied to a raw surface, or to the skin, aconite, or its alkaloid aconitine, acts as a local irritant and narcotic, soon producing numbness, with tingling, which may persist for a long time. When given in sufficient dose internally, it is a violent poison, acting, so far as is known, similarly upon all animals.

If the dose be large, death may be almost immediate, and, if the alkaloid be given hypodermically, may occur in less than a minute. In such cases the result is apparently due to sudden paralysis of the heart-muscle.

After moderate toxic doses, the prominent symptoms are great disturbance of the respiration, muscular weakness, vascular depression, and finally death, with or without convulsions. As I have seen the rabbit after the injection of one-sixth or one-quarter grain of Morson's pure aconitine, the animal commences to jump vertically in a very peculiar manner, and often to squeal piteously. The jumping soon grows less and less powerful, and finally is replaced by severe convulsions, during which the animal often lies prostrate on its side. In the dog, however, the muscles have remained without a quiver during all stages of the poisoning; in the horse Harley has noticed convulsions (*St. Thomas's Hospital Reports*, v.). The convulsions are an inconstant symptom, dependent upon peculiarities of the individual or species, as well as upon the amount injected. Dilatation of the pupil frequently occurs, if it be not, indeed, a constant phenomenon. There is often severe vomiting.

The symptoms which are induced by small therapeutic doses of aconite in man are reduction of the force and frequency of the circulation, a sense of muscular inertia and weakness, and a slight tingling in the extremities or in the lips. If the dose administered be large, all these symptoms are intensified; the muscular weakness is extreme; the tingling is felt all over the body; the pulse is feeble, and reduced to thirty or forty per minute; the respirations are diminished; giddiness and disordered vision may be manifested, especially when the erect posture is assumed. After three or four hours these symptoms gradually subside.

When a poisonous dose has been ingested, the first thing noticed in most cases is a burning or tingling in the throat or in the extremities, soon spreading over the whole body. The pulse rapidly falls in frequency, and in a very little time becomes exceedingly weak, intermit-

tent, irregular, and finally imperceptible; the muscular strength is greatly reduced, and sometimes almost entirely gone; the respirations are shallow, feeble, irregular, and infrequent; the general sensibility is very much benumbed, so that marked anæsthesia of the surface is present; the skin is bedewed with a cold sweat; the countenance is anxious, sunken, livid, and the eyes are often protruded, or are even spoken of as glaring; the pupil is generally dilated, but when there are no convulsions may be contracted; gastric burning is sometimes complained of, and severe vomiting may be present, but the stomach is not rarely retentive. The intellect generally remains unaffected until very near the close, sometimes to the very moment of death.* In the collapse of the latter stages of aconite-poisoning the special senses may be lost, especially the sight. The voice is very generally extinguished. Convulsions occur in some cases, not in others; and certainly in some instances, if not always, the patient is unconscious during their continuance. Diplopia, or other disorder of vision, has been noted in some cases. Death may occur suddenly, especially directly after some exertion on the part of the patient, from syncope.

The symptoms which aconite produces in man and in the lower animals are so entirely identical that the conclusions arrived at in regard to the latter may be accepted without reserve as applicable to the former.

Circulation.—The action of aconite upon the circulation is very decided. According to Dr. Achscharumow (*Reichert's Archiv*, 1866, p. 255), in the frog a moderate toxic dose of aconitine produces at first a reduction in the number of the heart's pulsations, then an increase in the rapidity of its action, with very evident loss of power, and finally irregular systolic movements, with very long intervening pauses ending in diastolic arrest. Dr. Rudolf Boehm and L. Wartmann (*Arbeiten Physiolog. der Würzburger Hochschule*, 1873) have substantially confirmed these observations.

In the higher animals the exhibition of aconite in sufficient doses yields similar results. In the dog and cat (Boehm and Wartmann, and my own experiments) there is a steady sinking of the arterial pressure. In the rabbit, according to Boehm and Wartmann, the fall of pressure is preceded by a brief rise; this rise has also been noticed in the dog by Laborde and Duquesnel (*Des Aconits*, p. 130). The rate of the heart's pulsation also undergoes reduction, and there is finally diastolic arrest in dogs as in other mammals.

The method by which the aconite influences the heart is not certainly settled. According to the experiments both of Boehm and of Wartmann, it produces a gradual paralysis of the peripheral vagi, a constant increase of the intensity of a galvanic stimulation of the pneumogastric nerves being required to influence the heart as the poi-

* Pereira, however, states that in some recorded cases stupor has occurred.

soning deepens, until finally the vagi entirely refuse to transmit any inhibitory impulse.

In a single experiment, Achscharumow (*loc. cit.*, p. 272) found that after section of the vagi in the early stage of aconite-poisoning there was an immediate rise both in the number of the cardiac pulsations and in the arterial pressure. From these data he argues that the slowing of the pulse during the early stage of aconite-poisoning is due to stimulation of the inhibitory centres in the medulla oblongata. Boehm and Wartmann (*loc. cit.*) repudiate this conclusion, because, according to their experience, the phenomena of aconite-poisoning occur in the usual manner after section of the vagi, or in atropinized animals. It is evident that there is no necessary contradiction in the asserted facts of these observers, as it is possible that the slowing of the pulse may be due to two immediate causes, one having its seat in the medulla oblongata, the other in the heart. Although this explanation cannot be considered proved, it is probably correct. Professor Plugge confirms the statement of Boehm and Wartmann, that aconitine finally paralyzes the peripheral vagus, while Lewin agrees with Achscharumow that there is a primary rise of the pulse when aconitine is given after section of the vagi, but states that this rise is of very brief duration and is soon followed by the usual reduction (*Prager Vierteljahrs.*, Bd. cxxxi.). It is very certain that aconitine also influences directly the heart or its contained ganglia, for Achscharumow (*loc. cit.*, p. 262) has found that it acts upon the frog's heart removed from the body, and Liégeois and Hottot (*Journal de Physiologie*, p. 520, 1861) have observed the ordinary cardiac phenomena of aconite-poisoning produced by the alkaloid placed directly upon the viscus. Boehm and Wartmann have also noted that in aconite-poisoning the force of the individual beat is lessened. In the experiments of Laborde and Duquesnel, the cardiac beats were at first rendered very slow, but very full and forcible, and afterwards became very rapid and very feeble (*loc. cit.*). After death the cardiac muscle fails entirely to respond to galvanic irritation, its contractility being lost.*

Our knowledge of the action of aconitine upon the vaso-motor nerves is not complete. Achscharumow, Dr. F. B. Nunneley (*Proc. Royal Society*, p. 46, 1870), and still more recently Dr. Mackenzie, have studied with the microscope the influence of injections of aconitine upon the vessels of the frog's web, but have been unable to detect any alteration of their calibre. The first observer has also found that after division of the sympathetic in the neck, galvanization of the peripheral end produces the usual phenomena, even in the most advanced stages of aconite-poisoning. These facts indicate very strongly that

* Opposed to all this evidence are the extraordinary and at present inexplicable statements of Mackenzie (*Practitioner*, xxi. 109), that aconitine has no effect upon the heart, and if applied directly to it does not seriously affect its pulsations.

tent, irregular, and finally imperceptible; the muscular strength is greatly reduced, and sometimes almost entirely gone; the respirations are shallow, feeble, irregular, and infrequent; the general sensibility is very much benumbed, so that marked anesthesia of the surface is present; the skin is bedewed with a cold sweat; the countenance is anxious, sunken, livid, and the eyes are often protruded, or are even spoken of as glaring; the pupil is generally dilated, but when there are no convulsions may be contracted; gastric burning is sometimes complained of, and severe vomiting may be present, but the stomach is not rarely retentive. The intellect generally remains unaffected until very near the close, sometimes to the very moment of death.* In the collapse of the latter stages of aconite-poisoning the special senses may be lost, especially the sight. The voice is very generally extinguished. Convulsions occur in some cases, not in others; and certainly in some instances, if not always, the patient is unconscious during their continuance. Diplopia, or other disorder of vision, has been noted in some cases. Death may occur suddenly, especially directly after some exertion on the part of the patient, from syncope.

The symptoms which aconite produces in man and in the lower animals are so entirely identical that the conclusions arrived at in regard to the latter may be accepted without reserve as applicable to the former.

Circulation.—The action of aconite upon the circulation is very decided. According to Dr. Achscharumow (*Reichert's Archiv*, 1866, p. 255), in the frog a moderate toxic dose of aconitine produces at first a reduction in the number of the heart's pulsations, then an increase in the rapidity of its action, with very evident loss of power, and finally irregular systolic movements, with very long intervening pauses ending in diastolic arrest. Dr. Rudolf Boehm and L. Wartmann (*Arbeiten Physiolog. der Würzburger Hochschule*, 1873) have substantially confirmed these observations.

In the higher animals the exhibition of aconite in sufficient doses yields similar results. In the dog and cat (Boehm and Wartmann, and my own experiments) there is a steady sinking of the arterial pressure. In the rabbit, according to Boehm and Wartmann, the fall of pressure is preceded by a brief rise; this rise has also been noticed in the dog by Laborde and Duquesnel (*Des Aconits*, p. 130). The rate of the heart's pulsation also undergoes reduction, and there is finally diastolic arrest in dogs as in other mammals.

The method by which the aconite influences the heart is not certainly settled. According to the experiments both of Boehm and of Wartmann, it produces a gradual paralysis of the peripheral vagi, a constant increase of the intensity of a galvanic stimulation of the pneumogastric nerves being required to influence the heart as the poi-

* Pereira, however, states that in some recorded cases stupor has occurred.

soning deepens, until finally the vagi entirely refuse to transmit any inhibitory impulse.

In a single experiment, Achscharumow (*loc. cit.*, p. 272) found that after section of the vagi in the early stage of aconite-poisoning there was an immediate rise both in the number of the cardiac pulsations and in the arterial pressure. From these data he argues that the slowing of the pulse during the early stage of aconite-poisoning is due to stimulation of the inhibitory centres in the medulla oblongata. Boehm and Wartmann (*loc. cit.*) repudiate this conclusion, because, according to their experience, the phenomena of aconite-poisoning occur in the usual manner after section of the vagi, or in atropinized animals. It is evident that there is no necessary contradiction in the asserted facts of these observers, as it is possible that the slowing of the pulse may be due to two immediate causes, one having its seat in the medulla oblongata, the other in the heart. Although this explanation cannot be considered proved, it is probably correct. Professor Plugge confirms the statement of Boehm and Wartmann, that aconitine finally paralyzes the peripheral vagus, while Lewin agrees with Achscharumow that there is a primary rise of the pulse when aconitine is given after section of the vagi, but states that this rise is of very brief duration and is soon followed by the usual reduction (*Prager Vierteljahrs.*, Bd. cxxxi.). It is very certain that aconitine also influences directly the heart or its contained ganglia, for Achscharumow (*loc. cit.*, p. 262) has found that it acts upon the frog's heart removed from the body, and Liégeois and Hottot (*Journal de Physiologie*, p. 520, 1861) have observed the ordinary cardiac phenomena of aconite-poisoning produced by the alkaloid placed directly upon the viscus. Boehm and Wartmann have also noted that in aconite-poisoning the force of the individual beat is lessened. In the experiments of Laborde and Duquesnel, the cardiac beats were at first rendered very slow, but very full and forcible, and afterwards became very rapid and very feeble (*loc. cit.*). After death the cardiac muscle fails entirely to respond to galvanic irritation, its contractility being lost.*

Our knowledge of the action of aconitine upon the vaso-motor nerves is not complete. Achscharumow, Dr. F. B. Nunneley (*Proc. Royal Society*, p. 46, 1870), and still more recently Dr. Mackenzie, have studied with the microscope the influence of injections of aconitine upon the vessels of the frog's web, but have been unable to detect any alteration of their calibre. The first observer has also found that after division of the sympathetic in the neck, galvanization of the peripheral end produces the usual phenomena, even in the most advanced stages of aconite-poisoning. These facts indicate very strongly that

* Opposed to all this evidence are the extraordinary and at present inexplicable statements of Mackenzie (*Practitioner*, xxi. 109), that aconitine has no effect upon the heart, and if applied directly to it does not seriously affect its pulsations.

aconite does not affect the vaso-motor nerves, and this indication is confirmed by the experiments of Boehm and Wartmann, who found that when in aconite-poisoning a galvanic current was applied to the vaso-motor centres in the medulla, an immediate rise of arterial pressure took place. As stimulation of a sensitive nerve produced at such time no rise of arterial pressure, the conclusion would appear to be logical that aconitine, while not affecting the efferent vaso-motor nerves or the vaso-motor centres, destroys the conducting power either of the afferent nerves or of the cord, so that in the aconitized animal the usual impulses from the periphery are unable to reach the vaso-motor centres and provoke the reflex impulses which normally keep the vessels in contraction.

Nervous System.—Such diverse experimental results have been reached by different investigators that it is very difficult to draw any positive conclusion from the evidence. Achscharumow concludes that the paralysis and loss of reflex activity induced depend upon the destruction of the conducting power of the peripheral motor nerves, because he has found that when a frog is poisoned after the abdominal aorta has been tied, reflex and voluntary activity is preserved in the hind legs long after it has been lost in the anterior portion of the body; and, at the same time, while the brachial nerves, as tested by galvanic stimulation, have lost their power of transmitting impulses, the protected ischiatic nerves have preserved their functional ability. The very recent experiments of Professor P. O. Plugge (*Virchow's Archiv*, Bd. lxxxvii. p. 410) confirm these experiments of Achscharumow, showing, however, that it is the peripheral ends of the motor nerves which are affected, since, when in the frog's leg the lower portion had been protected from the poison, galvanization of the nerve-trunk a considerable distance above the point of protection caused response in the tributary muscles. This concurrence of testimony would seem to prove that aconitine paralyzes the peripheral motor nerves. The testimony, however, to the contrary of this is strong. Boehm and Wartmann in many experiments with Merck's aconitine found that both the nerves and the muscles in poisoned animals preserve their normal excitability until death; they also determined that tying all the structures of a limb except its nerve did not prevent the usual development of paralysis when the poison was exhibited. In the elaborate research of Liégeois and Hottot, to be spoken of in detail directly, when all voluntary reflex actions were lost, the motor nerves and muscles were still found excitable. Mackenzie and A. Guillaud (*Arch. de Physiol.*, 1875) also bear testimony to the same effect. The explanation of this conflict of testimony is not to be found, as has been suggested by C. Ewers (*Arch. f. Exper. Path. u. Pharm.*, i., 1873), in the use of different species of frogs, because Plugge employed various species; nor is it in the employment of different commercial aconitines, because Plugge experimented with all the varieties, and found them to vary in power, but not in quality of action. Those observers who have found least

influence upon the motor nerves acknowledge some *slight* effect, and that when aconitine is brought in contact with an exposed nerve it rapidly destroys its functional activity; also that after death in the aconitized frog the motor nerves lose their irritability more rapidly than normal (Liégeois and Hottot, Guillaud, S. Ringer and H. Murrell, Laborde and Duquesnel). Further, it has been noted that when in frogs the convulsions are very severe the motor nerves seem temporarily to lose their functional power from exhaustion (Mackenzie). Mackenzie affirms (*Practitioner*, xx. 186) that aconitine has a primary stimulant effect upon the motor nerve, and causes at first a distinct augmentation in the irritability both of nerve and of muscle.

According to Dr. Liégeois and M. Hottot (*loc. cit.*, p. 533), in aconito-poisoning loss of sensibility occurs in the frog's legs simultaneously with or even before the disturbances of respiration, and long before the power of voluntary motion is lost, and even when the reflex activity is intact. This sensory paralysis, according to the experiments of the French investigators just quoted, first appears in the hind legs of a frog poisoned with aconitine, and has not its primary seat either in the peripheral nerves or in the spinal cord, for it was found that tying the aorta close to its abdominal bifurcation, so as to prevent access of the blood—i.e., of the poison—to the posterior nerves, did not affect the development of the anæsthesia; further, that closing the artery nearer its origin in such a way as to shut off the circulation to the cord and spinal nerves, but to allow the passage of the blood to the cerebrum, did not cause sensory paralysis to come on more slowly than is normal in poisoning by aconite.

Of course it is possible for the peripheral ends of the sensory nerves to be paralyzed either at the same time that the perceptive centre is, or afterwards; and of course, the centre being paralyzed, it becomes very difficult to determine whether the periphery is or is not affected. Liégeois and Hottot assert that this paralysis of the centre occurs before any serious implication of the periphoric nerves, because after aconitic anæsthesia had been produced strychnine was able to induce tetanus; afterwards, however, the extreme periphoric nerves became affected, so that irritation of the skin in the doubly-poisoned frog would not provoke convulsions, even at a time when irritation of the trunk of a nerve would produce general reflex motor disturbance. At last galvanization of the nerve-trunk itself failed to induce response. From these facts Liégeois and Hottot deduce—very logically, I think—the conclusion that aconite induces anæsthesia by paralyzing, first, the perceptive centres; secondly, the peripheral extremities of the nerves; thirdly, the nerve-trunks themselves. The observers just named also confirmed this conclusion by other experiments than those already noticed. They found that although aconitine applied directly to a nerve-trunk paralyzes its sensibility, yet when the veins of a frog's leg are tied and the alkaloid injected into the artery and allowed to

permeates the tissues of the leg, the skin loses its sensibility long before the nerve is affected.

In regard to motion, Liégeois and Hottot found that in a certain stage of aconite-poisoning the frog lies with his limbs extended, relaxed, and perfectly paralyzed, and yet is capable of executing vigorous voluntary movements and evinces nearly normal reflex activity. They attribute this condition of apparent but not real motor paralysis to loss of sensibility from paralysis of the perceptive centre, as the unpoisoned frog evinces the same phenomena after division of all the posterior spinal roots. After a time the reflex activity is also lost, the power of voluntary movement remaining. Liégeois and Hottot believe that this loss of reflex activity is spinal; but in their experiments upon the conjoint action of aconite and strychnine it was found that at a certain stage, when no amount of irritation of a nerve would induce convulsions, a slight direct irritation of the cord would cause violent strychnic spasms. This would seem to show that at least the earliest abolition of the reflex activity was due to paralysis of the afferent nerve-fibres.

In some particulars the researches of Liégeois and Hottot have been confirmed by the later studies of Dr. George Hunter Mackenzie (*London Practitioner*, xx. 100). The persistence of voluntary movement after abolition of reflex actions, which was first noted by Boehm and Wartmann, and afterwards by Liégeois and Hottot, as well as by Mackenzie, proves that at a certain stage of the poisoning, while the motor pathway from the brain along the anterior columns and the efferent nerves is open, either the sensory nerves or the receptive centres of the cord are paralyzed. The experiments of Liégeois and Hottot upon the joint action of aconitine and strychnine are also accordant with those of Mackenzie, for that observer found that when a nerve was protected from the poison by tying its supplying artery, irritation of it caused reflex actions when the remainder of the frog's periphery was insensible; also that there is a stage of poisoning in which irritation of the extreme peripheral nerves fails to induce reflex movements, although such movements are called out by irritation of the sensory nerve-trunk; later irritation of the trunk was powerless, while irritation of the posterior columns of the cord still produced wide-spread movements. It must therefore be considered proved that aconite *paralyzes the sensory nerves, commencing at their peripheral endings*, and that the loss of reflex activity is due, at least in great part, to such cause.

The apparent contradiction between those investigators who have reached the conclusion just given and those who have found the motor nerves especially affected (see p. 412) can, it seems to me, be reconciled only by the theory that *aconitine acts upon the peripheral ends both of sensory and of motor nerves*: which nerve is most severely affected may possibly depend upon the size of the dose employed, or, more probably, upon the physical condition of the frog. The excessive numbness and

tingling of the local and general action of aconitine upon man indicate that in the higher animals it especially affects the sensory nerve-endings.*

The supposed action of aconitine upon a higher perceptive centre is at present very doubtful. S. Ringer and R. Murrell (*Journal of Physiology*, i., Nos. 4 and 5) deny the accuracy of the delicate experiments of Liégeois and Hottot. Curiously enough, Drs. Ringer and Murrell, while doubting the experiments of Liégeois and Hottot, accept the conclusions founded upon these assorted erroneous experiments, seemingly because they themselves have found that aconitine causes abolition of reflex action more rapidly in brainless than in normal frogs. It is evident that even if this were invariably the case it would in no way prove the conclusions of Liégeois and Hottot. Further, the experiments on brainless frogs were only three in number, and it is perfectly possible that the rapid reflex palsy was simply the result of batrachian idiosyncrasies. The only safe conclusion on the evidence is that the evidence does not warrant any conclusion.

It is evident that we have not exact knowledge as to how aconite affects the nerve-centres;† but the nervous phenomena of aconite-poisoning seem to me explainable by the action of the drug upon the sensitive and motor nerves.

Respiration.—The action of aconite upon the respiration is very decided. In mammals the respirations, under the influence of the drug, are slow, with a prolonged expiration following immediately upon the inspiration. After the expiration there is a long pause. The whole

* Laborde and Duquesnel (*Des Aconites*, Paris, 1893, p. 103) believe that they have demonstrated that aconitine does not act upon the sensory nerves. Their chief experiments consisted in tying the vessels of a dog's leg in such a way that no blood could return to the body, and injecting the alkaloid into the limb, after cutting the nerve. Under these circumstances they found that galvanization of the centric end of the nerve continued to elicit response. At most such experiments prove nothing as to the action of the poison upon the peripheral nerve-endings. Moreover, it remains uncertain whether the aconitine really came in contact with the divided nerve, as all circulation in the limb must have been arrested.

† Experiments by Mackenzie on frogs have yielded apparently contrary results to those of Boehm and Wartmann as to the effect of removal of the influence of Setchenow's centre upon the cord in aconitized frogs. The difference probably depends upon difference in the doses employed. Boehm and Wartmann distinctly state that when minute doses of aconitine are employed there is a primary period of excitement of the spinal centres. Mackenzie has found that the convulsions which are so severe in frogs after small quantities of aconite are chiefly of spinal origin, but that the peripheral motor apparatus shares the stimulation with the spinal motor tract. M. Guillaud (*loc. cit.*, p. 769) also affirms this primary stimulant spinal action. If it exists at all in mammals, it is in them completely masked. The convulsions seen in aconite poisoning in some mammals are cerebral, not spinal, as I have experimentally determined that they do not occur in those portions of the body separated by spinal section from cerebral influence.

As Boehm and Wartmann found that the reflex activity was lost more rapidly than the power of voluntary movement, and that no increase of reflex activity occurs in the aconitized frog when the cord is cut so as to release it from the influence of Setchenow's reflex inhibitory centres, they draw the conclusion that the aconitia first depresses the reflex activity of the sensitive spinal centres and afterwards that of the motor spinal centres, until the cord is completely paralyzed.

breathing-cycle resembles very much that occurring after section of the vagi, and, like the alteration in breathing after this section, seems to be due at least in part to paralysis of sensory or afferent fibres. The known influence of aconite upon the peripheral afferent nerves in general suggests that the poison disturbs respiration by paralyzing the peripheral afferent fibres of the vagi. Mackenzie states that in the aconitized animal section of the vagi produces no effect on the respiration; and Boehm and Wartmann (p. 127) affirm that aconite produces its usual effect after division of the nerves. It is plain that even if the aconite does paralyze the peripheral afferent vagi it must also act upon the respiratory centres, since arrest of respiration could not be caused by afferent palsy. As the arrest occurs in the frog before the motor nerves are affected by the poison, Liégeois and Hottot believe that the disturbance is centric; and I think there can be no doubt that *aconite is a direct depressant and paralyzant of the respiratory centres.**

Aconite lowers the bodily temperature in both man and the lower animals. Aechcharumow found in fatal poisoning a fall of about $3^{\circ}\text{C}.$ † The reduction of the bodily heat is probably caused by an increase of heat-dissipation. If vaso-motor paralysis occurs in aconite-poisoning it will account for this loss of heat. Further, it is entirely possible that aconite, without producing vaso-motor paralysis, may, by destroying the conducting power of the afferent nerves, put an end to the automatic relation between heat-production and heat-dissipation.‡ In accord with this is the observation of Brunton and Cash (*St. Barthol. Hosp. Rep.*, xxii., 1886) that in animals exposed to a high temperature, aconite, far from depressing the temperature, favors its increase, while when the animal is exposed to cold, aconite accelerates the fall of the bodily heat remarkably.

* Laborde and Duquesnel affirm that after very large doses of aconitine the animal dies of spasm of the glottis and diaphragm, because they have noticed, especially in the young animal, drawing in or constriction of the lower chest during life, and *sub-pleural ecchymoses* after death. These are, however, the marks of paralysis of the glottis from palsy of the recurrent laryngeal nerve.

† MM. Gréhaud and Duquesnel (*L'Union Pharm.*, Aug. 1871) have communicated to the French Academy some experiments upon frogs with *crystallized aconitine*, the results of which are so strikingly different from those of other experimenters as to indicate the existence of some fallacy: possibly the alkaloid used by them was not the same as the amorphous aconitine. They found in the frog, after small doses ($\frac{1}{10}$ milligramme) of their alkaloid, that the heart continued to beat steadily and regularly after all power of spontaneous or reflex movement had been lost, that sensation was preserved as long as any power of motion existed, and that the motor nerve-trunks were paralyzed. After large doses (one milligramme) they observed sudden arrest of the heart's action. These results are, however, entirely discordant with the later ones of Laborde and Duquesnel.

‡ Thus, in the normal animal, when heat-dissipation becomes excessive, contraction of the superficial blood vessels occurs, so as to prevent further loss of heat. If, by aconite, the afferent nerves carrying impulses to produce the reflex contractions of the superficial vessels are paralyzed, it is evident that these impulses cannot reach the centres to be returned to the vessels, so that regulation of the relation between heat-loss and heat-production would be impossible.

Summary.—Aconite seems to have little direct action upon the cerebral nerve-centres, but is a direct and powerful depressant to the respiratory centres. If it have any action upon the spinal cord, this action is subordinate to its influence upon the peripheral nerves and has not as yet been worked out. In sufficient dose it is a powerful depressant to the sensory nerves, its influence probably commencing at their peripheral endings and also affecting, though in less degree, the motor nerves. There is some reason for believing that the stage of nerve-paralysis is preceded by one of nerve-stimulation. The arterial pressure is always depressed by aconite in proportion to the dose, the fall of pressure being altogether or in chief part due to a direct depressing action upon the heart-muscle or the contained ganglia. Our knowledge of its influence upon the vaso-motor system is very imperfect, but the drift of the evidence suggests that it does not directly affect the vaso-motor centres, although, by paralyzing the afferent nerves, it may indirectly widen the blood-paths. Locally applied, it is a powerful paralyzant to the sensory nerves and also acts upon the motor nerves.

THERAPEUTICS.—Our knowledge of the physiological action of aconite, although imperfect, is sufficient to show that there are only two or three indications to meet which the drug may be used.

The first of these is to *lower arterial action*, and often, with it, excess of temperature. For this purpose aconite is very valuable. I have never used it in those cases, such as *pneumonia*, in which a sudden and very powerful effect is desired, simply because *veratrum viride* seemed to me safer, more readily controlled, and equally effective. Aconite may, however, be used with very good results in those cases, and especially in such diseases as *peritonitis*, in which it is very important to avoid vomiting. My own experience with it has been in *fevers* of a sthenic type not dependent upon so deep-seated a cause (as an example may be mentioned the *subtile movements* of severe *acute muscular rheumatism*), and in the *ephemera* or *irritative fevers* of childhood: in such cases its influence for good is often very decided. In the early stages of *scarlet fever* and other *exanthemata*, when not decidedly adynamic in type, it is very useful. In the reflex fever which sometimes follows the passage of the catheter or bougie (the so-called *urethral fever*) it is very efficient.*

In some cases of *hypertrophy of the heart*, when the valves are perfect, or when, the valves being diseased, the *hypertrophy* is greater than is necessary, aconite is of use to control cardiac excitement. When, however, there is dilatation of the heart or any degeneration of the heart-muscle, it is an exceedingly dangerous remedy, and it is at all times to be avoided if the *hypertrophy* be not excessive.

* The following formula affords an excellent combination: \mathcal{R} Tinct. aconiti rad., gt. i ; Sp. ætheris nitrosi, $\text{f}\mathcal{Z}\text{ij}$; Mist. potass. citrat., q. s. ad $\text{f}\mathcal{Z}\text{i}$. S.—Dessertspoonful every two hours for a child three years old.

A second indication which aconite might be used to fulfil is to *allay spasm*. As, however, its influence upon the motor centres and nerves is much less than upon the sensitive centres and nerves and upon the heart, the indication is better met by other remedies.

A third indication, which it would seem from its known physiological action that aconite should meet, is to *relieve over-excitation of the sensitive nerves*. Clinical experience has confirmed this. As long ago as 1834, Dr. Turnbull (*On the Preparations and Medical Employment of Aconitina by the Endermic Method*, London, 1834,—*On the Medical Properties of the Natural Order Ranunculaceæ*, London, 1835) called attention to the use of the alkaloid in *neuralgia*; and his estimate of its value has been confirmed by Dr. A. Fleming (*An Inquiry into the Physiological and Medicinal Properties of the Aconitum Napellus*, Edinburgh, 1845) and by other observers.

In cases of *rheumatic neuralgia* dependent upon an acute exposure to cold and attended with more or less febrile disturbance, in combination with other suitable remedies aconite is often of great service. In *chronic neuralgia*, associated as it always is with a lowered systemic tone, the remedy is less efficient; yet in some cases it seems to give relief. Owing to its very marked local benumbing influence, applied to the painful part it is sometimes very useful. In my own experience, this local use of it has, however, very seldom been effective when, as in *migraine*, the pain is of centric rather than of peripheral origin.

Given in full doses in the reflex vomiting of *pregnancy*, aconite is often advantageous, acting probably by benumbing the sensory reflex centres, or possibly the afferent peripheral nerves. I have noticed that relief lasts only so long as decided constitutional effects from the drug are apparent.

Toxicology.—Aconite is an exceedingly powerful poison; one-twelfth of a grain of the crystallized alkaloid is, according to Duquesnel, sufficient to kill a rabbit in a short time. Five grains of an extract and eighty minims of a tincture are said to have caused death (Reichert, *Phila. Med. Times*, Nov. 1881, p. 105). The symptoms usually come on in a very few minutes. In the shortest case I have met with, death occurred in thirty minutes. The average time of death (Reichert, *loc. cit.*) is three and a third hours; the longest recorded case being five and a half hours.

The *aconitines* of commerce vary inordinately in strength, so that while one-sixteenth of a grain (prepared by Petit,* of Paris) caused

* In the researches of Anrep, Duquesnel's crystallized aconitine was nearly twice as strong as a German alkaloid used by him, which in turn was much stronger than an English article. Plugge found Petit's aconitine eight times as strong as that of E. Merck. Langgaard found an alkaloid prepared from *A. japonicum* exceedingly powerful. The best discussions of the relative strength of these alkaloids that I know of may be found in *Schmidt's Jahrb.*, ccli. 124, and in *Des Aconite*, by Drs. J. V. Laborde and H. Duquesnel, Paris, 1883. Lbôte

the death of Dr. Carl Meyer in five hours, several grains of the impure article so largely sold have been recovered from. The symptoms have been in general those of aconite-poisoning, but excessively violent pains and convulsions have been very marked features of some of the cases. (For discussion of aconitine-poisoning, see Dr. Thomas Stevenson, *Guy's Hospital Reports*, 3d series, xxvi. 308; M. Jules Bassot, *Lyon Thesis*, No. 479, 1889; also, six cases, Lhôte and Vibert, *Annal. d'Hyg. Publ.*, Avril, 1892.)

The only diagnostic symptom of aconite-poisoning is the peculiar tingling, which is probably always present, though in suicidal cases the patient may refuse to reveal it, or in advanced poisoning unconsciousness may prevent its being told. The presence in any case of poisoning of absolute prostration with almost complete failure of the pulse, great muscular relaxation, and other symptoms of collapse, without vomiting, purging, or any disorder of the pupil or other toxic manifestations, should always excite suspicion.

The first indication for treatment in aconite-poisoning is evacuation of the stomach; as emetics usually fail, on account of the local gastric anæsthesia, the stomach-pump may often be used, but the danger of causing fatal collapse in extreme cases must not be overlooked. Tannic acid may be administered as an imperfect antidote. Hot concentrated alcoholic stimulants should be freely given; strychnine, cocaine, and digitalis* should be used hypodermically with great boldness, tempered with caution. Ammonia may be injected into the veins, if it be found practicable. The patient must be kept upon the back, with the feet a little higher than the head, and external heat be used when the temperature becomes subnormal. Laborde and Duquesnel affirm that in

and Vibert (*Annal. d'Hyg. Publ.*, tome xxviii., 1892) claim that the crystallised aconitine of Duquesnel is an essentially different poison from the amorphous aconitine of commerce or from the sulphate of aconitine of Merck. The latter in the isolated frog's heart they found to produce gradual progressive enfeeblement, whilst the Duquesnel aconitine caused primarily great increase in the size of the cardiac pulsation, with periods of ataxia, followed by depression.

* It was discovered by Dr. J. Milner Fothergill (*Digitalis*, London, 1871, p. 61) that in the aconitised frog, even when cardiac action has ceased, digitalis has power to recall the systolic movements. More recently this antagonistic action of aconite and digitalis upon the frog's heart has been abundantly proved by various experimentalists. Clinical experience, although still limited in extent, strongly corroborates the experimental evidence of the value of digitalis. Successful cases may be found in *Brit. Med. Journ.*, Dec. 11, 1872 (Æ Fleming's tincture, Tinct. digitalis ℥ x hypodermically); *Bost. Med. and Surg. Journ.*, Oct. 1879, 546 (Æ Tinct. aconit. rad., Tinct. digitalis ℥ lx hypodermically); *Indian Med. Gaz.*, xvii. 323 (Aconitum serot root 48 grains, Tinct. digitalis ℥ xxv hypodermically and Æ by mouth); *Phila. Med. Times*, xlii. 328 (a decoction of aconite, amount unknown, Tinct. digitalis in drachm and half-drachm doses, by mouth). In a successful case treated by Dr. Elliot (*Lancet*, 1878, ii. 917) nitrite of amyl freely inhaled seemed to do great good: a fluidounce of a concentrated aconite liniment was thought to have been taken. Ammonia injections were unsuccessful in a case reported in the *Austrian Med. Journ.*, 1879, i. 283. Dr. U. H. Tuttle (*Boston Med. and Surg. Journ.*, cxxv., 1891) has reported recovery after seven and a half drachms of the tincture, under the free hypodermic use of brandy and digitalis, the same remedies with tincture of nux vomica being given internally, and auxiliary measures used.

the lower animals death after a usually fatal dose of aconitine can be prevented by artificial respiration; and in a case of human poisoning, if the heart's action were at all sustained, and the respiration failing, Silvester's method or forced artificial respiration might be resorted to.

ADMINISTRATION.—Aconite is never used in substance. The dose of the *tincture of aconite* (*Tinctura Aconiti*—35 per cent., U.S.) is one to five drops, repeated every one to three hours *pro re nata*, its effects being always watched. *Fleming's tincture* is a stronger preparation ($\frac{3}{4}$ ss to Oj). The dose of the *extract* (*Extractum Aconiti*, U.S.) is one-quarter to three-quarters of a grain; of the *fluid extract* (*Extractum Aconiti Fluidum*, U.S.), one to two minims. The tincture or the fluid extract of aconite is very frequently added to stimulating and anodyne liniments.

Aconitine is not officinal, and, on account of its intense activity, should not be given internally: one-quarter of a milligramme has caused very serious poisoning (*Schmidt's Jahrb.*, Bd. cexxxvi., p. 125). Even the external use of the alkaloid requires great care. The ointment may be of the strength of one grain to the drachm: a two-per-cent. solution of the oleate of aconitine in oil has been highly commended as a local application in neuralgia.

ACIDUM HYDROCYANICUM—HYDROCYANIC ACID.

Pure hydrocyanic acid is a colorless, transparent, volatile, inflammable liquid, giving rise to giddiness and headache when smelled, and having, it is said, a burning, bitter taste. So poisonous is it that when inhaled it causes death, and it must be handled with the greatest caution: smelling and tasting it are excessively dangerous proceedings. It is, indeed, an imperative rule that no one should experiment with anhydrous prussic acid alone, or under any circumstances in summer, or in a warm room, or in an apartment whose open windows and doors do not admit of a free draught of air. The chemist Scheele, the discoverer of prussic acid, is believed to have been killed by the inhalation of the fumes of this material, whose poisonous properties were first pointed out by the Berlin apothecary Schrader in 1803. The anhydrous acid is soluble in water and in alcohol, but is never kept in the shops, and is not officinal.

Hydrocyanic acid of common medical parlance is the officinal *Dilute Hydrocyanic Acid* (*Acidum Hydrocyanicum Dilutum*, U.S.), a colorless, watery solution, containing two per cent. of the anhydrous acid. Its odor and taste are the familiar ones of peach-kernels and bitter almonds; its reaction is faintly acid. According to the directions of the U.S. Pharmacopœia, it is prepared by distilling a mixture of ferrocyanide of potassium, sulphuric acid, and water, or by precipitating cyanide of silver from its watery solution with hydrochloric acid. With solution of nitrate of silver added in slight excess, one hundred grains of it produce a white precipitate, which, when washed with water until the

washings are tasteless, and dried at a temperature not exceeding 212° , weighs ten grains, and is wholly soluble in boiling nitric acid.

The precipitate in this case is the cyanide of silver, and the amount afforded shows that the liquid contains the officinal percentage of anhydrous prussic acid.

As hydrocyanic acid has a great tendency to undergo spontaneous decomposition, especially under the influence of light, it should be kept in well-stopped, dark-colored bottles.

PHYSIOLOGICAL ACTION.—In warm-blooded animals, poisoning by hydrocyanic acid divides itself naturally into the acute and the sub-acute.—death occurring in the first in at furthest ten minutes, in the second not at all, or else only after the lapse of a longer time than that noted. After a full dose of the strong anhydrous acid, the animal gasps once or twice, and then instantly falls in a tetanic or clonic convulsion, or else drops motionless and powerless upon its side. In either case, at once the signs of asphyxia manifest themselves, and grow more and more intense, until they end in total arrest of respiration. The heart beats irregularly, often at first slowly and strongly, with intervals of suspension of movement, but always becoming weaker and more rapid in its action, until, after the breathing has ceased, its efforts gradually die away. If the dose has been enormous, the heart and lungs may stop acting at once; otherwise the cardiac pulsations may continue some minutes after the arrest of respiration. Ordinarily, three distinct stages are apparent: a first, very brief one, of difficult respiration, slow cardiac action, and disturbed cerebration; a second, convulsive stage, with dilated pupils, violent convulsions, unconsciousness, loud cries, vomiting, often spasmodic urination and defecation, erections, etc.; and a third period, of asphyxia, collapse, and paralysis, sometimes interrupted by partial or even general spasms.

The slow form of the poisoning follows the exhibition of the poison in an amount just sufficient to kill. After the ingestion of such a dose, no phenomena are offered for some seconds; then the breathing becomes labored, and the pulse slow and full. The animal perhaps cries out, and muscular tremblings invade the whole body, to give place, in a very short time, to clonic and tonic convulsions, which continue at intervals until the third stage, that of collapse, is developed. The convulsions are less violent and less frequent than those of the acute poisoning; all the symptoms noted as occurring during the second stage of rapid cases are present in the corresponding period of the subacute poisoning, although less violent and less intense in their manifestations. When the third stage is developed, the anesthesia is marked, affecting first the hind legs, but finally spreading to all parts of the body, and even being complete in the widely-dilated pupil. Death finally results from failure of respiration. Recovery may occur even after the conjunctiva has lost its sensibility; the return to life by a subsidence of the symptoms is usually rapid, so that generally in from one-half to

three-quarters of an hour the animal will be eating as though nothing had happened. Coullon, however, noted persistence of paralysis, in some cases, for days.

In man, prussic acid produces results closely parallel with those which it causes in the lower animals. The symptoms come on suddenly. In a moment or two the individual falls to the ground insensible and convulsed, the respirations arrested or occurring at long intervals, the eyes salient, the pupil dilated, the mouth covered with bloody froth. If the dose be sufficiently large, death may occur in three or four minutes; if less has been taken, deep insensibility, tetanic or clonic convulsions, dilated pupils, a bloated countenance, cyanosed surface, set jaws, and irregular respiration, constitute the chief symptoms. The breathing is mostly convulsive, with deep, forcible expirations, but in some cases it has been stertorous. Death results from asphyxia. After small toxic but not lethal doses of prussic acid, giddiness, lightness of the head, nausea, a quick pulse, and muscular weakness are the chief symptoms.

Action on the Blood.—As early as 1814, Dr. F. B. Vietz (*Med. Jahrb. d. k. k. Oesterreich. Staates*, Bd. ii., 1814) called attention to the change of color that occurs in the venous blood of animals poisoned with prussic acid; and his observations have been confirmed by E. L. Schubarth (*Horn's Archiv f. Med. Erfahrung*, Berlin, 1824), by J. F. Sobernheim (*Handbuch der Prakt. Toxicologie*, Berlin, 1838), and by Dr. Coze (*Gazette Médicale de Paris*, 1849). In his *Leçons sur les Substances toxiques*, p. 193 (Paris, 1857), Claude Bernard reaffirms the occurrence of these changes, and further states that if the animal dies suddenly the blood in the veins and right heart is found of a bright arterial hue at the post-mortem. Notwithstanding all this testimony, J. R. Bischoff (*Ueber Vergiftungen nebst einigen Versuchen an Thieren, welche mit Blausäure*, etc., Wien, 1844) and numerous other observers have found that after death from prussic acid, either in man or in other mammals, nothing but dark venous blood exists in the body. Of the correctness of this observation there can be no doubt.

Professor W. Preyer (*Die Blausäure*, Bonn, 1870) has afforded by his experiments an explanation of these apparently contradictory facts. He found that directly after the exhibition of prussic acid to a mammal the blood becomes, even in the veins and in the right heart, of a bright arterial hue, but that after a time this color darkens into the blue of venous blood, and finally, even in the arteries and in the left ventricle, only blood of such character is to be found. Dr. Carl Gaethgens (*Hoppe-Seyler's Medicin.-chem. Untersuchungen*, Berlin, 1866, p. 324) has, in a number of experiments, confirmed this, so it must be accepted as a fact. When an animal dies suddenly from cardiac paralysis, during the first stage of poisoning, this excessive arterialization may be found after death, as mentioned by Claude Bernard; and, as Preyer first noticed, in cold-blooded animals the bright color persists for many

hours. By spectroscopic examination Professor Preyer (*loc. cit.*, p. 95) found that the dark blood of prussic acid poisoning is absolutely or almost free from oxygen, showing only the absorption bands of deoxidized hæmoglobin, while Gaethgens (*loc. cit.*, p. 328) has discovered that the red venous blood of the first stage of the poisoning shows very clearly the absorption bands of oxyhæmoglobin. The first question which arises at this juncture is as to the causes of these changes of the blood, its primary excessive arterialization, its secondary excessive carbonization. Professor Hoppe-Seyler affirms (*Medicin.-chem. Untersuchungen*, p. 140, Berlin, 1867) that the appearance of red blood in the veins is because the red blood-corpuscles have been so acted upon by the poison as to have lost their ability of yielding up their oxygen in the capillaries. Dr. Carl Gaethgens (*Ibid.*, p. 325) has by an elaborate series of experiments shown that in the first stage of prussic acid poisoning much less than the normal amount both of carbonic acid and of exhaled oxygen is eliminated. The lessened exhalation of oxygen probably depends simply upon a lessened inhalation of oxygen, owing to the disordered respiration. That the lessened excretion of carbonic acid is not due to the same cause, however, is shown by the fact, determined by Gaethgens (*loc. cit.*, p. 347), that the percentage of the acid in the expired air is less than normal, while that of oxygen is greater than normal. It is evident that if the lessened excretion of carbonic acid were produced by the entrance into the lungs of an amount of air insufficient for the wants of the system, the expired air would contain more than its normal proportion of carbonic acid and less than its normal amount of oxygen. The observed phenomena seem to me to prove that during the first stage of prussic acid poisoning oxidation is arrested. They do not demonstrate, however, that the arrest is due to a direct action of the poison upon the blood-corpuscles. The probabilities of such occurrence are rendered very slight by the investigations of Gaethgens himself, for he found that when the experiments were prolonged from seventeen to forty-four minutes, much more than the normal amount of carbonic acid was exhaled, a fact in accord with the excessive carbonization of the blood known to take place in protracted hydrocyanic acid poisoning. As it seems incredible that a substance should one minute paralyze the ozonizing power of the blood-corpuscles and the next minute increase it, it is very improbable that the super-arterialization of the blood in the first stage of prussic acid poisoning is due to a direct action of the poison upon the red disk.

Preyer has proved (*loc. cit.*, p. 85) that when to blood at the temperature of the body hydrocyanic acid is added, the spectrum after a time is altered and new absorption bands appear. These bands are due to the formation of a new compound by the union of the hæmoglobin and the hydrocyanic acid. This substance, *cyanohæmoglobin*, was first discovered by Hoppe-Seyler (*Virchow's Archiv*, Bd. xxxviii. p. 475),

and has no ozonizing power whatever; to its formation, no doubt, is owing the loss of ozonizing power by blood to which hydrocyanic acid is added outside of the body, a phenomenon pointed out by Schönbein* (*Schmidt's Jahrbücher*, 1868, Bd. cxi. p. 161), and indicated even earlier by the researches of Professor Harley (*Lond. Phil. Trans.*, 1865, p. 706).† The latter observer found that the blood taken out of the veins of a subject forty-eight hours after death from prussic acid poisoning, and thoroughly arterialized by shaking with air, and then allowed to stand, yielded gas containing 19.56 parts of oxygen, 80.14 parts of nitrogen, and 0.00 parts of carbonic acid.

These facts at first sight seem to prove the theory of Hoppe-Seyler, to which indeed they no doubt gave origin. Preyer has shown (*loc. cit.*, p. 95), however, that the dark blood of prussic acid poisoning has not lost its power of oxidization, for on being shaken with the air it assumes the red arterial hue; and Drs. Locorehé and Meuriot (*Archives Gén.*, 6e série, t. xi. p. 539) have determined that artificial respiration will produce the same result in the poisoned animal. Moreover, the spectroscope shows plainly that the hæmoglobin exists in the blood either in its pure state (Preyer, *loc. cit.*, p. 95) or else as oxyhæmoglobin (W. Laschkewitsch, *Reichert's Archiv*, p. 652, 1868; Hiller and Wagner, *Lancet*, 1877, vol. ii. p. 933), and that no cyanohæmoglobin is present. The reaction between hydrocyanic acid and hæmoglobin is one requiring some time, and evidently does not occur in poisoning. On the whole, therefore, I think that the chemical evidence clearly shows the falsity of the theory that prussic acid acts in the body directly upon the red blood-corpuscles.

Preyer (*loc. cit.*, Theil ii. p. 88) has shown that the excessive oxygenation and the subsequent excessive carbonization of the blood are not peculiar to hydrocyanic acid poisoning, but are equally present after the exhibition of sulphuretted hydrogen, and even after mechanical closure of the mouth and nose. It is possible that an increased arterial pressure, an increased rapidity of circulation, may cause the blood to pass too quickly through the capillaries to allow time for the usual changes; but this has not been proved, and at present it must be

* In the same memoir Schönbein calls attention to the fact that hydrocyanic acid destroys also the ozonizing power of living vegetables, such as roots, fungi, etc.

† According to Dr. E. Ray Lankester (*Pflüger's Archiv*, 1869, p. 492), when blood is shaken with cyanogen gas, and allowed to stand for two or three hours, the spectrum changes are exactly the same as after similar treatment of blood with CO. The compound of cyanogen and hæmatin (Cy,Hb) offers not only the identical spectrum of CO,Hb, but also, like the latter, is unaffected by reducing agents. After the blood stands awhile, according to Dr. Lankester, the spectrum of hydrocyanic acid (H,CN) becomes visible in it, and the Cy,Hb undergoes conversion into the cyanohæmoglobin (Cy,Hb) of Hoppe-Seyler.

Any one desirous of investigating this subject more deeply than can be done in a work like the present should consult especially the papers by Hoppe-Seyler, *Virchow's Archiv*, Bd. xixviii., and scattered through the *Med.-chem. Untersuchungen*; by Harley, *Lond. Phil. Trans.*, 1865, p. 706; and by Preyer, *Pflüger's Archiv*, 1869, p. 395.

acknowledged that we are ignorant as to the immediate cause of the blood-changes in these cases.

It is possible, although scarcely probable, that the changes in the color of the blood are due to alteration in the form of the corpuscles. According to Ernst Geinitz (*Pflüger's Archiv*, 1870, Bd. iii. p. 46), outside of the body prussic acid produces in the blood-corpuscles of the frog, first, a shortening of the long and a lengthening of the short diameter, and consequently a rounded form, then granulations, and finally a solution and setting free of the nucleus. In frogs poisoned with prussic acid a rounded form of the corpuscles was commonly exhibited, and sometimes granulations were present. M. Geinitz also found that the red disks of mammalian blood, exposed to the vapor of hydrocyanic acid in the moist chamber of Stricker, become first somewhat asymmetrical, then mulberry-shaped, and finally undergo molecular destruction. In poisoning of mammals, according to the same investigator, the granular blood-corpuscles are commonly met with. Preyer (*loc. cit.*, Theil ii. p. 91) confirms the observation of Geinitz so far as the action of the poison upon drawn blood is concerned, but both he and Hünefeld (*Der Chemismus in der thierischen Organisation*, Leipzig, 1840) assert that immediately after death from prussic acid the corpuscles offer their usual characters.

Whatever may be the cause of the changes in the blood, the experiments of Lewissou (*Reichert's Archiv*, 1870, p. 352) would appear to prove that the action of the poison on the nervous system is a direct one, and not due to these changes in the vital fluid, for the observer mentioned found that prussic acid acted upon the bloodless "salt frog" as upon the normal batrachian.

Action on the Heart.—The action of hydrocyanic acid upon the heart varies according to the dose. In sufficient amount and concentration it produces instantaneous diastolic arrest, which is either permanent or reoccurs after a few slow feeble beats (Preyer, *loc. cit.*, p. 52, and Drs. Lacorché and Meuriot, *Archives Gén.*, 6e série, t. xi. p. 513). As early as 1826, Krimer found that prussic acid placed directly upon the heart of the frog produces arrest of its beat and loss of its muscular irritability. Preyer has confirmed this, and it would seem to be proved that the cardiac arrest spoken of above is due to a direct action upon the heart-muscle or its contained ganglia, yet that after cardiac death from prussic acid the heart responds to galvanism.

The cardiac results of the exhibition of small non-toxic doses are, according to Preyer, simply slowing of the heart's action.

Preyer and Laschkewitsch agree as to the action of large, but not enormous, doses. At first there is a sudden prolonged diastolic arrest of the heart, followed by an augmentation in the rapidity of the cardiac action, and after this a diminution of the rate,—to the normal number in cases of recovery, to cardiac stand-still in cases of death. Both

Preyer* and Laschkewitsch (*Reichert's Archiv*, 1868, p. 653) found that after section of the vagi the primary diastolic arrest of the heart did not occur. The recent investigations of Jos. Lazarski confirm the statements of Preyer as to the action upon the vagus. A complete inhibitory arrest of the heart was rarely achieved, yet slowing of the pulse was constantly produced by moderate doses of the poison in the normal animal, but was prevented by previous section of the vagi, and was removed, when present, by division of the inhibitory nerves (*Wien. Med. Jahrb.*, 1881, 141). It would seem, therefore, proved that small doses of prussic acid stimulate the cardiac inhibitory nervous centres. Boehm and Knie noted that large doses of the acid caused slowing of the pulse whether the vagi were cut or not (*Archiv für Exper. Path. and Therap.*, ii. 137), and in this have been confirmed by Lazarski. This slowing would seem to be due to a direct action upon the muscle or the intra-cardiac ganglia, as Lazarski found that the cardiac accelerator nerves are not paralyzed.

Moderate doses of prussic acid seem to produce a primary very brief but great rise in the arterial pressure, followed by a fall to or below the normal. This primary rise has been noticed by Boehm and Knie, by Wahl (*De Vi et Effectu Hydrocyanato ad Curationem attrib.*, Bonn, 1865), by Rossbach and Papitzky (*Centralbl. f. Med. Wissens.*, 1877, p. 640), and by Lazarski. It does not seem to be altogether the result of the asphyxia produced by the acid, as it is recorded by Boehm and Knie (*loc. cit.*, p. 146) as occurring when artificial respiration was used, and Lazarski has confirmed this. All observers agree that it is followed, if the dose of the poison has been large enough, by a profound sinking of the arterial pressure. Lazarski found that galvanization of a sensitive nerve has no effect at this time upon the blood-pressure: so that we must consider that hydrocyanic acid primarily stimulates very briefly the vaso-motor system directly or indirectly, and afterwards paralyzes it.

Action on Respiration.—According to Preyer (*loc. cit.*, pp. 17, 18, 19), during all three stages of hydrocyanic acid poisoning the respirations are lessened in frequency, and during the latter moments of life the efforts at breathing are very distant, and finally cease before the arrest of cardiac movements. The observer just mentioned found that, after division of the vagi, normally lethal doses did not kill, and that when death was brought about by the exhibition of larger doses it was by cardiac arrest. From this he deduces the conclusion that the prime respiratory action of the poison is upon the peripheral ends of the vagi. Dr. Preyer's experiments have been partially confirmed by Drs. Lecorché and Meuriot (*loc. cit.*, p. 538); but Boehm and Knie (*Archiv f. Exper. Path. u. Therap.*, Bd. ii. p. 135) have in a series of experiments found that section of the vagus has no influence upon the respiratory action

* Preyer (*loc. cit.*, p. 93) has also noted the same absence in curarised animals poisoned by hydrocyanic acid.

of the poison, and in this have been confirmed by Jos. Lazarski (*loc. cit.*). Even if investigations had proved the correctness of Preyer's experiments, his conclusion could not be considered established, because we know so imperfectly the normal relations of the pneumogastries to respiration. Moreover, Professor Joseph Jones (*New York Med. Record*, vol. ii. p. 459) found that while to kill an alligator by the administration of prussic acid required a considerable length of time, its application to the medulla produced within one minute a most powerful expiration, ending in permanent contraction of the muscles of respiration and collapse of the lung. We must, it seems to me, at present consider that the respiratory phenomena of prussic acid poisoning are due to an influence exerted directly upon the respiratory centro.

Action on Muscles and Nerves and Nerve-centres.—Dr. Kölliker (*Virchow's Archiv*, Bd. x. p. 272) has found that in frogs dead of prussic acid poisoning both the nerve-trunks and the muscles are unexcitable, or that the muscles respond very feebly to direct stimulation. This is in accord with the experiments of Stannius (*Reichert's Archiv*, 1858, p. 95), who found that when strychnine and prussic acid were given together, the convulsions normally produced by the former poison were altogether absent, or present only in a slight degree. In order to determine whether the nerves are or are not primarily affected, Kölliker experimented by tying the vessels of the thigh, then dividing just below this point all the tissues except the nerve, and administering prussic acid by the mouth. In a number of such experiments he found that always the nerve and muscles below the point of section retained their irritability, but that when the galvanic or other stimuli were applied to the nerve higher up, they failed to elicit any response from the unpoisoned tributary muscles,—positive proof that the nerve-trunks are paralyzed by a direct action of the drug. This is seemingly opposed to the experiments of Stannius (*loc. cit.*), who concluded that prussic acid applied locally to the nerves has no effect upon them. Stannius, however, compared the results of soaking a nerve in water and in a weak solution (three to four per cent.) of prussic acid, and found that water thus employed is toxic to the nerve-trunks. Kölliker used, in repeating the experiments of Stannius, neutral solutions of phosphate of sodium, one containing, the other free from, hydrocyanic acid, and found that the nerves in the poisoned liquid died much sooner than did those in the non-poisoned solution.

The experiments of Kölliker are in agreement with those of Stannius, that the muscle dies very much more quickly in the solution of the acid than does the nerve, losing its excitability in from seven to eight minutes. This rapid destruction of muscular irritability by the local application of prussic acid was, I believe, first noted by Coullon in 1819. Yet it is most probable that when given internally prussic acid acts almost as rapidly upon the nerve-trunks as upon the muscles, since Kölliker noted that in some cases galvanization of the nerve was

incapable of causing contractions in the tributary muscles, although the latter responded feebly to direct stimulation. This fact has been experimentally corroborated by Funke (*Berichte über die Verhandl. d. k. sachs. Gesellschaft d. Wissensch. zu Leipzig*, 1859, Bd. xi. p. 28).

Upon the peripheral sensitive nerves prussic acid probably, if in sufficient concentration, acts as a paralyzant; at least Kolliker (*loc. cit.*, p. 282) found that if the leg of a strychnized frog, whose heart had been cut out to prevent absorption, was put in a four-per-cent. solution of prussic acid, in a very short time irritation of the immersed skin ceased to produce convulsions.

From the slowness with which, in Kolliker's experiments, the nerve-trunks were affected in frogs poisoned by hydrocyanic acid, it seems probable that he is correct in his conclusion that in these batrachians the poison first paralyzes the brain, then the reflex centres of the spinal cord, and afterwards the motor nerves. But I have not met with any experimental evidence in regard to the order in which prussic acid affects the nervous system. According to Kiedrowski,* as quoted by Preyer, in frogs it first paralyzes the gray, then the white substance of the brain, and the early disappearance of reflex movements is not due to spinal palsy, but to destruction of the functional power of the peripheral afferent nerves. Preyer also states that the conclusions of Kiedrowski rested upon the following experimentally-proved fact, which, if accurate, seemingly renders them logically inevitable. When a frog is poisoned with prussic acid, and afterwards with strychnine in properly-proportioned doses, there is a stage at which slight irritation of the afferent nerve-roots causes violent general tetanic spasms, although the most intense peripheral irritation fails to elicit response.

It is a question of interest to decide as to the cause of the convulsions in poisoning by hydrocyanic acid. I have found that they do not occur after section of the cord in parts below the point of section, and that they are therefore cerebral in origin: for reasons detailed elsewhere (see p. 384), it is very probable that they are due to disturbed cerebral circulation, and this probability is confirmed by an experiment of Laachkewitsch (*Reichert's Archiv*, 1868), who opened the thorax of a rabbit so as to expose the heart, maintained artificial respiration, and administered prussic acid; directly after arrest of the heart had commenced, the convulsion came on. The earlier observation of Coze (*Comptes-Rendus*, 1849, t. xxviii. p. 780) is also to the same effect, as he states that the convulsions did not occur until directly after the arrest of the circulation. In frogs poisoned with hydrocyanic acid, convulsions do not take place. Preyer states that after section of the vagi

* I have, unfortunately, been unable to obtain access to the original paper of E. de Kiedrowski. Even Preyer appears to know it only in abstract. According to him, it was published in 1858, at Breslau, as a dissertation, under the following title: *De quibusdam experimentis quibus quantum vim habeat acidum hydrocyanicum in nervorum systema cerebro-spinale atque in musculos systematis vertebralis probatur.*

convulsions do not generally happen in mammals, but if artificial respiration be performed they come on (*loc. cit.*, p. 69).

Summary.—When in sufficient concentration hydrocyanic acid is a powerful depressant poison to all the higher tissues. In poisoning by it death usually occurs through centric paralysis of the respiration, but the depression of the heart's action is pronounced, and diastolic cardiac arrest sometimes takes place simultaneously with or even before cessation of breathing. Upon the nerve-centres it has a most pronounced depressing influence, and it is also a paralyzant to the nerve-trunks and to the muscles themselves. There is some reason for suspecting that after the small toxic dose of hydrocyanic acid the paralytic stage is preceded by a very brief stage of excitement, with centric increase of the respiratory activity, rise of the arterial pressure (caused by an influence upon the vaso-motor centres and perhaps upon the heart), and slowing of the pulse from stimulation of the cardiac inhibitory centres. Outside of the body hydrocyanic acid attacks the red blood-corpuscles, forming a new compound, cyano-hæmoglobin; but the occurrence of this change during life in hydrocyanic acid poisoning is doubtful.

THERAPEUTICS.—Our knowledge of the physiological action of prussic acid does not lead to a belief in its wide applicability to the relief of disease, and I think clinical experience has demonstrated that it is of little value except in meeting three indications: first, to *allay cough*; second, to *relieve irritation of the gastric nerves*; third, to *allay irritation of the peripheral sensitive nerves*.

There appears to be in the profession a very wide-spread belief in the power of this remedy to allay cough; at least it is very largely used for this purpose in cough-mixtures, either itself or in the form of cyanide of potassium. I have employed it in a great number of cases in hospital practice, and apparently with good effect, although, as it was always given in combination with such remedies as morphine, it is difficult to say how much of the result was due to it. I do not believe it can compare with such narcotics as opium or hyoscyamus in its ability to fulfil the present indication.

There can be, on the other hand, no doubt as to the value of prussic acid in certain stomacic affections, especially nervous vomiting and *gastralgia*. When the pain is accompanied by decided dyspeptic symptoms, the remedy will sometimes succeed, but more often fails. Even in the most favorable cases it does not always afford relief; and as the relief when it does occur is immediate, or at least is very soon apparent, it is useless to persist long in the exhibition of the remedy. In these cases its action is probably local, as it certainly is when the acid is employed to relieve itching in *prurigo* and other cutaneous diseases. For this purpose it is used as a wash (f3ss to f3i in f3i); but great care must be taken to avoid constitutional effects, especially when there is any abrasion of the skin. Very serious results are said to have been caused by its absorption when carelessly used in skin-diseases.

Prussic acid has been commended as an arterial sedative; but it is evident that we possess numerous more efficient and far safer remedies of such character.

TOXICOLOGY.—The symptoms of prussic acid poisoning have already been mentioned: those of most value from a diagnostic point of view are the sudden occurrence of unconsciousness; the violent convulsions; the general paralysis; the peculiar character of the breathing, expiration being prolonged and forced; and the rapid results. The odor of prussic acid upon the breath is very often, but by no means always, present. When distinct, it is, of course, of very great diagnostic value. Leaving out of sight the cyanides, the only poison with which prussic acid could well be clinically confounded is nitro-benzole. The distinction is often very difficult, large doses of the latter substance killing almost as quickly as prussic acid, and inducing analogous symptoms. Caspar advises that after death the body be left open, exposed to the air, as the odor of prussic acid disappears rapidly, while that of nitro-benzole is persistent. The diseases with which the poisoning may be confounded most readily are some forms of *apoplexie foudroyante*, and sudden failure of the heart's action. The diagnosis may, during life, be almost impossible. It has been asserted that stertorous breathing does not occur in prussic acid poisoning; but it has been present in several reported cases. (See *Taylor's Medical Jurisprudence*, Philadelphia, 1873, p. 363.) An autopsy, however, ought generally to enable the physician to determine whether the case has or has not been one of prussic acid poisoning, if the symptoms during life are known.

A curious case of temporary *hemipia*, apparently caused by the fumes of hydrocyanic acid, is reported in *Brit. Med. Journ.*, 1884, i. 409.

The period at which death may occur after the ingestion of the poison is set down by Lonsdale at from one to fifty-five minutes; but a case is reported in *Guy's Hospital Reports*, 1868, p. 259, observed by Dr. Hilton Fagge, in which the fatal result was put off for at least an hour and a quarter after the ingestion of hydrocyanic acid. After death the body often presents a livid surface, bloated countenance, fixed glassy eyes with dilated pupils, and clinched fingers; sometimes it offers nothing worthy of note except excessive rigidity, and the face may be very pale. When opened, the odor of prussic acid is generally, but not always, emitted; the mucous membrane of the stomach is very commonly found much congested, and the dark or cherry-colored liquid blood usually everywhere fills up the veins. The heart is soft and flaccid.

The treatment of poisoning by prussic acid is, unfortunately, as inefficient as it is simple. There is no known chemical or physiological antidote to it, the asserted antagonism of atropine having been disproved by the experiments of Keen (*Proc. Phil. Acad. Nat. Sci.*, 1869) and of Boehm and Knie. The stomach should, if possible, be emptied, and the hypodermic use of atropine as a respiratory stimulant might be

tried; the inhalation of the vapors of ammonia, and the free exhibition of ammonia by the mouth and by injection into the veins, may be practised. Artificial respiration has been found very successful by Preyer, and by Boehm and Knie, in animals when poisoned by small doses of prussic acid, and should always be assiduously practised. Next to it in importance is the use of the alternate cold and hot douche, about a half of a small bucketful of cold water and the same quantity of very hot (115° F.) water being dashed upon the chest in rapid succession.

ADMINISTRATION.—The dose of the dilute prussic acid (*Acidum Hydrocyanicum Dilutum*, U.S.) is one to three drops.

Potassium Cyanide (POTASSII CYANIDUM, U.S.) is prepared, according to the U.S. Pharmacopœia, by heating together the ferrocyanide of potassium and the carbonate of potassium. It occurs in white, amorphous, opaque masses, having the odor of prussic acid and a taste of similar character, but somewhat alkaline. It is deliquescent, and readily soluble in water. When the nitrate of silver is added to its solution, there falls a precipitate of the cyanide of silver, which is wholly soluble in ammonia.

When cyanide of potassium is taken into the stomach, the acids there present convert it into prussic acid, and the same change probably occurs, although more slowly, even when the salt is injected directly into the blood-vessels. The physiological, therapeutical, and toxicological properties of this salt are similar to those of prussic acid.* Death, however, does not occur so soon as when hydrocyanic acid has been taken, and insensibility is sometimes not manifested for several minutes. Five grains of the salt have caused death in several cases. The therapeutic dose is one-tenth to one-twelfth of a grain.

Silver Cyanide (ARGENTI CYANIDUM, U.S.) is a white insoluble powder, which is used solely for making prussic acid.

Cyanogen Gas has been studied physiologically by Dr. B. Bungo (*Arch. f. Exper. Path. u. Pharm.*, xii. 71). He finds that it kills by paralyzing the centres of respiration, but that it is less powerful and strong in its influence than is hydrocyanic acid, and causes only very feeble convulsions.

VEGETABLE ACIDS.

Although most of the officinal vegetable acids differ so much from the other substances considered in the present class as not to be poisonous except in enormous doses, and although they are never used to produce a profound impression upon the circulation, yet, since they have, or at least are believed to have, the power of lowering the force of the cardiac movements to some extent, and since they are so commonly believed to have a tendency to depress animal temperature as to

* Poisoning is stated to have occurred from the inhalation of the vapors of the cyanide; and, in photographers, from the absorption through the hands (*Brit. and For. Med.-Chir. Rev.*, July, 1876, p. 231).

be usually spoken of as *refrigerants*, the present seems to me a fitting place for their consideration. In experiments made by W. H. Gaskell (*Journ. of Physiol.*, iii. 49), similar to those described in the article on *digitalis* (see p. 353), it was found that while alkalis contracted the arterioles of the frog, acids* caused a dilatation, probably by paralyzing the muscular coats. Acids also diminished the activity and power of the frog's heart.

ACIDUM TARTARICUM—TARTARIC ACID. U.S.

Tartaric acid occurs in large, hard, transparent, six-sided prisms, which are pyro-electric and phosphorescent when rubbed in the dark, and are nearly free from odor, but have a very sour taste. In the shops the acid is almost always kept in the form of powder. Tartaric acid is the acid of the grape, and occurs in grape-juice as a supertartrate of potassium. When the juice undergoes fermentation and alcohol is developed, the acid salt, not being soluble in the newly-formed menstruum, precipitates, collecting as a dark mass in the wine-casks, whence it is sent into commerce under the name of *argol* or *tartar*. Out of this substance the acid is manufactured by treating with lime, so as to form a tartrate of calcium, and precipitating this new compound in its watery solution by sulphuric acid, sulphate of calcium falling, tartaric acid remaining in solution. Tartaric acid is soluble in little more than half its weight of hot water and in less than its weight of cold water. It is distinguished from all other acids by forming a crystalline precipitate (bitartrate) when added to a neutral solution of potassa.

Physiological Action.—When applied to a denuded surface, or in sufficient concentration to a mucous membrane, tartaric acid acts as a very decided irritant, and even upon the skin its saturated solution after a time causes redness and burning.

When the drug is taken internally in sufficiently large doses, it acts as an irritant poison, causing violent oesophageal and gastric burning, vomiting, and, it may be, fatal gastro-enteritis.† Upon animals it acts in large doses precisely as it does upon man. Thus, Mitscherlich states that three or four drachms suffice to kill a rabbit, the evident symptoms being great weakness of the heart's action, difficult and slow breathing, and steadily-increasing pains, with slight convulsions before death. According to Devergie, it requires nearly half an ounce to kill a dog when given by the stomach; but Pommer (quoted by Husemann) asserts that one gramme (15.34 grains) injected into the crural vein of a dog will produce death.

* Lactic acid appears to have been the only one used, and it does not appear certain that the results of experiments would be the same with all acids, as is stated in Gaskell's generalization.

† Case reported in the *Brit. Med. Journ.* for June, 1893, in which the supposed dose was one hundred and eighty grains. Symptoms: diarrhoea, violent abdominal pains becoming more and more marked, followed by fever, delirium, and death on the seventh day. At the autopsy violent inflammation of the whole of the gastro-intestinal tract was found.

Tartaric acid is never used internally by practitioners in such doses as to cause any of the symptoms above detailed, and it is evident that these symptoms throw little light upon its action in therapeutic doses, except to render it somewhat probable that the tendencies of the medicine are to lower cardiac action. This probability is increased very much by the experiments of Bobrick (quoted by Husemann, *Die Pflanzstoffe*, p. 561), who found that very large doses render the heart's action weaker and slower.

A great deal of interest to the therapist centres in the question as to what becomes of the acid in the system. Unfortunately, our knowledge in regard to this matter is far from complete; but the drug is probably partially burnt up in the body and partially eliminated by the kidneys. Wöhler,* in his experiments, found it in the urine in the form of tartrate of calcium, while Buchheim* and Piotrowski* could find only a very small percentage of the ingested acid in the urine, and conclude that it is mostly destroyed in the body. Dr. Münch (*Archiv des Vereins für Gemein. Arbeiten*, 1863, p. 370) finds that when tartaric acid or citric acid is given it soon appears in the urine. Dr. H. Bence Jones (*Medical Times and Gazette*, 1854, vol. ix. p. 408, and *Lectures on Pathology and Therapeutics*, London, 1867) has found that both citric acid and tartaric acid cause a pronounced increase in the acidity of the urine of persons taking them, and are apt also to give rise to the presence of free uric acid in the excretion. Unfortunately, Dr. Jones did not attempt to determine whether the increased acidity was or was not due to the presence of the vegetable acid in the urine.

THERAPEUTICS.—Tartaric acid is rarely used in medicine, citric acid almost always being preferred. It may, however, be employed whenever it is desired to render the urine acid, in doses of ten to twenty grains; but it is less valuable than the acid of the lemon.

TOXICOLOGY.—There are, I believe, but three fatal cases of tartaric acid poisoning on record: one reported by Devergie (*Ann. d'Hygiène*, 1851, t. ii.); one by Professor Taylor (*Principles and Practice of Medical Jurisprudence*, London, 1873, p. 230), in which death took place nine days after the ingestion of an ounce of the poison dissolved in half a pint of water; and one (*Med. Press and Circular*, Nov. 1880) in which a half-ounce of the acid was supposed to have been taken. The treatment of tartaric acid poisoning consists in the free exhibition of magnesia, of lime, of carbonate of potassium or of sodium, or of any article, such as soap, containing an alkali in a suitable shape, which may be at hand. The after-treatment is that of toxic gastro-enteritis.

ACIDUM CITRICUM—CITRIC ACID. U.S.

Citric acid is the acid of lemon- and lime-juice, from which it is extracted by a process precisely similar to that employed in the manufac-

* All these are quoted by Husemann, *Die Pflanzstoffe*. I have not seen the originals.

ture of tartaric acid. It occurs in rhomboidal prisms, which are sometimes very large, are nearly free from odor, but are possessed of a very sour, almost corrosive, taste, which, when the acid is in sufficiently weak solution, is quite pleasant. Citric acid is soluble in three-fourths of its weight of cold water, in half its weight of boiling water, in alcohol, and in eighteen parts of ether.

It is sometimes adulterated with tartaric acid, which may be readily detected by the addition of a strong neutral solution of carbonate of potassium to a strong solution of the suspected drug: if tartaric acid be present in any amount, a precipitate of the bitartrate will be formed.

PHYSIOLOGICAL ACTION.—Citric acid in concentrated solution certainly acts upon abraded surfaces and upon mucous membranes as an irritant, but, according to Mitscherlich, is less irritant than tartaric acid, since its concentrated solution has no action upon the sound skin.

No case of poisoning by citric acid has occurred in man, that I am aware of, and Piotrowski (quoted by Husemann, *Die Pflanzenstoffe*, p. 561) took, in six hours, thirty grammes, an hour later fifteen grammes, and an hour later thirty grammes, or nearly two ounces and a half in all, with the induction of no more serious symptom than vomiting. It is, therefore, somewhat doubtful whether citric acid is capable of causing death in man. This difference in action between it and tartaric acid may depend upon the latter being so much the more irritant of the two: upon the urinary secretion their action is probably similar.

Hugo Schulz states that citric acid is an active antiseptic, a five-per-cent. solution being sufficient to preserve small pieces of meat for two weeks; one part in a thousand was fatal to paramoecia (*Deutsch. Med. Wochenschr.*, 1883, ix. 398).

THERAPEUTICS.—Citric acid is sometimes itself employed in medicine, but is almost exclusively used in the form of *Lemon-juice* (*Succus Limonis*), which some, it is true, have thought to be dependent upon citrate of potassium for much of its virtue, but which contains, as shown by the analysis of Professor H. Bence Jones (*Medical Times and Gazette*, vol. ix., 1854), in every ounce twenty-six or twenty-seven grains of free citric acid, and not two grains of citrate of potassium.

Lemon-juice has several very distinct uses in medicine, all of them resting upon clinical rather than physiological data. The chief and most important of these is in the cure and prevention of *scurvy*. During the disease it should be drunk freely in the form of lemonade, three or four ounces of it being taken daily. As a prophylactic against the disease, lemon-juice is simply invaluable; but it is absolutely necessary that it be of good quality. It may be prepared for long voyages in one of two ways: first, boil the juice slightly, strain, allow to cool, pour into bottles up to their necks, fill the vacant space above with pure olive oil, cork tightly, and keep the bottle upright; second, add ten per cent. of brandy, and bottle as before (*Medical Times and Gazette*, 1854, p. 635). Citric acid is of some value in scurvy, but is incom-

parably inferior to lemon-juice. In *acute rheumatism*, benefit may be derived from the free use of lemon-juice, as originally proposed by Dr. Rees, of London. One or two ounces of it may be given four or five times a day; but it is certainly less efficacious than the alkalies. In *catarrhal jaundice*, and in *habitual torpor of the liver*, the free administration of lemon-juice often aids in effecting a cure. In *fevers*, lemonade may be a very refreshing and useful refrigerant drink.

ADMINISTRATION.—Lemon-juice, when it can be had, should always be preferred to citric acid; when only the latter is available, an artificial lemon-juice may be made by dissolving in a pint of water an ounce of the acid with which four drops of the oil of lemon have been well rubbed up.

ACETUM—VINEGAR.

The physical properties of vinegar are too well known to need description here. That best suited for medicinal use is in this country prepared from cider, and should have a trace of the taste of cider. It is sometimes adulterated with sulphuric acid, which may be at once detected by boiling with chloride of calcium, which precipitates any free sulphuric acid as sulphate of calcium, without affecting the small proportion of soluble sulphates existing in vinegar. Vinegar may be substituted for lemon-juice as the basis of an acidulous drink in fever when the lemon-juice is not to be had; but as an *antiscorbutic* it is certainly very much inferior to it, and has not, that I am aware of, been tried in *rheumatism*.

Acetic Acid (ACIDUM ACETICUM, U.S.) is a colorless liquid, having a pungent odor, free from empyreuma, and an intensely acid, corrosive taste. It contains thirty-six per cent. of the monohydrated acetic acid, and has a specific gravity of 1.047. Glacial or monohydrated acetic acid is not officinal. It is a colorless liquid, crystallizing at 34° F., and actively escharotic,—in a measure, no doubt, owing to its properties of dissolving gelatin and gelatinous tissue and of effecting a partial solution of albuminous matters. *Dilute Acetic Acid* (ACIDUM ACETICUM DILUTUM) is officinally prepared by the addition of five parts of water to one part of acetic acid, and should have the sp. gr. 1.008. *Acidum Aceticum Glaciale*, U.S., *glacial* or *absolute acetic acid*, is at 59° F. a crystalline solid.

Dilute acetic acid, or its equivalent, vinegar, is a useful topical application in various superficial inflammations of the skin, such as "sunburn," and in *sprains*. Applied to the skin, it acts as a powerful stimulant and astringent, causing contraction of the vessels and great whiteness. Diluted with two or three times its bulk of water it is occasionally employed as an injection against *seat-worms*; but the infusion of quassia is preferable.

The use of acetic acid as a caustic will be spoken of under the heading of *Escharotica*.

TOXICOLOGY.—Acetic acid in any of its more concentrated forms is

a corrosive poison, and death has been produced by it in at least one case (Orfila, *Toxicologie*, t. ii.). The symptoms resemble those caused by mineral acids, and the treatment is exactly similar,—neutralization by an alkali or its carbonate, or by some substance, such as soap, containing an alkali, and the meeting of indications as they arise.

Oxalic Acid (ACIDUM OXALICUM) has been asserted (*Gaz. Hebdom.*, xxiii. 128) to be a valuable emmenagogue, but it is chiefly known to the profession as a poison. In 1874 (*Gaz. Méd.*, p. 92) Rabuteau announced that in oxalic acid poisoning the nerves and muscles are not affected, and that therefore the acid acts upon the nerve-centres. This has been confirmed by the elaborate researches of Drs. R. Kobert and B. Küssner (*Virchow's Archiv*, lxxviii. 109), who find that it paralyzes the respiratory, vaso-motor, and other motor spinal centres. It is also a cardiac poison, arresting the heart in systole (*Les Nouveaux Remèdes*, 1886, ii. 290). The acid is eliminated by the kidneys. As a poison, oxalic acid figures in two forms: that of simple oxalic acid, and that of the acid oxalate of potassium, or salt of sorrel, or essential salt of lemons, as it is variously termed in common parlance. The symptoms produced are a hot acrid taste experienced during the swallowing, a burning in the gullet, soon extending to the stomach, intense abdominal pain, vomiting of highly acid, greenish, blackish-brown or bloody mucus (rarely of arterial blood), collapse, livid surface, cold skin, entire prostration of strength, small irregular pulse, stupor, unconsciousness, sometimes convulsions (cases, *Guy's Hosp. Reports*, 1838, iii.; *Dublin Hosp. Reports*, 1818, ii.); and finally death. In some cases the gastric symptoms are very prominent; in others they are nearly wanting, and the chief manifestations are collapse and such nervous symptoms as almost complete general paralysis, numbness, and finally stupor; indeed, the patient may suddenly fall unconscious immediately after the ingestion of the poison (case, *Guy's Hosp. Reports*, 1874). According to Taylor, the smallest quantity which is known to have caused death is one drachm. An ounce usually proves fatal, but has been recovered from. After death the coats of the stomach are usually found softened and swollen, and sometimes perforated (case, *Edinb. Med. Journ.*, vii., July, 1861). Dr. Rabuteau (*Gaz. Méd.*, 1874, p. 93) affirms that the blood is everywhere scarlet; but this is certainly not always the case (case, Taylor, *Medical Jurisprudence*, i. 224). In 1879, Kobert and Küssner discovered that oxalic acid will produce in the lower animals not only oxaluria and albuminuria with tube-casts, but also glycosuria.* In 1883, Sarganeck discovered sugar in the urine in human poisoning, and the recent investigations of Kobert have shown that in rabbits and cats even non-poisonous doses of the acid cause the appearance of a fermentable sugar in the urine. It would seem, therefore, that gly-

* Kobert has made the very important observation, that the extract of *Syzygium jambolanum* will control the glycosuria produced by oxalic acid.

cosuria should hold an important place among the diagnostic symptoms of the poisoning. According to Kobert and Küssner, a pathognomonic post-mortem lesion is the incrustation of the urinary tubules with crystals of oxalates. In poisoning by oxalic acid, the immediate administration of an antidote is of the utmost importance. As the potassium and sodium oxalates are poisonous, neither potash nor soda is available; but, fortunately, lime or chalk is a perfect antidote to oxalic acid, forming the excessively insoluble calcium oxalate. As time is a matter of so much importance, very often it is best simply to scrape "white-wash" off a wall, a ceiling, a fence, or wherever it may be at hand, rub it up hastily with water, and administer it freely. The after-treatment is that of toxic gastro-enteritis.

As an emmenagogue, oxalic acid has been used in all forms of *amenorrhæa* with assorted great success. It is said also to be an active abortifacient. The dose usually given is half a grain three or four times a day; but Dr. F. W. Talley has reported serious poisoning as produced by this amount.

Oxalic acid is a powerful germicide. According to O. Loew, the one-per-cent. solution of the neutral potassium oxalate is very active in the destruction of infusoria (*Sitzun. d. Gesell. f. Morphol. und Physiol.*, viii., 1892), whilst Professor Howard A. Kelly claims that potassium permanganate and oxalic acid afford the only known practical method of perfectly disinfecting the hands of the surgeon (*Amer. Journ. of Obstetrics*, xxiv., 1891).*

* The exact method practised by Professor Kelly is as follows: 1. Scrubbing the hands, with especial attention to the nails,—not more than one millimetre in length,—for ten minutes in water frequently changed, at about 40° C. (104° F.). 2. Immersion of the hands in a solution of potassium permanganate, made by adding an excess of the salt to boiling distilled water, until every part of the hands and lower forearms is stained a deep mahogany red, or almost black color, followed by transfer to a saturated solution of oxalic acid until completely decolorized and of a healthy pink color. This decolorization is accompanied by a sense of warmth, due to chemical reaction, and a sharp stinging wherever there is any abrasion of the epidermis. 3. Washing off the oxalic acid in warm sterilized water.

ORDER III.—NUTRIANTS.

FAMILY I—ASTRINGENTS.

ASTRINGENTS are those drugs which cause contraction of living tissues. That they do not act, as has been supposed, either by coagulating albumen or by calling into action the muscular function, is demonstrated by the transitoriness of their effects, and by the fact that they influence tissues containing no muscular fibre. Every living soft tissue appears to possess a normal degree of condensation, which may be departed from on either hand: when this happens, in the one case the part is said to be relaxed, in the other to have its tonicity increased, or to be astringed. The action of astringents is always a *local one*,—i.e., produced not through the intervention of the nervous system, but by direct contact with the part affected. A pure astringent should be capable of doing nothing beyond inducing contraction; but in reality there is scarcely such a drug. All known astringents are, when applied too freely, irritants.

The action of astringents upon blood-vessels has been experimentally investigated by M. Rosenstein (*Rosbach's Pharmakolog. Untersuchungen*, Bd. ii.), and more recently by Dr. R. Heinz (*Virchow Archiv*, Bd. cxvi., 1889). The results show that medium solutions of tannic acid, alum, and the salts of lead, zinc, iron, copper, and mercury, contract the vessels by a direct action. When, however, the solutions are too strong, according to Heinz, this contraction is followed by dilatation. Both experimenters state that the nitrate of silver is the most powerful in its influence, producing an almost permanent contraction. According to Rosenstein, acids cause dilatation of the capillaries.

The clinical results obtained by the use of astringents in the treatment of inflammation can hardly be due to their action upon the blood-vessels, but seem to find more appropriate explanation in the discovery of Heinz, that, locally applied, they decidedly check the outwandering of the white blood corpuscles, probably, as he thinks, by modifying the wall of the blood-vessel.

The chief indication for the use of an astringent is the *existence of relaxation*. Local relaxation is commonly due to previous over-excitement. Thus, a throat is relaxed after over-use, or after inflammation.

Astringents are more efficient as local than as general remedies, but in cases of inflammation care must be taken to use them in such a way that they shall not act as irritants. Applied too soon or too vigorously,

they may do harm. These remarks are scarcely applicable to some of the mineral astringents, such as lead and nitrate of silver, which really appear to have sedative properties, and may with care be used advantageously in all stages of inflammation, whenever there is distention and relaxation of the blood-vessels, although the general action of the part be that of nutritive excitement.

Closely allied to relaxation is *over-secretion*, and astringents are constantly used to *check morbid discharges*. Indeed, these discharges are often simply the result of relaxation. Thus, Asp has experimentally proved that division of the intestinal nerves and consequent paralysis and relaxation of the vessels are followed by free watery secretion. In such cases the indication for astringents is very plain. But when a morbid discharge represents a high degree of inflammation, the same care must be practised in the use of astringents as in treating other local inflammations. Especially is this true since free secretion is often nature's method of relieving local inflammation. Thus, when abnormal alvine discharges are dependent upon intestinal relaxation, astringents are most valuable, but when they are dependent upon enteritis or colitis, astringents may do harm.

If the morbid discharge by its profuseness endangers life, as in serous diarrhoea, astringents are urgently demanded. Very rarely, if ever, are these discharges other than paralytic in their origin; even, however, if they be due to over-action, an astringent may be necessary to check their excessiveness.

Another indication for the use of astringents is to *check hemorrhage*, and the same general reasoning is applicable to this as to the other indications. Hemorrhage dependent upon over-action demands other treatment than by astringents. Sometimes in these cases it is necessary, however, to check the hemorrhage at all hazards, and then astringents may be used in conjunction with other measures, although they may be to some extent contra-indicated. Some of the astringents are employed locally to check hemorrhage due to traumatic or other ruptures of vessels. In such cases the astringents are employed as *styptics*, and do not act so much by their astringency as by coagulating the albumen of the blood and thus forming a clot and mechanically arresting the flow.

Under certain circumstances there seems to be a general relaxation or loss of tone throughout the whole system, which may be best met by a consensual use of tonics and astringents.

VEGETABLE ASTRINGENTS.

The active principle of the vegetable astringents is tannic acid, and, as it is almost their sole therapeutic principle and represents them very closely, it seems proper first to consider it, and afterwards to point out any especial therapeutic virtues the crude drugs of the class may possess.

ACIDUM TANNICUM—TANNIC ACID. U.S.

There are two kinds of tannic acid, the *gallo-* and the *kino-tannic*: of these the former yields, upon exposure to the air in a moist state, *gallic acid*, the latter a *gelatinous, inert* substance. They are further distinguished by the color of the precipitates which they yield with the persalts of iron; gallo-tannic acid producing a blue-black, kino-tannic a green-black color.

The officinal tannic acid—the gallo-tannic acid—is obtained by treating powdered galls with washed ether, which on standing separates into two strata, the upper of which is ethereal and contains chiefly the coloring-matter and other impurities. The lower watery stratum contains the tannic acid, which is recovered by evaporation.

Commercial tannic acid is a light, feathery, *non-crystalline* powder, of a yellowish-white color, a faint odor, and an astringent, somewhat bitter taste. When absolutely pure, it is colorless and free from odor or taste other than that of astringency. Its reaction is strongly acid, and it unites freely with both organic and inorganic bases. It is very freely soluble in water, even more so in glycerin, somewhat so in dilute alcohol, scarcely at all in absolute alcohol, and not at all in ether free from water. By a heat of from 108° C. to 215° C. it is changed into *pyrogallie acid*, which crystallizes in white, shining plates, of a bitter taste and neutral reaction. With salts of the alkaloids it produces a whitish precipitate, very soluble in acetic acid; with persalts of iron, a black (bluish or greenish) precipitate; with lime-water, a precipitate which is at first whitish, then gray, dingy greenish, and finally brownish; with gelatin or albumen, a whitish coagulum. All of these secondary products are tannates. Tannic acid also dissolves in concentrated sulphuric acid, with the production of a black color. By prolonged exposure in solution to the air, or by the action of dilute sulphuric acid, it is converted into gallic acid.

PHYSIOLOGICAL ACTION.—When applied locally to a part, tannic acid is a very powerful astringent, causing contraction, and, in the case of a mucous membrane, great dryness. Sometimes, when it is used very freely, its irritant influence seems to overcome its astringent action, and I have seen diarrhoea result from its administration. Several experimenters (Rosenstein, *Untersuch. Pharmakolog. Institut Würzburg*, 1875; Fikentscher, *Inaug. Dissert.*, Erlangen, 1877) have denied that it causes contraction of the blood-vessels, because when they applied it to the exposed mesentery of a "Cohnheim frog," stasis of the blood, with dilatation of the vessels, not preceded by contraction, occurred. Daniels, however (*Inaug. Dissert.*, Bonn, 1864), using rabbits, obtained different results, and Lewin has shown that the method of experimentation is faulty. Clinical experience abundantly proves that tannic acid applied to relaxed mucous membranes affects their whole substance.

Tannic acid coagulates albumen with so much avidity that it has been

supposed to be incapable of absorption, but the very elaborate investigations of Dr. Lewin cast much doubt upon the older views on this subject (*Virchow's Archiv*, lxxxi. 74). Thrown rapidly into the blood, it undoubtedly causes a fatal thrombosis; but Lewin asserts that when it is injected slowly and in moderate quantities the resulting tannate of albumen is held in solution by the alkaline carbonates of the blood. He has also discovered that while tannin, in five-per-cent. solution, precipitates peptones out of watery solution, it is powerless in the presence of hydrochloric acid. Assuming the correctness of the investigation of Dr. Lewin, it is plain that tannic acid, when put in the stomach in small doses, must to some extent be absorbed unchanged. Dr. Lewin also asserts that it is, at least in part, eliminated unaltered, as he has frequently recovered it from the urine. At the same time it seems very probable that most of the tannic acid is converted into gallic acid, either in the stomach before absorption, or subsequently in the system, since in the viscera of a rabbit poisoned with it, Schrott (*Die Pflanzenstoffe*, Husemann, p. 1005) found only gallic acid; and according to Clarus (*Ibid.*) the greater part of ingested tannic acid can be recovered from the stools as tannate of albumen or as gallic acid. The recent researches of Stockman (*Brit. Med. Journ.*, Dec. 4, 1887) afford a possible reconciliation of the results of Lewin with those of the older observers. Stockman finds that when tannic acid is given to the lower animals only a trace of it appears in the blood, while gallic acid can be obtained in abundance from the urine, with occasionally a small amount of tannic acid. If, however, tannate of sodium be given, tannic acid appears in abundance in the urine, with a little gallic acid. The explanation offered by Stockman of this is probably correct,—namely, that tannic acid is usually converted in the stomach into a tannate of albumen, which is dissolved with great difficulty in the intestinal juices, so that time is afforded for the conversion of the tannic into gallic acid, whereas an alkaline tannate is absorbed at once and rapidly eliminated unchanged. When tannic acid is exhibited in medicine it is in all probability almost entirely converted into gallic acid. Wöhler and Frerichs have also found gallic acid with pyro-gallic acid in the urine after the exhibition of tannic acid. Whether it acts chiefly as tannic or as gallic acid, it seems after absorption to exert marked astringent powers. Lewin has shown that in frogs poisoned with it the muscles are shortened and narrowed, and when loaded stretch less and recover their original length more nearly than do normal muscles. Küchenmeister (*Arch. Physiolog. Heilk.*, 1851, 493) and Hennig (*Arch. Pharmak.*, Feb. 1853) state that in poisoned cats the spleen is notably diminished in size and increased in firmness; and Lewin has found in rabbits that tannic acid causes primary arrest of the urinary secretion, followed by a marked increase of the flow.

THERAPEUTICS.—As tannic acid undergoes in the system partial conversion into gallic acid, the latter is to be preferred to it when the part

to be acted on can be reached only through the circulation. As a local application, tannic acid is much more powerful than gallic acid. Locally applied, it may be used to overcome relaxation, as in *spongy gums*, *mercurial sore mouth*, *hemorrhoids*, *chronic sore throat*. To check *hemorrhage* it may be used whenever the source of the flow can be reached directly, as in *epistaxis*, *hæmatemesis*, *hemorrhage from the bowels*, etc. To arrest *excessive secretion* it may be employed locally in *leucorrhœa*, *diarrhœa*, *old abscesses*, *chronic ulcers*, *excessive perspiration*, *osmidrosis*, and various diseases of the skin. It is also often very useful for the purpose of hardening parts exposed to friction, as in cases of *sore nipples* and *tender feet*.

TOXICOLOGY.—Tannic acid can scarcely be called poisonous; although Rollett reports the case of a young girl in whom a very large quantity of it induced severe gastric and abdominal pains, with obstinate vomiting and constipation, fever and general malaise. Both Schroff and Judell assert that eighty grains of it cause no symptoms of importance in the rabbit.

As an *antidote* it is useful in tartar emetic poisoning, forming an insoluble tannate of antimony. It is also the best chemical antidote for the poisonous alkaloids; but, as the compounds it makes with them are slowly dissolved by the fluids of the alimentary canal, it must always be followed by emetics and cathartics.

ADMINISTRATION.—When given to act on the stomach, as in hæmatemesis, tannic acid should be in powder (ten to twenty grains). When the bowel is to be influenced, as in diarrhœa, the drug should be administered in pill (three to five grains), so that, if possible, it may pass the pylorus undissolved. For local use the *glycerite of tannic acid* (*Glyceritum Acidi Tannici*, U.S., 20 per cent.) may be employed, or the *ointment* (*Unguentum Acidi Tannici*, U.S., 20 per cent.), or the *troches* (*Trochisci Acidi Tannici*, U.S., 1 grain each). Tannic acid enters into *styptic collodion* (*Collodium Stypticum*, U.S., 20 per cent.).

ACIDUM GALLICUM—GALLIC ACID. U.S.

Gallic acid is a white, powdery substance, in fine acicular prisms, soluble in one hundred parts of cold water, in three parts of boiling water, and freely soluble in alcohol and in ether. Its taste is acidulous and astringent.

According to the official method, gallic acid is prepared by the exposure of moistened powdered nutgalls in a warm place for a month. A species of fermentation, with the development of a peculiar fungus, is said to occur, during which oxygen is absorbed, carbonic acid is evolved, and glucose and gallic acid are produced. M. Sacc (*Chem. News*, July 24, 1871) has, however, denied this, affirming that the change is simply one of hydration, tannic acid being an anhydride of gallic acid. Tannic acid also may be rapidly converted into gallic acid by the action of dilute sulphuric acid.

Gallie acid produces with salts of the alkaloids whitish precipitates, with persalts of iron a bluish precipitate, with lime-water a whitish precipitate, changing to blue, and then to violet or purplish,—all of these precipitates being gallates. It does not coagulate gelatin or albumen, and dissolves in concentrated sulphuric acid, with production of a deep-red color. It has the power of reducing silver from its solution slowly in the cold, instantaneously if warmed. As an astringent it is similar to, but much less powerful than, tannic acid. It escapes from the body through the kidneys.

THERAPEUTIC ACTION.—Gallie acid is not nearly so efficient as tannic acid when applied locally, but, because it does not coagulate albumen, should always be preferred when the part is to be reached through the medium of the circulation. It is useful as an astringent in hæmoptysis, hæmaturia, colligative sweats, etc. It has been recommended in bronchorrhœa and in the profuse expectoration of chronic phthisis. In my hands, however, it has completely failed in the latter affections. In certain forms of *Bright's disease*, when there was no abnormally large secretion of highly albuminous urine, I have found it to lessen very materially the excretion of albumen.

ADMINISTRATION.—Gallie acid may be given in powder, or sometimes in pill form. The dose of it is from ten to thirty grains, repeated as often as may be necessary.

GALLA—GALLS. U.S.

Galls are vegetable excrescences which are produced by the deposition of the ova of insects. They occur on almost all kinds of plants, even on fungi, but the official gall is developed on the *Quercus lusitanica* by the act of the fly *Cynips gallæ tinctoriæ*. There are in commerce two varieties of galls, derived chiefly from the Levant. The *blue* or *green galls* are globular, solid bodies, from the size of a pea to that of a hickory-nut, externally smooth, or more commonly marked with large tubercles. They are the young galls which have been gathered before the ova of the fly have hatched, or before the caterpillar has eaten out the interior of its birthplace. The *white galls* are large, light, hollow bodies, with a hole, through which the *Cynips* has escaped after having fed upon the interior during its whole larval life. They contain but little tannic acid, and are of comparatively little value.

THERAPEUTICS.—The sole value of galls is as the source of tannic acid. As galls, they should not be used in medicine: but the United States Pharmacopœia recognizes a *tincture* (*Tinctura Gallæ*, 20 per cent.) and an *ointment* (*Unguentum Gallæ*, 20 per cent.).

CATECHU—CATECHU. U.S.

An extract of the wood of an East Indian tree,—the *Acacia Catechu*. It occurs in masses of various shapes, or in small fragments, of

a dull reddish-brown color, and having a bitterish, astringent, and, after a time, sweetish taste. It contains kino-tannic and catechuic acids. *Pale catechu*, or *gambir*, which is officinal in the British but not in the United States Pharmacopœia, occurs in small cubes, about an inch in diameter, lighter than water, pale-yellowish within, deep-yellowish or reddish-brown externally. Catechu is a powerful astringent, which may be used externally, or for *diarrhœa*, in the dose of twenty to thirty grains.

The U.S. Pharmacopœia recognizes a *compound tincture* (*Tinctura Catechu Composita*, 20 per cent.), of which the dose is one to three fluidrachms, and *troches* (*Trochisci Catechu*, 1 grain each).

KINO—KINO. U.S.

The inspissated juice of *Pterocarpus marsupium* and of other plants. It occurs in small, irregular, angular, shining, reddish, brittle fragments, of a bitterish, highly astringent, and, after a time, sweetish taste. There are four varieties,—the East India, West India, Botany Bay, and African. Of these, the first is common, the second rare, and the last two are never seen in our market. Kino contains kino-tannic acid, and in its therapeutic powers is almost identical with catechu. The dose is twenty to thirty grains. A *tincture* (*Tinctura Kino*, 10 per cent.) is officinal. Dose, one fluidrachm.

HÆMATOXYLON—HÆMATOXYLON. U.S.

The heart-wood of *Hæmatoxylon Campechianum*, or logwood-tree, a native of Central America,—a dense, heavy wood, of a deep reddish-brown color, containing, besides kino-tannic acid, a crystalline principle, *Hæmatin* or *Hæmatoxylin*, which when pure is yellow, but readily yields red or purple dyes. Hæmatoxylon is a mild efficient astringent, valued on account of its sweetish taste. It is readily taken by children, but is sometimes objected to on account of the staining of the diapers by the blood-red stools which it produces. The following formula offers an efficient and elegant remedy for *diarrhœas* of relaxation; the proportions may be varied to suit individual cases: R Ext. hæmatoxyli, ℥ii; Acid. sulph. aromat., f℥iii; Tinct. opii camph., f℥iiss; Syrupi zingiberis, q. s. ad f℥vi. M.—Dose, a tablespoonful, properly diluted. The *extract* (*Extractum Hæmatoxyli*) is officinal; dose, ten to thirty grains.

KRAMERIA—RHATANY. U.S.

The root of *Krameria triandra*, a native shrub of Peru, and of *Krameria ixina*, a shrub growing in Colombia, British Guiana, and Northern Brazil. This woody root, as it occurs in our markets, varies from one-fourth inch to one inch in diameter, and from half a foot to three feet in length. The readily separable bark is of a deep-reddish color. The internal woody portion is of a lighter hue, although decidedly reddish. The bark contains a much larger percentage of the

active principle, kino-tannic acid, than the wood. Rhatany is a powerful astringent, similar in virtue to kino and catechu, but is never administered in powder. The U. S. Pharmacopœia recognizes an *extract* (*Extractum Kramerie*), dose, grs. v-x; a *tincture* (*Tinctura Kramerie*, 20 per cent.), dose, half to one fluidrachm; and a *fluid extract* (*Extractum Kramerie Fluidum*), dose, twenty drops.

QUERCUS ALBA, U.S., and QUERCUS TINCTORIA are the inner barks of the trees whose names they bear,—the *white* and the *black oak* respectively. The latter is a rough, yellowish-brown bark, which is used in dyeing, under the name of *quercitron*. On account of its imparting readily its color, it is rarely, if ever, employed in medicine. White-oak bark also stains, but not nearly so deeply as does black-oak bark, and, containing largely of gallo-tannic acid, is used as a means of making cheap astringent infusions for baths, vaginal washes, etc., also in powder for poultices.

ROSA GALLICA, U.S., is the dried petals of the half-opened flowers of the hundred-leaved rose. They are of a deep-red color, of a pleasant scarcely astringent taste, and contain a small percentage of gallo-tannic acid, red coloring-matter, and a trace of volatile oil. Sulphuric acid changes their infusions or tinctures to a bright-red color. They are almost destitute of therapeutic virtues, but their preparations, except the fluid extract, are used as elegant vehicles. The U.S. Pharmacopœia recognizes a *fluid extract* (*Extractum Rosæ Fluidum*), a *honey* (*Mel Rosæ*, 12 per cent.), a *confection* (*Confectio Rosæ*), and a *syrup* (*Syrupus Rosæ*, fluid extract, 12.5 per cent.).

ROSA CENTIFOLIA, U.S., or *Pale Rose*, contains no tannic acid, but a volatile oil, and is used simply on account of its pleasant odor: out of it are prepared *rose water* (*Aqua Rosæ*, U.S.) and the very elegant, bland emollient ointment, *cold cream* (*Unguentum Aquæ Rosæ*, U.S.).

The rhizome of *Geranium maculatum* Linn., an herbal plant, which grows abundantly in open woods in the middle United States, and may be recognized by its light-purplish petals, slender pointed sepals, and five-parted leaves, is official under the name of GERANIUM. It occurs in pieces from one to three inches long, one-quarter to one-half inch in thickness, wrinkled, contorted, tuberculated, often fibrillated, brownish externally, grayish internally. The taste is a nearly pure astringent one. It contains largely of gallic and tannic acids, and is a somewhat popular astringent. It may be boiled in milk for children needing a mild astringent. Dose, grs. xx-xxx. The U.S. Pharmacopœia recognizes a *fluid extract* (*Extractum Geranii Fluidum*), the dose of which is thirty minims to a fluidrachm.

RHUS GLABRA. U.S.—The fruit or berries of the sumach contain a very large percentage of tannic and malic acids. They are not used internally, but their fluid extract (*Extractum Rhois Glabræ Fluidum*, U.S.) affords a very superior gargle in *anginose affections*. It may be diluted with from two to four parts of water, and chlorate of potassium added to saturation.

AGARIC.—Under the name of Agaric various species of fungi belonging to the genus *Boletus* have been employed from time to time in medicine. Of these the *white agaric*, or *purging agaric* of writers is obtained from *Boletus lareis*, the fungus of the European larch. It contains a whitish, very bitter acid, variously known as *agaric acid*, or *agaricinic acid*, slightly soluble in cold water, moderately so in hot water. According to the researches of Hofmeister (*Archiv Exper. Path.* 1889), agaric acid has upon the lower animals very little influence except in arresting the secretion of sweat by paralyzing the peripheral nerves of the sweat-glands. Both the impure extract, known in commerce as *agaricin*, and agaric acid have been extensively used for the purpose of arresting *colligative sweats*, and in my own experience are valuable remedies. The only untoward effect ever produced, even by the largest dose, is irritation of the gastro-intestinal canal. Two to five grains of the agaricin may be given three times a day, commencing with the smaller dose and increasing. According to Hofmeister, the dose of the pure acid is from one-sixteenth to one-third of a grain.

MINERAL ASTRINGENTS.

ALUMEN—ALUM. U.S.

Formerly the double salt of alumina and potash constituted the ordinary alum as well as the officinal drug. Ammonia as a secondary product in the manufacture of coal-gas has become so cheap, however, that it is now used very largely instead of potash, although the potash alum is alone recognized in our officinal standard. The two salts are identical in physical and medical qualities, but when the ammonia alum is triturated with lime the odor of ammonia is at once evolved. Alum occurs in octahedral colorless crystals, which are often aggregated into large masses. Its taste is astringent, acidulous, and sweetish. It is soluble in nine parts of water at 59° F. and in one-third part of boiling water. It is slightly efflorescent, and when heated parts with its water of crystallization and is converted into a white powder, which is officinal as *Alumen Esuscatum*, or *Dried Alum*. The alkalis and their carbonates, lime, magnesia and its carbonate, potassium tartrate, and lead acetate are incompatible with alum.

PHYSIOLOGICAL ACTION.—As alum, even in very dilute solutions, coagulates albumen, it would appear as though it could not be absorbed. Since, however, both Drs. Geo. B. Wood and A. Stillé assert, on what

authority I do not know, that alumina can be detected in the urine of persons taking it, it or its derivatives must find a way into the blood. What changes it undergoes in the alimentary canal, or in what form it enters the blood, is not known.

Applied to a tissue, it acts as a very powerful astringent and irritant. Orfila found that in dogs one or two ounces of it simply induce violent vomiting and purging, while in Mitscherlich's experiments two drachms of it produced in rabbits fatal gastritis, evidently on account of their inability to vomit.

In man, large doses internally produce symptoms of violent gastric irritation. One ounce and five drachms of the burnt alum caused death in a man in eight hours (*L'Union Médicale*, No. 64, 1873).

THERAPEUTICS.—Alum may be used locally to serve all the purposes of a very active astringent. It has been employed very frequently with success as a styptic to arrest hemorrhage; and, applied by the atomization of its saturated solution, I have found it of signal service in *hæmoptysis* and in *branchorrhæa*. It also frequently enters into the composition of gargles for *sore throat*; but this practice is to be reprobated, since alum acts very destructively on the teeth. In *colliquative sweats*, sponging at bedtime with alum-water, or, still better, the taking of an alum-water bath, will often materially aid in restoring the lost tone to the skin. In *chronic ulcers* with exuberant spongy granulations, and in certain conditions of *conjunctivitis*, alum curd is often applied with benefit. When it is desired to exert an astringent action upon the internal organs, alum is not nearly so useful as other members of the class.

Owing to its irritant properties, alum when given in sufficient amount acts as a mechanical emetic, and may be used as an adjuvant to the sulphate of zinc or of copper in narcotic poisoning. Originally introduced by Dr. C. D. Meigs, it is believed to be of service in *membranous croup* not only by its emetic action, but also by modifying the mucous membranes with which it comes in contact in its passage down and up.

So long ago as the last century, Dr. Grashius, of Holland, commended alum in *colica pictonum*, and, although for a long time its value was not recognized, abundant confirmative testimony has recently been brought forward. Since it is a soluble sulphate, it is of course a chemical antidote to any lead salt which may be in the alimentary canal. It is, however, of service when there is no lead in the *primæ viæ*, and must act in some way as yet unknown. It has, indeed, been used with asserted success in other neuroses of the alimentary canal,—in *gastralgia* and in *intestinal neuralgia*. Dr. Aldredge even commends it in *habitual constipation*. *Burnt alum*—i.e., alum which has had its water of crystallization driven off by heat—is used as a very mild escharotic for the destruction of exuberant granulations in ulcers.

ADMINISTRATION.—As an astringent, the dose of alum is from ten to twenty grains; as an emetic, a teaspoonful of the powder for a child,

a tablespoonful for an adult, in syrup, repeated in fifteen minutes, in *colica pictorum*, twenty to forty grains every three or four hours, combined with morphine. *Alum curd* may be made by dissolving two drachms in a pint of milk, and straining, or by rubbing the alum with white of egg.

ALUMINI SULPHAS—ALUMINUM SULPHATE ($\text{Al}_2\text{O}_3\cdot 3\text{SO}_4 + 18\text{HO}$ — $3\text{SO}_4\cdot \text{Al}_2 + 18\text{HO}$), U.S.—This salt, which occurs as a white powder, or in lamellated cakes, or in a crystalline cake, is used externally as a powerful astringent and antiseptic. Its solution has also been employed by injection for the preservation of cadavers.

PLUMBUM—LEAD. (Pb.)

When a soluble salt of lead is applied to a part in not too concentrated solution, it acts as an astringent and sedative. Owing to the contraction of the vessels which is induced, the tissue becomes blanched, and any inflammatory action which may be present is remarkably affected. When in concentrated solution, the mildest preparations of lead are capable of acting as irritants, increasing or even originating inflammation. When the salts of lead are taken internally in therapeutic doses, no decided symptoms are generally induced, except a diminution of the secretions, especially of those of the alimentary canal. Sometimes, when full therapeutic doses are exhibited, a slight lowering of the frequency and force of the pulse (see Laidlaw's *Observations*, quoted by Stillé, *Therapeutics*, second edition, vol. i. p. 177) is said to result, but I have never witnessed this. The insoluble preparations of lead act similarly to but less decidedly than the soluble; yet it is doubtful whether they can under any circumstances become irritant.

Toxicology.—Acute lead-poisoning is usually produced by a soluble salt, notably the acetate;* but a case reported by Dr. Freyer (*Zeitschr. f. Med. Beamte*, i., 1888) shows that white lead and other insoluble preparations may act as violent and even fatal irritant poisons. When the acetate is ingested in toxic dose, the first symptom is usually a persistent sweet, somewhat metallic taste; this in a few minutes is followed by vomiting, which may or may not be preceded by nausea. The matters vomited are often milky-white, from the presence of chloride of lead. A severe burning persistent pain in the abdomen now comes on, and is accompanied with a craving for drink. There may be obstinate constipation, or diarrhœa may ensue: in either case the stools are generally black from the sulphuret of lead. In certain cases a state of collapse is developed; the pulse falls to forty or fifty per minute, the voice is lost, the face is deadly pale, the lips are livid, and syncope seems imminent. In other instances the nervous symptoms may predominate, or they may accompany those of disordered circulation: cramps in the calves of the legs, severe neuralgic pains in

* According to Husemann (*Handbuch der Toxicologie*), the *poudre de succession*, so famous during the reign of Louis XIV., was composed chiefly of acetate of lead.

the extremities, paralysis and anæsthesia, vertigo, stupor, may any or all of them be present. In fatal cases, coma, with or without convulsions, finally develops. A distinctive mark of lead-poisoning, which occasionally is present very early, is the blue line upon the gums. After death inflammation of the alimentary mucous membrane is sometimes, but not always, found. One ounce of the acetate, subacetate, or nitrate of lead may take life.

The treatment of *acute lead-poisoning* consists in the evacuation of the stomach, the exhibition of the sulphate of sodium or of magnesium, and the meeting of the indications as they arise. The Epsom and Glauber's salts act as chemical antidotes, by precipitating the insoluble sulphate of lead, and also, if in excess, empty the bowel of the compound formed. To allay the gastro-intestinal irritation, albuminous drinks should be given and opium freely exhibited.

Subacute and chronic lead-poisoning are almost always accidental, and occur most frequently among those whose occupation exposes them to daily contact with some compound of the metal; manufacturers of white lead, painters, glaziers, and similar artisans furnish the greater number of victims. They may be seen, however, in persons of all conditions of life, for although neither food nor drink is often purposely adulterated with lead, yet it is frequently introduced into the system accidentally along with those necessities. Lead pipes are habitually used for the conveyance of water, and when the water contains salts of lime, even in minute proportion, no evil results, because through the decomposition which ensues insoluble coatings are deposited on the inside of the pipes.* When the water is pure, no such reactions occurring, the lead is slowly dissolved in the form of a carbonate, and poisoning may result. Poisoning has also frequently resulted from the use of cosmetics and hair-dyes, from cooking bread with painted wood (*Le Progrès Méd.*, 1877, 349), from imperfectly-burnt pottery (*Schmidt's Jahrb.*, Bd. cxliv. p. 279; *Phil. Med. Times*, vol. iv. pp. 241, 483), from habitually biting silk thread which rascally manufacturers often load with lead to give weight to it,† and in other curious ways.

That form of lead-poisoning in which colic is the most decided symptom is often spoken of as *subacute*. After some days of malaise and wretchedness, or sometimes very suddenly, the victim is taken with abdominal colicky pains, which increase in intensity until they become very severe. They are constant, with occasional exacerbations, are sometimes dull, sometimes sharp, are generally described as twisting, and seem to centre around the umbilicus. There is very often repeated

* For an elaborate article on the chemical relation of water to lead, see *Schmidt's Jahrbücher*, cxliv. 379.

† Chronic lead-poisoning is produced much more frequently by insoluble than by soluble compounds of lead, and it is probable that any saturated preparation may cause it. Thus, chromate of lead has killed numbers of people. See *Medical News*, ii. 1887 also *Therap. Ges.*, iv.

retching and vomiting. The walls of the abdomen are retracted, rigid, knotted; the bowels are obstinately costive; the tongue is contracted and whitish, the appetite gone, and the thirst sometimes excessive. Neuralgic pains in the thorax and in the extremities are of frequent occurrence. In some cases the conjunctiva is distinctly icterode. This condition, which is known as *colic pictonum*, or *lead colic*, may after a time abate, and the patient convalesce; more usually, however, the attacks recur from time to time, becoming gradually less severe and distinctive, and the patient gradually passes into chronic lead-poisoning. Occasionally the colic increases in severity; sometimes the course of the disease is interrupted by various violent accidents.

The cases of *chronic lead-poisoning* vary so much in their symptomatology as almost to baffle concise description. It has seemed to me that the symptoms can best be studied by arranging the cases in groups, but it must be remembered that in nature not only do these groups shade into one another, but also that there are all kinds of mixed cases,—cases which offer simultaneously or successively symptoms of two or more of these various groups.

The first group contains the great bulk of cases of chronic lead-poisoning, at least as seen in this country. The symptoms consist of failure of health, more or less digestive disturbance, and double wrist-drop,—i. e., paralysis of the extensor muscles of each hand. Not rarely, the only noticeable symptom is the wrist-drop, the general health seeming to be very good. The true nature of such cases can usually be at once recognized by the bilateral character of the wrist-drop, cerebral and pressure paralyses being almost invariably unilateral. I have seen, however, bilateral pressure palsy, and also one or two cases of unilateral plumbic wrist-drop, due to a local absorption of lead, in an artisan whose hand was much of the time in a preparation of the metal. Similar cases have been recorded by Dr. Manouvriez (*L'Intoxication Saturnine*, Paris, 1874; see also *La France Med.*, 1882, i. 829). The wrist-drop may exist alone, but not rarely there is with it anæsthesia of the affected part, or sometimes of the shoulders or other unparalyzed portion of the body. When the paralysis is complete, the electro-contractility of the muscles is in great part or altogether absent.

The rarer forms of chronic lead-poisoning may be divided into the cerebral, the periphero-spinal, and the nutritive.

In the cerebral cases should be included those which are commonly spoken of as *encephalopathia saturnina*, or *saturnine cerebritis*, in which the violent brain-symptoms may develop with great suddenness, or may be preceded by some days of headache, giddiness, sleeplessness, disturbed vision, strabismus, tinnitus aurium, psychical aberration, or other prodromes of brain disturbance. Delirium, which is among the chief manifestations of the fully-formed condition, may be mild, but is often maniacal; stupor may replace or alternate with it; and violent epileptiform convulsions, ending in coma, are not infrequent. These convul-

sions are usually the precursors of death, but recovery may occur even after the most severe symptoms. (Case: See *Charité-Annalen*, ix. 159.)

Without the development of such severe symptoms, headache, loss of memory, giddiness, somnolence, hemianæsthesia, disturbance of the special senses, aphasia, monoplegia, hemiplegia, or multiple cerebral palsies may occur during chronic lead-poisoning. Death, preceded by severe cerebral symptoms, may take place without organic lesion; but usually, when focal symptoms have been present, localized alteration of brain structure, secondary to diseases of the cerebral vessels, or to chronic inflammation of the brain or its membranes, can be detected. Sometimes the cerebral symptoms are uræmic; indeed, true plumbic encephalopathy and plumbic uræmia from contracted kidney may coexist. Again, the more serious affection may be masked by a saturnine hysteria, since cases have been reported by Charcot and by Dutil, in which hysterical hemianæsthesia, amaurosis, anosmia, loss of sense of taste, and other cerebral symptoms, have been the outcome of a major hysteria due to chronic lead-poisoning. Such cases as these probably only occur in individuals of previously hysterical temperament, and must be extremely rare in persons not of the so-called Latin race.

Disturbances of vision are so frequent and so marked in lead-poisoning as to deserve special mention. The amblyopia may come on slowly or suddenly; it may be partial or it may be complete; it may coexist with kidney disease, or may be entirely independent of the latter; associated with it may be a true optic neuritis or a true optic atrophy; but, on the other hand, it may exist without demonstrable disease of the optic nerves. It is undoubtedly often due to a disease of the optic nerves themselves, but the occurrence of homonymous hemianopsia in some cases seems to demonstrate that the blindness may be of centric origin. Strabismus from paralysis of the external rectus or other ocular muscle is sometimes of saturnine origin.*

The second group of cases of chronic lead-poisoning are those in which the nerve-symptoms apparently originate below the cerebrum. Among these may be mentioned cases such as have been reported by Putnam, by Tisier, by Raymond, and by G. L. Walton, in which the phenomena resemble those of locomotor ataxia, except in the presence of tenderness over the nerve-trunks, preservation of the tendon reflexes, or some other atypical symptoms. I have myself seen several cases in which the symptoms resembled those of an acute poliomyelitis, consisting chiefly of widespread paralysis with rapid wasting of the muscles. These cases usually can be differentiated by the presence of violent neuralgic pains, paralysis of the bladder and rectum, or other atypical symptoms. Similar to these cases are those spoken of by Dr. G. Lyon

* For discussion of details, see Bean, *Arch. Gén.*, 1843; Manouvrier, *Arch. de Physiol. Norm. et Patholog.*, 1879, p. 411; 1876, p. 762; A. De Courcy, *De l'Hémianæsthesia saturnine*, Paris, 1875; Proust, *Progrès Méd.*, 1879, vii. 546; Debove, *Ibid.*, 99, 117; Alex. Westphal, *Archiv für Psychiatrie*, xix., 1887-88.

(*Gaz. de Hôpitaux*, 1889), in which a rapid general paralysis spread from part to part, until at last aphonia and dyspnoea, and even death from asphyxia, resulted. Severe intractable chorea has been produced by lead. Disturbances of sensation may occur in lead-poisoning; anæsthesias are, perhaps, not very rare, and violent neuralgic pains, probably due to neuritis, may be the chief manifestation. In a case in which my diagnosis was confirmed by finding lead in the drinking-water and in the urine of the patient, the symptoms were intense general pruritus, with violent neuralgic pains shooting through the rectum and the urethra, coming on at night and producing an insomnia which appeared to be unconquerable. The lesion in most of these motor and sensory cases is probably in the nerve-trunks, and the very rapid pulse seen in some of them may be due to disease of the vagi, since Prevost and Binet have found pronounced degeneration of these nerves (*Rev. Med. Suisse Rom.*, ix., 1889).

The third group of cases are those in which the poison chiefly expends itself upon glandular or visceral organs, or in producing widespread nutritive changes. It would seem that almost any of the vital structures may undergo degeneration. Professor Potain (*La Semaine Médicale*, vol. viii., 1888) reports a case of saturnine cirrhosis of the liver; while Dr. Valence (Nancy, *Thesis* 266, 1888) details a peculiar plumbic parotitis. Rudolf Maier (*Virchow's Archiv*, xc.) has found in poisoned animals atrophic degenerations of the intestinal glands and walls, and there can be no doubt that similar alterations are one cause of the emaciation and anæmia in old cases of human plumbism.

Of great frequency and importance are the lesions produced by lead in the kidneys. It must be remembered that temporary albuminuria may occur in lead-poisoning without serious implication of the kidneys; while, on the other hand, fatal nephritis may exist when there is no albumen in the urine (Dr. Lancéreaux, *Trans. Internat. Med. Congress*, 1881, ii. 191). A persistent low specific gravity of the urine in lead-poisoning is a symptom of the utmost gravity. Goepfert (*Zeitschrift f. Klin. Med.*, v. 161) confirms the observation, previously made by Olivier, that in temporary plumbic albuminuria many isolated kidney epithelial cells may often be found in the urinary sediments; and it is evident that a persistence of this condition must end in chronic renal disease. After death, which may be induced by uræmia, the kidneys are found contracted, granular, with excessive development of the fibrous tissue (followed by contraction) and great thickening of the walls of the blood-vessels: these changes are identical with those of contracted kidney produced by gouty and other irritant poisons. As Ellenberger and Hofmeister have shown that the lead is chiefly eliminated by the kidneys, the frequency of plumbic nephritis is easily explained; but it is not readily perceived why it is so frequently associated with an arthralgia whose course and lesions closely simulate those of chronic gout. Garrod (1859), Dickinson, Lancéreaux, Rosen-

stein, Leyden (*Zeitschrift f. Klin. Med.*, 1884, p. 881), and other authors have reported so many cases of this association of renal and gouty manifestations that it can scarcely be doubted that the plumbism is the cause of the gouty symptoms, and not simply a complication of gout.*

There are certain cases of lead-poisoning which do not conform to any of the types as yet given. Among these very irregular cases may be mentioned those reported by Dr. E. Levy (*Schmidt's Jahrb.*, Bd. clii. p. 250), in which acute asthma was produced by the inhalation of the dust of white lead. Again, chronic saturnine asthma is sometimes seen in feeble, narrow-chested people. Professor James J. Putnam (*Boston Med. and Surg. Journ.*, Feb. 1893) calls attention to the fact that in lead-poisoning of children the legs and feet are commonly paralyzed. Dr. Pagliano (*Marseille Med.*, xxviii., 1891) has reported a case of saturnine facial palsy. Upon pregnant women the influence of the poison is very deleterious, and, as was shown by Dr. Constantine Paul (*Archiv. Gen.*, 1860, vol. xv.), it very commonly produces the early death of the fœtus. Legrand and Winter (*Compt.-Rend. Soc. Biolog.*, 1889) found in such a fœtus not only the lesions of chronic lead-poisoning but also the metal itself in the liver and in the kidneys.

As any of these obscure manifestations of lead-poisoning may exist, and even prove fatal, without a distinct history of other more characteristic phenomena, great care is sometimes necessary to avoid being misled, and not rarely the true nature of saturnine epilepsy or of saturnine albuminuria is overlooked. Hence the importance of the *blue line upon the gums where they join the teeth*, which is very common in persons suffering from lead-poisoning. It is said to be the result of a formation in the walls of the capillaries of the sulphide of lead. As was first pointed out by Dr. J. J. Putnam (*Trans. Amer. Neurol. Assoc.*, 1883), chronic lead-poisoning may exist without this blue line upon the gums. Under such circumstances, if the symptoms be obscure the diagnosis can be established only through a chemical examination of the urine.† The practitioner should see that the urine which is to be sent to the chemist for examination be slightly acidified, that directly after passing it be put in flint glass bottles, and that it be at least a quart in quantity.

In those cases of lead-poisoning which pursue a slow course to death, the paralysis involves after a time the extensors of the lower as well as of the upper extremities, epileptic paroxysms occur at intervals, rack-ing pains shoot through the limbs, points of cutaneous anæsthesia appear, and often albuminuria aids in producing the fatal issue. Gradually the patient becomes more and more cachectic, general œdema and

* Consult *Deutsch. Med. Wochenschrift*, 1883, pp. 185, 351; 1884, p. 129; also Dr. Paul Muehsch, *Die Bleivergiftung*, Berlin, 1883. I have myself seen one case.

† For an elaborate discussion, see Leading Article in *Therap. Gaz.*, Dec. 1887; also *Therap. Gaz.*, iii. 813, also iv. 93.

the whitened skin betray the increasing anæmia, the paralysis extends from muscle to muscle, locomotion becomes impossible, and, if a convulsion or other accident do not close the scene, death at last takes place from loss of power in the respiratory muscles. M. Malassez has found that in the anæmia of lead-poisoning the red globules are not only diminished in number but also increased in size (*Archives de Physiologie*, 1874, p. 50).

After death lead has been frequently detected in the tissues. Heubel found most of it in the bones, and less in the muscular than in the nervous system (*Virchow und Hirsch's Jahrbücher*, 1871, vol. i. p. 316). Professor Chatin (*Comptes-Rendus Soc. de Biol.*, 1862, iv. 84) obtained from the cervical spinal cord three in one hundred and fifty parts. In the studies of Ellenberger and V. Hofmeister (*Arch. f. Wissen. und Prakt. Thierheilk.*, x. 216) the liver and kidneys were found to contain the most lead, after them the bones, then the nerve-centres, and finally the flesh. Prevost and Binet (*loc. cit.*) found the lead in all the tissues, but believe that it especially accumulates in the kidneys.* G. N. Pitt (*Trans. Path. Soc.*, London, 1891, xli.) reports finding over forty-seven grains of the lead sulphite in nine inches of the colon.

The electro-muscular contractility is affected very early in lead-poisoning, and may be lost before the voluntary movements. It is stated by M. Raymond that the short extensor of the thumb preserves its function when all the other extensor muscles are paralyzed. The paralyzed muscles are finally exceedingly wasted, and their structure may be so totally destroyed that scarcely a single striated fibre can be found. The nerve-trunks are lessened in size, in many of their tubules

* A question of the most serious importance, which at present we are not able to answer positively, is as to whether sclerosis, neuritis, and other chronic affections of the nervous system which have been reckoned as idiopathic or of unknown origin, are not frequently the outcome of an entirely latent lead-poisoning. In a remarkable paper, Dr. J. J. Putnam, of Boston (*Trans. Assoc. American Physicians*, ii.), describes cases entirely apart from recognized types of lead-poisoning, in which the metal was found in the urine. These cases may be grouped as follows: 1. Trembling of hands; sense of coldness and numbness in toes; lancinating pains in legs; fatigue on exertion. 2. Marked progressive spastic paraplegia, with myosis and pupillary reactions; ataxia and some atrophy of hands. 3. Progressive weakness and stiffness in legs, with diffused and almost universal pains; marked tremor. 4. Temporary pain in chest, with slight dyspnoea; progressive numbness, heaviness, and weakness in legs. 5. Numbness in feet and legs, with impairment of strength; tremor of hands and tongue; some wasting of small muscles of hands; temporary retention of urine. Closely connected with this subject is the question whether lead may not be for a length of time in the system and appear in the urine without doing injury to the health. In a recent paper (*Boston Med. Surg. Journ.*, vol. cxxiii., 1890), Dr. Putnam brings forward more facts, whose import is at present very doubtful. In an examination of the urine of sixty-eight persons, presenting no evidences of any disarrangement of health, lead was found in the proportion of about seventeen per cent., while the urine of thirty-six persons suffering from chronic and subchronic affection of the nerves, nerve-centres, and spinal cord contained lead in the proportion of fifty per cent. In the last group were cases of tremors with debility, of chronic multiple neuritis, multiple sclerosis, spastic paraplegia, muscular atrophy, epilepsy, sciatica, digestive disorders, etc. (*Boston Med. and Surg. Journ.*, vol. cxxi., 1889). One cannot help suspecting that, owing to defective water-supply, Bostonians are especially prone to contain lead.

the modulla has been replaced by fatty granules, and in some cases every trace of the tubules has disappeared and the nerve been reduced to a fibrous cord. According to the researches of M. Dégérine (*Comptes-Rendus Soc. de Biol.*, 1880), the first appearance of change in a nerve-trunk consists in the myeline becoming broken up into blocks, and the nature of the change is a commingling of a parenchymatous and an interstitial neuritis, which both Dégérine and Vulpian have traced upwards as far as the anterior spinal roots. Lancéreaux (*Gaz. Méd. de Paris*, 1862, 1871), Westphal (*Arch. f. Psych.*, iv. 776), Friedländer (*Virchow's Arch.*, lxxv. 24), and others, may be cited as having found very distinct peripheral lesions in lead-poisoning. Whether these lesions begin in the nerve or in the muscles cannot be considered as determined. Birdsall (*N. Y. Med. Record*, March, 1882) reported a case of what he believed to be a plumbic myositis, and Goubault (*Le Progrès Méd.*, 1880) describes primary alteration in the nerves, similar to those seen after section, as occurring in poisoned guinea-pigs, while MM. Debove and Reaut (*Le Progrès Méd.*, 1876, 151) describe the first changes as resembling those of subacute myositis, and Friedländer emphatically asserts that lessening in the size of the muscular fibres and multiplication of the muscular nuclei precede the nerve-degeneration. On the other hand, Vulpian (*Maladies du Système Nerveux*, 1879), Monakow (*Arch. f. Psychiat. und Nervenkr.*, x. 495), Oeller (*Festschrift dem Aerztl. Verein d. Munchen*, 1883), and a number of other observers (for references, see *Arch. f. Psychiat. und Nervenkr.*, xvi. 477) have noticed structural changes (poliomyelitis, capillary hemorrhages, etc.) in the spinal cord of men dead of plumbism; while Popow (*Virchow's Archiv*, Bd. xciii. p. 351) found that when guinea-pigs were rapidly poisoned (six to eight days) with lead there was produced a central myelitis, which first affected the large cells of the gray matter, and afterwards involved the white matter, the peripheral nerve-filaments remaining normal. There is, however, no real contradiction, as Popow believes, between his observations and those of Goubault, for the latter (*Arch. de Physiol. Norm. et Path.*, 1873) poisoned his animals very slowly (six months), and it is not improbable that the rapidity of the poisoning should have influence upon the seat of the lesion. As already stated, the symptoms of plumbism may exactly simulate those of general poliomyelitis, and both Dégérine and Leopold Stieglitz (*Arch. f. Psych.*, 1892, xxiv.) found degeneration of the motor cells. Karl Schaffer believes that two sharply separated forms of degeneration of the nerve-centres occur in chronic lead-poisoning,—one consisting of a minutely granular destruction of the protoplasm, the other of the homogenization of the contents of the cell (*Ungar. Archiv f. Medizin*, Bd. xi., 1893). The evidence at present indicates that lead is capable of producing a peripheral neuritis, and also a centric poliomyelitis, which may or may not coexist in an individual case; the probabilities being in favor of a peculiar peripheral neuritis, as the primary lesion of ordinary

plumbic wrist-drop (see paper by Professor Schultze, *Arch. f. Psychiat. u. Nervenkr.*, 1885, xvi. 809; also Provost and Binet, *loc. cit.*). Hemorrhages into the nerve-centres sometimes occur (*Le Progrès Méd.*, xii. 827). There seems to be no doubt that lead really affects the nutrition of almost all of the higher tissues. In saturnine encephalopathy changes have been found in the ganglionic cells as well as in the neuroglia, with stenosis of capillaries and general shrinkage of the cortex (see Dr. O'Carroll, *Brit. Med. Journ.*, i., 1893). Marked alterations are not rare in the kidneys and other glandular organs, and general fibrosis of the blood-vessels is probably more or less developed in every slowly fatal case of chronic poisoning (case, Fisher, *Amer. Journ. Med. Sci.*, civ., 1892).

The excretion of lead with the gall is very active, but it is probable that it chiefly escapes from the body with the urine. The elimination seems to be capricious, and much affected by iodide of potassium (Melsens, *Ann. Phys. et Chim.*, xxvi.; Pouchet, *Arch. de Physiol.*, xii. 74; Annuschat, *Arch. Exper. Path.*, Bd. x.; Pouchet, *Arch. de Phys. Norm. et Path.*, 1879) and by other influences.*

The treatment of chronic lead-poisoning evidently arranges itself under three indications: 1st, to prevent the ingestion of more of the poison; 2d, to aid in the elimination of that in the system; 3d, to relieve symptoms and restore lost functions. In lead-colic both of the last two indications are met by purgatives, to which opium should be added to relieve pain. It is often necessary to use the most powerful drastics, such as croton oil; but senna, salts, and other of the milder cathartics should always be tried first. Alum, it is asserted, acts in some unknown way as a specific in lead-colic, and from twenty to sixty grains of it may be given four or five times a day; but my own experience is not favorable to its use. In the more chronic forms of lead-poisoning, to fulfil the second indication baths of sulphuret of potassium should be employed, and iodide of potassium be administered internally.† As the result of special investigation, Oddo and Silbert (*Rev. de Méd.*, Paris, xii., 1892) conclude that the elimination of lead through the skin in chronic lead-poisoning is important, and that it is facilitated by injections of pilocarpine, and that the sulphur baths are

* Lead has been found in the urine of man or of the lower animals by Orfila, Lewald (*Ausscheidung der Arzneimittel*, Breslau, 1861), Gumerow (*Virchow's Archiv*, Bd. xxi.), Annuschat (*Arch. f. Exper. Path. und Pharm.*, x. 260), and Oettinger (*Wiener Med. Wochenschrift*, 1858); also in my clinical service at the University Hospital.

† As the result of a careful series of analyses, Dr. J. D. Mann (*Brit. Med. Journ.*, vol. i., 1893) concludes that in chronic lead-poisoning there is a great fluctuation in the elimination of lead; that iodide of potassium has no real effect in increasing the elimination; that lead is eliminated from the intestines even more freely than from the urine; and that the previous contrary results obtained by investigators have been due to chance coincidences of the iodide treatment with increase of the lead excretions from other cause. He recommends especially general massage, and confirms to some extent the assertions of Tedeschi, that this massage increases remarkably lead elimination.

valuable in the treatment of chronic lead-poisoning. The bath should be given (Dr. A. Eulenburg, *Deutsch. Arch. f. Klin. Med.*, Bd. iii. p. 506) in a wooden tub, two or three times a week, and should contain six or seven ounces of the salt. The patient, during the half-hour of his continuance in it, should be from time to time well rubbed with a coarse towel. On coming out he is to be thoroughly washed with warm soapsuds. The dose of the iodide should be from fifteen to twenty grains, administered after meals, in dilute solution. A case is reported in the *London Lancet*, 1876, ii. 53, in which galvanic baths were used successfully, the patient being placed in the bath and the positive pole of a twenty-eight-cell battery applied to the nape of the neck, the negative to the feet. When severe cerebral symptoms arise, treatment is of little avail, and should be largely expectant.* In cases of lead-poisoning in which the symptoms resemble those of acute poliomyelitis I have used ascending doses of strychnine with most extraordinary results, rapidly-deepening paralysis being almost at once controlled. It is essential that the strychnine be pushed to the point of systemic intolerance. It is best to administer it by the mouth, or if used hypodermically it should be given at least twice a day. It may possibly prove of value in other acute forms of lead-palsy.

The local use of electricity is exceedingly important to restore the lost function of nerve and muscle. When the faradic current elicits a response, it should always be employed; but in some cases (Meyer's *Electricity*, New York, 1869, p. 284) the continued current retains its power after the induced has lost all its influence. The rule is always to apply that current which causes contraction; if both fail, the continued current should be used, the poles being reversed at intervals of four or five seconds. The electrical sittings should be tri-weekly, each lasting about fifteen minutes, and they should be persevered in for months. I have seen great improvement in a case which for the first four months yielded no results; indeed, long after voluntary movement had in great measure returned, no form of electricity would cause contraction of the affected muscles.†

* It seems doubtful whether the sulphur baths really aid elimination, but I have certainly seen good follow their use. It has been denied that the iodide acts; but cases are reported in which lead was not in the urine before, and was after the administration of the drug (see *Brit. Med. Journ.*, 1880, ii. 1034). Moreover, Dr. John Marshall (*Therap. Gaz.*, iv. 97) has shown by actual experiment that potassium iodide in solution has an action on the insoluble carbonate and phosphate of lead, with the formation of a soluble lead compound,—double iodide of lead and potassium; and therefore, if lead taken into the system be deposited in the tissues as insoluble carbonate or phosphate, these latter compounds, on the administration of potassium iodide, will be decomposed, with the production of a soluble lead compound, and consequently a more rapid elimination of the lead will occur.

† Professor M. Semmola (*Bull. Acad. de Méd.*, xlviii., 1892) claims that chronic plumbism can be readily cured by the elimination of the metal from the urine under the influence of a constant galvanic current. He applies the positive pole upon the tongue and the negative pole over the region of the kidneys for a while; later, places the positive pole upon the sides of the vertebral column and the negative pole upon the abdomen, keeping up the application

PHYSIOLOGICAL ACTION.—The symptoms of acute lead-poisoning are chiefly due to its local irritant action, but those of chronic poisoning are of wider significance. How the lead is absorbed to produce them is uncertain,—probably as an albuminate. All the compounds of lead and albumen as yet discovered by the chemist are, however, precipitated by alkaline carbonates, and cannot therefore exist in the blood.

The symptoms of chronic lead-intoxication to be accounted for are the colic, the anæmia and wasting, the palsies, and the rare cases of cerebral symptoms or of kidney-degeneration. In explaining them we are chiefly indebted to the researches of Dr. Ernest Harnack (*Archiv f. Experim. Path. u. Pharm.*, 1878), who employed the compound of lead and ethyl, first discovered by Loewig. When this is injected into animals in large quantities it causes a rapidly fatal train of symptoms evidently due to the action of the compound itself. When, however, the introduction into the system has been slow, a chronic poisoning is produced by the lead set free in the blood and tissues.

Under these circumstances a constant symptom, in both dogs and rabbits, is diarrhœa, due to a violently increased peristalsis, with, in the dog, occasional attacks of colic. As both the diarrhœa and the excessive peristalsis are arrested by atropia, they are probably the result of an action upon the intestinal ganglia. The colic in man is probably due to the excitement becoming so intense as to cause spasmodic contraction of the muscular coat of the intestine and consequent arrest of peristalsis, obliteration of the intestinal lumen, and constipation. If such be the case, large doses of belladonna should at once give relief. Dr. Harnack found that in dogs the lead ethyl produces violent excitement, with chorea, convulsions, etc., evidently due to an exciting or irritant action upon the cerebrum, and believes that this explains the saturnine cerebral cases sometimes seen in man.

The chief symptom of the poisoning in frogs was a progressive palsy of muscular origin. The muscles became exhausted on repeated galvanization much more rapidly than is normal, and after death was incapable of undergoing complete post-mortem rigidity. The peripheral nerves appeared to have escaped entirely. The heart-muscle shared the fate of the voluntary muscles. The muscular action of the poison was excessively pronounced in rabbits, but was feeble in dogs and cats. Different results have, however, been arrived at by Dr. H. von Wyss (*Virchow's Arch.*, Bd. xcii.), who found that the loss of reflex activity, etc., in the frog was not prevented by tying an artery so as to protect the leg from the poison, and that the protected muscle lost its power of responding to electrical stimulation just as fast as did the one reached by the lead. He concludes, therefore, that the paralysis is of centric

for five to twenty minutes each day, using a current from one hundred to one hundred and fifty milliamperes. He affirms that in cases in which no lead could be found in the urine after three or four days of treatment the lead could be readily detected and that its quantity gradually increased.

origin. Curci is stated to have proved that lead exerts an irritant influence upon the peripheral branches and ganglionic centres of the pneumogastric (*Gaz. Hebdom.*, 1883, 552; from *Gazzetta degli Ospitali*, March, 1883).

The pulse in lead-colic is usually very hard and tense. Sphygmographic studies made of it by August Frank (*Deutsch. Arch. Klin. Med.*, xvi. 422) and Ernest Bardenhewer (*Berlin. Klin. Wochenschr.*, 1877, 126) have been thought to indicate a condition of general arterial spasm, and have given rise to the very improbable theory that the colic is caused by intestinal anemia from vaso-motor contraction. Bardenhewer found that hypodermic injections of pilocarpine relieve simultaneously the pulse and the colic, precisely as Harnack discovered that atropine does. Harnack, however, found that in rabbits and dogs the lead ethyl has no action upon the circulation except by direct influence on the cardiac muscle, and that it does not produce vaso-motor spasm. He is probably correct in believing that the pulse of lead-colic is due to an overfulness of the blood-vessels produced by an expulsion of the blood from the intestines by the severe spasm of their coats. According to the researches of Ellenberger and Hofmeister, in the sheep toxic doses of lead greatly depress the elimination of urea.

The following preparations of lead are official in the United States Pharmacopœia:

PLUMBI OXIDUM—LEAD OXIDE. U.S.

Litharge, which is prepared by blowing air through melted lead, occurs in small yellowish or orange-colored scales, which are insoluble in water and alcohol, but are soluble in acetic or dilute nitric acid and in warm solution of the fixed alkalies. It is rarely used as a desiccant astringent powder for ulcers, but its chief employment in medicine is as the basis of the following preparations:

Emplastrum Plumbi, or *Lead Plaster*, U.S., is made by boiling litharge, olive oil, and water together. Glycerin is set free, and the oleomargarate of lead is formed. Lead plaster occurs in grayish, cylindrical rolls, which become adhesive at the temperature of the body, and, spread upon kid, is sometimes used as a protective to parts exposed to pressure, or to superficial ulcers or abrasions. *Emplastrum Resinæ*, or *Resin Plaster*, U.S., or *adhesive or sticking plaster*, is made by incorporating resin with lead plaster, and, spread upon linen, is much used in surgery for mechanical purposes. *Emplastrum Saponis*, or *Soap Plaster*, U.S., is made by the addition of soap to lead plaster. It is employed chiefly as a protective.

PLUMBI ACETAS—LEAD ACETATE. U.S.

Sugar of lead is made by the action of acetic acid upon litharge, or upon sheets of lead exposed to the air. It occurs in transparent, acicular, often aggregated, crystals, of a sweet, styptic taste. It is soluble

in water, to which it usually imparts a slight milkiness. From its solution it is precipitated black by sulphuretted hydrogen, white by soluble carbonates, chlorides, and sulphates, and bright yellow by iodide of potassium. It is also incompatible with the mucilage of slippery elm, but scarcely so with that of flaxseed or of pith of sassafras.

THERAPEUTICS.—A solution of acetate of lead is used very largely in acute external inflammations as a sedative and astringent lotion. Although chemically incompatible, it is frequently combined very advantageously in these cases with opium. As a too concentrated solution acts as an irritant, the strength for use on the skin should not exceed ten grains to the ounce. In diseases of the eye it is condemned by oculists, because when there is any abrasion of the cornea it is very prone to deposit an opaque film.

Internally, acetate of lead has been employed very largely in hemorrhage: indeed, Professor George B. Wood commends it as the most valuable of all astringents in hæmoptysis (*Therapeutics*, vol. i. p. 158). I think it is now, however, rarely given for this purpose. Its chief use at present is in diarrhœa. On account of its sedative properties, when the purg'g is attended with inflammation it is the most serviceable of all the astringents; and, owing to the promptness of its action, it is also very valuable in cases with profuse serous discharges. In dysentery it is very useful whenever the discharges have become copious. The dose is from two to five grains, always in pill, repeated *pro re nata*.

LIQUOR PLUMBI SUBACETATIS, U.S.—The *Solution of Lead Subacetate*, or *Goulard's Extract*, as it is sometimes called, is a colorless, limpid liquid, of a sweetish, astringent taste. It is made by boiling litharge in a solution of acetate of lead, and has an alkaline reaction. When exposed to the air, it rapidly absorbs carbonic acid and deposits carbonate of lead, the neutral acetate being left in solution. In its action upon the human organism, Goulard's extract resembles very closely the simple acetate of lead; but it is never used internally. Externally, it is a favorite application in cases of sprains or bruises, as well as in superficial inflammation. For this purpose it requires dilution, and from a fluidounce to four fluidounces of it may be added to a pint of water. When used upon a raw surface, the strength should not be so great. A sedative poultice, which is very highly recommended by some physicians in the early stages of inflammation, may be made by saturating crumbs of stale bread with Goulard's extract diluted with four to six times its bulk of water. This poultice must be applied cold. The officinal *Liquor Plumbi Subacetatis Dilutus*, or Diluted Solution of Subacetate of Lead, is of the strength of three parts in a hundred. It is too weak to be of much value.

PLUMBI CARBONAS, U.S., or *Lead Carbonate*, is a heavy, white, tasteless powder, insoluble in distilled water, but slightly soluble in water

containing carbonic acid. It is used solely as an external sedative application. Rubbed up with linseed oil, it constitutes white-lead paint, and in this form, or in that of the ointment (*Unguentum Plumbi Carbonatis*, U.S.), it is a most efficient dressing for fresh burns. Care must be taken in its use, however, when a large surface is involved, as lead-colic has been caused by its absorption.

PLUMBI NITRAS, U.S., or *Lead Nitrate*, occurs in white, nearly opaque, octahedral, very heavy crystals, soluble in two parts of water at 59° F., and in 0.75 part of boiling water; almost insoluble in alcohol. It is used chiefly as a disinfectant. Dissolved in water, it forms *Ledoyen's Disinfectant Solution*. It acts by decomposing the sulphuretted hydrogen, itself being converted into a lead sulphide. It is said to attack actively the soldering of pipes (*Report on Hygiene, U. S. Navy*, 1879). Its chemical reactions are similar to those of the acetate, from which it may be distinguished by a mixture of it and sulphuric acid striking a red color with morphine. Lead nitrate is frequently used in *onychchia maligna*. The dead part of the nail should be cut away, and the powdered nitrate thickly sprinkled over the surface; after a few days the slough separates, leaving a clean surface, upon which the new nail usually soon forms. Sometimes more than one application of the remedy is required.

BISMUTHUM—BISMUTH.

The metal bismuth is never used in medicine in its simple or metallic form.

BISMUTHI SUBCARBONAS—BISMUTH SUBCARBONATE. U.S. ($\text{BiO}_2\text{CO}_3 \cdot \text{HO} - 2\text{Bi}_2\text{O}_3\text{CO}_3, \text{H}_2\text{O}$.)

A white or yellowish-white powder, tasteless and odorless, totally insoluble in water, soluble with effervescence in dilute nitric acid. **BISMUTHI SUBNITRAS**, or **BISMUTH SUBNITRATE**, U.S., is a heavy white powder, odorless, with a faint acid taste, and a decidedly acid reaction when applied to moistened litmus-paper, almost insoluble in water, soluble without effervescence in nitric acid. The official processes for the preparation of these salts are too complicated for discussion in a work like the present, the object of the various stages being to get rid of arsenic, which contaminates all the bismuth ores of Europe. Of late years the South American bismuth has been introduced into commerce, and, as it contains no arsenic, commercial bismuth preparations are no longer contaminated.

PHYSIOLOGICAL ACTION.—The actions of the subnitrate and of the subcarbonate of bismuth are so exactly similar that they can practically be considered as one. Orfila and others of the older observers attributed to bismuth violent irritant properties, reporting severe symptoms and even death after its ingestion. These results were, however, due not to

the bismuth, but to the arsenic with which it was contaminated. The soluble preparations of bismuth are, it is true, active irritant poisons (see *BISMUTHI CITRAS*), but the insoluble subcarbonate and subnitrate, when pure, have practically no irritant influence. It was formerly denied that they are dissolved at all in the alimentary canal, but it is now certain that they are very slowly absorbed, and as slowly eliminated. Harnack affirms (*Arzneimittellehre*, 1883, p. 383) that the metal has been found by Orfila in the liver, spleen, and urine, and by Lewald in the milk. M. M. Bergeret and Mayençon (*Journal de l'Anatomie*, 1873, p. 212) state that when the subnitrate of bismuth is administered the metal can always be detected, after a few hours, in the urine. They have also discovered it in the serous exudation of dropsy, and have proved that when a few grains of the salt mentioned are given to rabbits, in from twenty to thirty minutes it can be found in the urine, kidneys, spleen, blood, and muscles, and even eight days after the administration can be detected in all the tissues. Five days after the exhibition of a gramme of the subnitrate to a man, they found traces of the metal in the liver and kidneys; but the analysis of the body of a woman dead sixty-two days after the ingestion of two grammes yielded only negative results. Professor E. S. Wood also has detected bismuth in the urine four weeks after its last exhibition (*Trans. Amer. Neurolog. Assoc.*, 1883, p. 23).

The discovery by Theodore Kocher (*Volkmann's Klinischer Vortr.*, No. 224) that the most insoluble bismuth preparations are actively antiseptic led to their use in surgery, and to the further discovery that when applied in very large quantities to extensive wounded surfaces they are capable of yielding so much bismuth to absorption as to produce a poisoning, which is characterized by acute stomatitis with a peculiar black discoloration of the mucous membrane, usually beginning upon the borders of the teeth, but spreading over the whole mouth, followed by an intestinal catarrh with pain and diarrhoea, and in severe cases with desquamative nephritis, as shown by albuminous urine and epithelial tube casts. (For cases, see Kocher, *loc. cit.*, also Professor Petersen, *Deutsches Med. Wochenschr.*, June 20, 1883.)

That bismuth is capable of acting as a poison in the lower animals has been abundantly proven by the experiments of F. Balzer (*Compt. Rend. Soc. d. Biolog.*, Paris, 1889) and of P. Daleché and E. Villejean (*Bull. Gen. de Ther.*, lviii., 1888), which show that whether given by the mouth or hypodermically, repeated large doses of it produce gradual failure of strength, a peculiar stomatitis, and evidences of gastro-intestinal irritation, with death from exhaustion. Balzer states that the stomatitis which it causes differs from the stomatitis of pytalism in the tendency to rapid gangrenous change; and also that the bismuth is eliminated with the saliva, bile, and urine, but has a distinct tendency to accumulate in the tissues.

THERAPEUTICS.—When brought in contact with the mucous membranes, the insoluble preparations of bismuth, by virtue of their weight,

tend to adhere and to act as protectives; they also exert an antiseptic influence, and by their slow absorption produce a persistent,—peculiarly persistent,—sedative, astringent action. They are, therefore, of great service in the treatment of irritations and inflammations of those mucous membranes with which they can be brought in contact. Thus they are useful to allay vomiting dependent upon gastric irritation. In simple neuralgic gastric pain following eating, especially when occurring in feeble, badly-nourished subjects, bismuth is often of great service; and even in carcinoma it may palliate by alleviating pain and vomiting. In pyrosis it is sometimes successful; in gastric and enteric catarrhs it is a standard remedy. In simple diarrhœa of irritation, and in the chronic diarrhœa of camps, the bismuth preparations are often very efficient; and in the chronic bowel complaints of children, especially as seen in the summer season, given with pepsin, they are almost invaluable. Bismuth is a very valuable topical remedy in the treatment of mucous inflammations and of ulcers to which it can be applied directly. Thus, in the beginning of a gonorrhœa, the injection every two hours of a mixture containing twenty grains of bismuth to the ounce usually brings immediate relief; in a similar way it may be employed in leucorrhœa and in acute coryza. In Germany it has been to some extent employed as a surgical dressing.

ADMINISTRATION.—In order to get the best attainable results from the use of subnitrate of bismuth it is necessary to vary the dose and method of administration. In stomachic affections from five to fifteen grains may be given preferably when the stomach is empty, in order that the bismuth may be distributed as closely as possible over the gastric mucous membrane. In intestinal diseases from fifteen grains to a drachm may be exhibited from one to two hours after meals at a time when the gastric contents are escaping through the pylorus. Children bear proportionately very large doses: thus, five to ten grains may be given to a two-year-old infant.

BISMUTHI CITRAS, U.S.—The insoluble *bismuth citrate* is not used in medicine, but has been introduced into the Pharmacopœia for the production of the soluble *Bismuthi et Ammonii Citras*, U.S. According to Feder-Meyer (*Inaug. Diss.*, Würzburg, 1879), the *bismuth and ammonium citrate* causes in rabbits violent tremblings with diarrhœa, accompanied after large doses by disturbance of the sensibility and of co-ordination, tetanic cramps, altered respiration (in the beginning accelerated and superficial, afterwards becoming slow), continual lowering of the blood-pressure, and death. The same observer noticed in chronic poisoning similar symptoms with albuminous urine and after death fatty degeneration of the liver, heart, and renal secreting structure. Similar observations were made by Mory, who (*Inaug. Diss.*, Berne, 1883) states that the death in mammals is the result of cardiac paralysis, and that in the advanced stages of chronic poisoning, when the blood-pressure is

very low, it is not elevated by stimulation of the splanchnic nerves nor by asphyxia. W. Steinfeld (*Arch. f. Exper. Path. u. Pharm.*, xx. 41) has obtained in the frog from the administration of ammonio-citrate and ammonio-tartrate of bismuth peculiar tremblings of the voluntary muscles with prolongation of contraction upon stimulation with the galvanic current, and slowing of the heart's beat, also after sufficient doses paralysis of nerves and muscles; effects which he attributes not to the bismuth, but to the acids of the preparations. He states that the proper symptoms produced by the metal only appear after some hours, and consist of motor excitement with reflex cries which are due to irritation of the medulla oblongata. In acutely poisoned mammals he noticed vomiting and purging, convulsions with loss of power, slowing of the pulse, and sinking of the blood-pressure, believed by him to be all of centric origin. In chronic poisoning there was loss of certainty of movement with cardiac depression followed by increasing paralysis, usually ending in death without convulsions. In his studies upon absorption and elimination he found that the ammonio-citrates and ammonio-tartrates are quickly eliminated through the kidneys, so that, as a rule, after from ten to fifteen hours they can no longer be found in the blood, tissues, or urine.

THERAPEUTICS.—I know of no serious poisoning in man by the ammonio-citrate of bismuth, but it is undoubtedly capable of acting as a violent gastro-intestinal irritant. It has none of the peculiar properties which grow out of the insolubility of the subnitrate, but is more astringent, and has been employed to some extent in doses of five grains in *chronic diarrhœa* and in the *acute diarrhœas of relaxation*. It should be administered in a dilute watery solution, repeated every three to six hours *pro re nata*.

CERII OXALAS. U.S.

Cerium oxalate is a white powder, insoluble in water, alcohol, and ether, but soluble in sulphuric acid. It has been employed in medicine quite largely for the relief of vomiting, especially when dependent upon pregnancy or other forms of uterine disturbance. Its action on the economy has not yet been made out, but it may be tried with some hope of success in cases of nervous or dyspeptic vomiting. The dose is one to three grains, in pill, three or four times a day.

ZINCUM—ZINC.

ZINCI SULPHAS—*Zinc Sulphate*, U.S.—*White Vitriol* occurs in irregular white masses, the pure zinc sulphate in minute, transparent, four-sided, prismatic crystals, which effloresce slightly in dry air, and are soluble in 0.6 part of water at 59° F., and in 0.2 part of boiling water, also soluble in about three parts of glycerin; insoluble in alcohol. The taste is styptic and peculiar.

THERAPEUTICS.—Sulphate of zinc is in weak solution a stimulant astringent, in concentrated form an active irritant. Taken in doses of thirty grains it acts as a prompt, efficient mechanical emetic. In smaller doses, of two grains, it is sometimes given in pills as a stimulant astringent in *chronic diarrhœa* with ulceration.

TOXICOLOGY.—Sulphate of zinc in large doses acts as an irritant poison, producing violent vomiting, colicky pains, diarrhœa, prostration, etc. The symptoms which it causes are almost identical with those produced by the corresponding salt of copper. Alkalies and their carbonates are the chemical antidotes to it, producing insoluble precipitates. Eggs and milk should also be exhibited, and the symptoms treated as they arise. Chronic zinc-poisoning, if it really exists at all, is very rare, and the metal seems to be used with impunity in cooking-utensils. Dr. Schlockow, however, affirms (*Deutsches Med. Wochenschrift*, 1879, 208) that zinc-smelters rarely live to be over forty-five,—dying sometimes with catarrh of the bronchial or alimentary mucous membranes, or, in other cases, of a peculiar nervous affection, which commences with burning superficial pains, exalted sensibility, and reflex activity in the legs, and afterwards puts on still more clearly the features of myelitis; and A. Sacher (*Dorpat Thesis*, 1893) finds that intravenous injection of very large doses of zinc salts produces paralysis of the voluntary muscles.

ZINCI OXIDUM VENALE.—Commercial oxide of zinc is a snow-white powder, obtained by burning the metal in the air. It should be used only in pharmacy. The pure oxide (*ZINCI OXIDUM*, U.S.) is made by heating the carbonate until the water and acid are driven off. It is a yellowish-white powder, insoluble in water, but soluble without effervescence in dilute acids.

THERAPEUTICS.—Oxide of zinc is used externally as a mildly astringent, slightly stimulant, and desiccant application in *skin diseases* and to *ulcers*. When given continuously in small doses it is believed to act as a tonic and alterative upon the nervous system. It has also been commended as an astringent in chronic *catarrhal diarrhœa* of adults and infants, and has been largely used in *epilepsy* and in *chorea*. The dose is one to five grains. The ointment (*Unguentum Zinci Oxidi*, U.S.—one part to four of benzoinated lard) is especially useful in chronic *eczema*.

ZINCI CARBONAS PRÆCIPITATUS, U.S.—Precipitated zinc carbonate is intended to replace the old impure native carbonate, *calamine*. It is made by precipitating the zinc sulphate by the sodium carbonate. It is a white powder, closely resembling in its medical properties zinc oxide.

ZINCI ACETAS, U.S.—Zinc acetate is made by the action of acetic acid upon the commercial oxide of zinc. It occurs in white, micaceous

crystals, which effloresce in a dry atmosphere and are very soluble in water. The taste is astringent and metallic. The acetate of zinc resembles in its physiological and therapeutic qualities the sulphate, but is probably somewhat less active. It is chiefly used in collyria (one to two grains to one fluidounce), and as an injection (one to twenty grains to one fluidounce) in *gonorrhœa*.

CADMIUM is employed in medicine to some slight extent in the form of its *sulphate*, which is stated to resemble closely the sulphate of zinc in its therapeutic properties. It has been especially used as an astringent stimulant in collyria, made by dissolving half a grain to four grains in an ounce of rose-water. Strangely enough, some physicians who have employed it state that it has ten times the strength of the zinc salt, others that it is about equivalent to it.

CUPRUM—COPPER.

CUPRI SULPHAS—COPPER SULPHATE. U.S.

Copper sulphate occurs in blue, transparent, slightly efflorescent, rhomboidal prisms, or their fragments. It dissolves, at 59° F., in about 2.6 parts of water and in 0.5 part of boiling water; almost insoluble in alcohol. With ammonia its solution precipitates a bluish-white cupric hydrate, which redissolves when an excess of the alkali is added, forming a rich deep-blue solution.

PHYSIOLOGICAL ACTION.—In very dilute solution the sulphate of copper acts locally as a stimulant and mild astringent; in a more concentrated form it is an irritant; in powder it is a very mild caustic, which is scarcely capable of destroying sound tissue. Taken internally in very small amounts and continuously, it is thought to have a corroborant influence upon the nervous system. Professor Falck (*Deutsche Klinik*, xi., 1859) has found that the sulphate of copper acts upon pigeons, dogs, rabbits, etc., as an irritant neurotic poison, producing great depression of temperature, with progressive general paresis, ending in death, apparently from failure of respiration. When the copper salt was given hypodermically, vomiting was not produced; although when it was exhibited by the mouth, emesis was very violent and persistent. In doses of five to fifteen grains it acts upon man as an irritating emetic, and in larger amounts is an irritant poison.

THERAPEUTICS.—The chief internal use of sulphate of copper is as a mechanical emetic. As it is more irritating than sulphate of zinc, it acts more rapidly and in smaller dose. For the same reason, however, it is not so safe as the white vitriol, and cannot be repeated so freely when its action fails.

As a stimulant and astringent it is occasionally administered, in pill form, in *chronic diarrhœa* with ulceration. In small repeated doses it has been used in various nervous affections with doubtful advantage.

The chief value of the so called "*blue stone*" is as an external application. When applied in solid form to ulcers, it destroys flabby granulations and exerts a powerful excitant influence. Its solution acts more feebly, and is sometimes employed as a dressing for indolent ulcers, but more frequently as a stimulant and alterant to mucous membranes, as in *granular conjunctivitis*.

TOXICOLOGY.—The symptoms of acute copper-poisoning generally come on in about a quarter of an hour after the ingestion of the poison, but may be postponed for from one to two hours. They consist of violent vomiting and purging, accompanied by very severe colicky pains. The matters vomited are greenish or bluish, the stools glairy, mucous, and at times bloody. There is a very strong taste of copper in the mouth, and often constant expectoration; excessive salivation and bronchial secretion are stated by Galippe (*Étude toxicol. sur la Cuivre*, Paris, 1875) to be characteristic. Death may occur in a few hours, preceded by convulsions, paralysis, delirium, anæsthesia, and other symptoms of great nervous disturbance, seemingly as the result of a direct action of the poison upon the nervous system. Sometimes a tendency to syncope is very marked. The urine is usually lessened or suppressed. Black urine, due to the presence of hæmoglobin without unaltered blood-corpuscles, has been noted; in this case, after death all the tissues were found stained with altered blood, and evidently destruction of the blood was an important factor in the fatal result (*N. Y. Med. Record*, xxi. 567); fatty degeneration of the liver was also found. If the patient survives for twenty-four hours, jaundice nearly always shows itself. After this, profound depression with nervous symptoms may develop and end in death; but not rarely a favorable issue results, in which case the symptoms of gastro-intestinal inflammation with fever develop themselves. In the experiments of Ellenberger and V. Hofmeister upon animals, hæmaturia and fatty degeneration of the liver were prominent phenomena (*Arch. Wissen. Prakt. Thierheilk.*, x. 228). The copper is said to be eliminated more freely with the salivary and intestinal secretions than with the urine (Galippe, *loc. cit.*, p. 41).

As the action of the sulphate of copper is exceedingly rapid, any antidote to be of avail must be given at once and act quickly. Milk and eggs are almost always at hand, and are the most efficient antidotes. No time should be lost in attempting to separate the yolk from the white of the egg, but the egg should be broken into a bowl as quickly as possible, a little water added, and the whole stirred up and exhibited. The dose should be repeated several times, especially when there is vomiting. Soap or a fixed alkali may be given. The yellow *prussiate of potash*, when pure, is harmless, and precipitates instantly an insoluble compound of copper from solutions of its salt. When it is to be had in time, it may therefore be used as an antidote to the sulphate. The treatment of copper-poisoning after the administration of the antidote consists in meeting the indications as they arise; opium

should be used freely. When death occurs, the results of gastro-intestinal inflammation are usually found; sometimes the intestine has a decided bluish tint, and occasionally submucous ecchymoses occur. In exceptional cases, it is said, there are no evidences of inflammation in the alimentary canal.* Fatty degeneration of the liver has been noted (*N. Y. Medical Record*, xxi. 567).

If chronic copper-poisoning ever exist among workers in the metal, it must be very rarely. The chief symptoms are asserted to be "a coppery taste in the mouth, giddiness, pain in the bowels, vomiting, occasional diarrhœa, and wasting of the body." Dr. Clapton (*Med. Times and Gaz.*, June, 1868) has pointed out, as characteristic, a green line upon the gums; this was also observed by Professor Taylor, but its constancy is not assured. Thus, a green line was found on the teeth of all but two or three of a number of workers in the metal examined by a committee of the London Clinical Society (*Transactions*, 1870, p. 13), but there was no line on the gums of any of them. Although Dr. Faulk (*Deutsche Klinik*, ix. 376) asserts that the habitual use of acetate of copper produces progressive paralysis with failure of respiration and death, it seems to me clearly established that small quantities of the metal can be taken into the system without injury. Both Galippe and Drs. Burey and Ducom have found the metal almost without influence upon dogs (*Archives de Physiol. Norm. et Pathol.*, 1877, iv. 183). Galippe (*Comptes-Rendus*, lxxxiv. 718) fed himself for one month on food containing a large amount of copper without causing any symptoms of intoxication. Further, copper is habitually used upon the continent of Europe, especially in France and Belgium, in the preparation of vegetables,—French peas, beans, etc., owing their attractive color to their treatment with copper, which can be chemically recognized in them. The possibility of injury resulting from the use of such food has been repeatedly investigated by French and Belgian commissions, and the general verdict has been that no harm is produced. The fact that twenty millions of cans of these food-articles are consumed every year, and that after thirty-six years' continuance of the custom it has not been established that any harm is done, is sufficient in itself to prove that the vegetables are not poisonous. For an elaborate recent discussion upon the subject, consult *Bull. de l'Acad. Roy. de Méd. de Belge*, vols. xix. and xx., 1885 and 1886.

CUPRI ACETAS.—Copper acetate is in deep-green, prismatic crystals, yielding a bright-green powder; while the impure subacetate, or verdi-

* For a fatal case of repeated poisoning by copper, with much information of value to chemical experts, see *La France Méd.*, September, 1874, abstracted in *Half-Yearly Compendium*, Jan. 1875. Bournavette and Yvon (*Revue Scientifique*, p. 659, 1874) found two hundred and ninety-five milligrammes of metallic copper in the liver of a woman who had taken the ammoniacal sulphate three months previously. Minute quantities of copper exist in the normal human body (*Bull. Théray.*, xxi. 88).

gris, occurs in masses of a pale-green color, which are often composed of minute silky crystals. Both acetates closely resemble the sulphate in physiological, therapeutical, and toxicological properties, but are less active.

ARGENTUM—SILVER.

ARGENTI NITRAS—SILVER NITRATE. U.S.

This is officially prepared by heating together silver, nitric acid, and a small quantity of water. It is a heavy anhydrous salt, crystallizing in translucent, shining, rhombic plates, and having a styptic, exceedingly metallic, corrosive taste. It is soluble, at 59° F., in 0.6 part of water, in twenty-six parts of alcohol, in 0.1 part of boiling water, and in five parts of boiling alcohol. Hydrochloric acid or a soluble chloride throws down from its solution a white curdy precipitate *wholly* soluble in ammonia. For external use the crystals are melted and run into moulds, where they harden into round, grayish, brittle sticks, about the size of a goose-quill, and having a radiated crystalline fracture. These constitute the official *Argenti nitras fusus*. As only the pure salt will make well-formed crystals, the impure products are always manufactured into the preparations just named, which should therefore not be employed internally. When silver nitrate, either in substance or in solution, is exposed to the conjoint influence of light and of even a minute portion of organic matter, it turns black, and is converted into an insoluble substance, which has been believed to be metallic silver, but is more probably an oxide. For this reason the white stains which it first makes when applied to living tissues soon blacken.

PHYSIOLOGICAL ACTION.—Nitrate of silver coagulates albumen, and, when applied in its pure state to living tissues, acts as a caustic, coating them over with a white almost membranous film. The caustic action is, however, not a deep one, because penetration of the salt into the tissues is soon prevented by the thick and tough skin or stratum which is formed. When applied in a dilute solution it acts as an astringent, constricting the vessels and overcoming relaxation. Its local action, however, is not simply that of an astringent, but is certainly peculiar and apparently alterative to nutrition.

When taken internally in sufficient dose, this salt, by virtue of its corrosive action, is a poison, producing gastro-enteritis; but it also acts directly upon the nervous system. Orfila and other of the earlier observers experimented upon it by injecting it directly into the veins of animals. When exhibited in this way, it must, by coagulating the albumen of the blood, produce thrombi, to which the subsequent symptoms are in greater or less measure to be ascribed. This method of experimentation can therefore throw but little light upon the action of nitrate of silver when taken into the stomach.

It is evident that in the stomach the nitrate of silver cannot long maintain its integrity. Dr. Bogolowsky has found (*Virchow's Archiv*,

xlvi. 413) that when the nitrate is added to a peptone it is readily dissolved, and that the solution formed does not coagulate albumen.* That in this or in some other analogous form silver is absorbed is proved by its having been found in various internal organs and by the discoloration which follows its protracted use. When it is exhibited for a long continuous period, the skin often acquires a peculiar bluish slate color, which may become very dark, and in decided cases the conjunctiva and even the mucous membrane of the mouth are involved. The silver is found in all the tissues of the skin below the rete Malpighii† (Frommann, *Virchow's Archiv*, xvii. 135; Riemer, *Archiv d. Heilkunde*, xvi. 296, xvii. 330; Neumann, *Medizin. Jahrbucher*, 1877, 369). Professor E. Harnack asserts (*Arzneimittellehre*, 1883, 410) that in all recorded cases of argyria at least thirty grammes of the salt have been taken. The staining of the skin is always preceded by a dark discoloration of the mucous membrane of the mouth and gums. Both Heller and Orfila failed to detect silver in the urine of animals taking it; but probably it is eliminated, though slowly and in very small quantities, by the kidneys.

By an elaborate series of experiments, M. Chas. Rougot (*Archives de Physiologie*, July, 1873, p. 356) has shown that upon all animals from a crab to a dog the soluble salts of silver act as a poison, causing in mammals vomiting and purging, and in them and the lower animals violent disturbance of the motor functions, as shown by paralysis and convulsions, and of the respiration, ending finally in death by asphyxia. This is in accord with the observations of other investigators. MM. Rabuteau and Mourier have found that the almost instantaneous death which Charcot and Ball first noted as following the injection of a large dose of the nitrate of silver into the veins is due to a direct paralyzing influence of the drug upon the muscle of the heart. M. Rougot has never seen this form of death follow the hypodermic or internal administration of the poison, the heart always continuing to beat for a greater or less length of time after the cessation of respiration, and also retaining its irritability.

As already stated, both convulsions and paralysis are present in acute argyria, or silver-poisoning. The convulsions are severe, generally tetanic, and according to Rougot are plainly reflex. A peculiarity noted by Rougot is the persistence of the convulsions after the complete abolition of voluntary movements. M. Curci affirms that they are due

* For recent studies of this character, see Isidore Neumann (*loc. cit.*), also A. von Fragenslein (*Berlin Klin. Wochens.*, 1877, 204).

† In an elaborate study of the organs of a case of argyria, Riemer found the silver in the glomerules of the kidney, the intima of the aorta, the choroid plexus, and the mesenteric glands. He believes that it is never deposited inside the cells, but in the cellular tissue, and that the silver preparation is reduced in the intestines, and the fine particles of the silver, carried in the blood and lymph. O. Loew (*Pflüger's Archiv*, xxiv. 603) asserts, however, that the silver is deposited inside of the renal endothelium cells, and, as he has found that protoplasm has reducing powers, believes that the silver is reduced in the cells from a solution.

to excitation of the motor tract of the cord, and that this is preceded by a similar influence upon the sensory tracts (*London Med. Record*, 1877, p. 72).

The death is due, in argyria, to cessation of the respiration; Rouget (*loc. cit.*, p. 351) even states that he has witnessed the suspension of the latter function in the frog while the activity of the reflex movements was much beyond normal. In the dog and in the full-grown cat this asphyxia is accompanied by an outpouring of mucus in the lungs, pulmonary congestion and oedema being found on post-mortem examination. Two theories have been propounded as to the cause of the asphyxia: one, that it is simply due to the choking up of the lungs by the congestion and the excessive secretion whose origin is an altered state of the blood; a second, that both the asphyxia and the lesions in the lungs have their origin in a direct action of the poison upon the nerve-centres.

The first view has been especially supported by Krahmer and by Rabuteau and Mourier. Unfortunately, I have not seen the original papers of these physicians; but, according to Rouget, the basis of argument of Krahmer is simply the ecchymoses which he found in horses dead of the poison, while that of Rabuteau and Mourier is the fluidity of the blood after death, and the existence in it of granules which, on account of their solubility in ammonia, were believed to be the chloride of silver. The French observers were, however, almost certainly mistaken in their belief that these granules were chloride of silver, since ammonia dissolves hæmatin as freely as it does the chloride.

In 1864 Charcot and Ball (*Gazette Méd.*, 1864) made a series of experiments in which a silver salt that did not coagulate albumen was injected directly into the blood. They noted not only the respiratory embarrassment but also that the hinder extremities were suddenly paralyzed, and concluded that both the asphyxia and the lung-trouble were due to an affection of the central nervous system. In 1869 Dr. Bogolowsky, of Moscow, studied (*Virchow's Archiv*, 1869, Bd. xlv.) the action of a peptone of the nitrate when used hypodermically. He found, on examination of the blood of a poisoned animal, that the spectrum analysis (*loc. cit.*, p. 415) betrayed nothing abnormal; that the red corpuscles appeared paler and their outline more delicate than normal; that the white corpuscles were natural. On the other hand, Rouget (*loc. cit.*, p. 361) examined microscopically the blood of animals poisoned with the nitrate of silver, and found it perfectly normal. The only conclusion to be drawn from all this seems to me to be that at present there is no proof whatever that the symptoms of acute argyria are due to alterations in the blood. That the embarrassment of respiration is not due to local lesions in the lungs is abundantly shown by the experiments of Rouget, who found that while in all animals these respiratory symptoms are very prominent, in only a few species are decided pulmonic lesions found after death. From all these facts I

think it highly probable, if not altogether certain, that the theory propounded by MM. Charcot and Ball is correct. That the motor disturbance is centric, not peripheral, in its origin, is shown by the fact noted by Rouget (*loc. cit.*, p. 354), that the muscles and nerves preserve their excitability after the arrest of the respiration.

The various facts which have been thus far brought forward in regard to the physiological action of silver, although interesting to the toxicologist, have very little reference to its therapeutic use, since it is never employed to produce an acute constitutional influence.

The action of the drug when exhibited continuously for a length of time in large doses has been investigated by Dr. Bogolowsky upon dogs and rabbits. He found that it produced loss of appetite, wasting, slight lowering of bodily temperature, diarrhoea, diminution of the quantity of urine passed, with increase of its specific gravity and often with the presence of albumen, and transitory paralysis. How far some of these symptoms were due to the direct constitutional action of the poison, and how far to derangement of the digestion dependent upon its local influence, is perhaps an open question. The local action was avoided, however, as much as possible, by the use of an albuminate or of the double phosphate of silver and sodium, which does not coagulate albumen. Comparative examinations of the blood showed that the hæmoglobin was diminished by more than one-third. The blood was also rendered very aplastic, as was betrayed by the constant tendency to the formation of ecchymoses. As some one has suggested that the silver in these cases replaces the iron of the blood-corpuscles, Dr. Bogolowsky made a chemical examination of the latter, but failed to find any traces of silver in them,—no doubt because it was not there. The solid tissues were found, after death from chronic argyria, to be in an advanced stage of degeneration, which especially affected epithelial structures. The first change was swelling and opacity of the cells, with obscuration of the nucleus. After this came fatty degeneration, fatty globules in the cell, destruction of nucleus, and finally of the cell itself. The liver and kidneys were profoundly influenced, as was also the muscular structure, especially of the heart. These results obtained by Bogolowsky have been in the main corroborated by A. V. Rózsahégyi (*Arch. Exper. Path. Pharm.*, ix. 295).

The summary which has been here offered comprises all our knowledge of the physiological action of the preparations of silver. Unfortunately, it does not throw much light upon their therapeutic use. The results of the chronic poisoning are so closely analogous to those produced under similar circumstances by antimony, arsenic, and probably other metallic poisons as to indicate that silver given internally acts upon the nutrition of the body,—in other words, that it is an *alterative*.

THERAPEUTICS.—By far the most frequent employment of nitrate of silver in therapeutics is for its local action, either upon the surface of the body or upon those mucous membranes that can be reached directly by the drug.

As a simple *caustic*, the salt may be used whenever only a superficial action is required: for reasons already given (page 464), it is useless whenever it is necessary to produce a deep eschar. As a *caustic* and an *alterative*, it is applied in solid form to many *ulcerated surfaces*, for the purpose of destroying superficial diseased tissue and of substituting, when the eschar separates, a healthy for an unhealthy action. As an *antiphlogistic*, nitrate of silver acts not only as an astringent, but also in some way not clearly understood. In the various inflammations of the mucous membranes, such as *conjunctivitis*, *faucitis*, *laryngitis*, *urethritis*, etc., it is used very frequently, not only in the stage of relaxation, but also in the beginning of the attack. In *conjunctivitis*, the solution employed should not, under ordinary circumstances, be stronger than one or two grains to the ounce; and it should not be used at all if any corneal ulceration exists, since a deposit of silver is liable to occur and to produce opacity. In *faucitis*, the strength of the solution may vary from thirty to sixty grains to the fluidounce. Even a saturated solution can scarcely be looked upon as caustic to the more robust mucous membranes. In ordinary cases of *sore throat*, the application once a day or every alternate day is generally sufficient. It is best made by means of a good-sized camel's-hair brush, each part of the inflamed surface being distinctly touched, and not the whole simply daubed or slopped over by means of a very large brush or a sponge probang, as is often done. In severe cases it may be necessary to use the solution twice a day. Dr. Carl Seiler states that while solutions of nitrate of silver of less than sixty grains to the ounce cause pain when applied to the throat, solutions of one hundred and twenty to two hundred and fifty grains act as local anæsthetics, relieving soreness, and usually arresting acute inflammations at once, if applied in the first twenty-four hours, before inflammatory exudation has occurred (*Journ. Amer. Med. Assoc.*, i. 266). In *laryngitis*, the solution may contain from ten to twenty grains to the ounce, and should be applied with a brush by the aid of the laryngoscopic mirror. An attack of *urethritis* may sometimes be aborted in its forming stage by the injection of a strong solution (grs. xii to f3i) of the salt; but the practice is of doubtful expediency, since when it fails it greatly aggravates the trouble. In the *advanced stages of gonorrhœa*, weak injections (grs. i or ii to f3i) are often very serviceable.

Many years ago (1828) Mr. John Higginbottom originated the practice of treating *erysipelas* by the nitrate of silver, and his plan has received a great deal of commendation from authorities, but certainly has not been generally adopted by the profession. One or two cases of bad results, from ulceration of the skin apparently due to the local application, have deterred me from giving the method a fair trial, and I do not feel able to offer any opinion upon the practice. Mr. Higginbottom has more recently (*Pract.*, 1869, ii. 34) reconfirmed the value of the

treatment, stating that its want of general adoption is due to its being so often imperfectly carried out, and gives the following directions:

"The affected part should be well washed with soap and water, then with water alone to remove every particle of soap, then to be wiped dry with a soft towel. The concentrated solution of four scruples of the nitrate of silver to four drachms of distilled water is then to be applied two or three times on the inflamed surface, and beyond it on the healthy skin to the extent of two or three inches. The solution may be applied with a small piece of clean linen attached to the end of a short stick, the linen to be renewed at every subsequent application. As the solution of the nitrate of silver is colorless, it is necessary to pass a little linen, just moistened, over every part where it has been used, in order to be equally diffused, so that no part may be left untouched. In about twelve hours it will be seen whether the solution has been well applied. If any inflamed part be unaffected, the solution must be immediately reapplied. Sometimes, even after the most decided application of the nitrate of silver, the inflammation may spread; but it is then generally much less severe, and is eventually checked by repeated applications. It is desirable to visit the patient every twelve hours until the inflammation is subdued."

In *superficial inflammations* other than erysipelatous I have frequently used nitrate of silver in this way, often with great advantage. Freely applied to the skin of the whole finger, it will sometimes even abort a commencing felon, or, applied to the scrotum, an *epididymitis*.

Internally, nitrate of silver is exceedingly useful in stomachic and to a less extent in enteric diseases, exerting no doubt a purely local influence. In that form of *dyspepsia* characterized by the vomiting of large quantities of yeasty fluid, it has yielded in my hands better results than any other remedy; and the same may be said of *chronic gastritis* and of *gastric ulcer*. The rules of administration are identical in these three diseases. In the first place, regulation of the diet is imperative: if the case be a bad one, all eating of meals should be suspended, and the patient receive every two or three hours a cup of sweet milk, with sound toasted bread broken up and thoroughly softened in it. Nitrate of silver should be administered in pill form, one-quarter to one-half grain three or four times a day, taken when the stomach is empty. In very serious cases, when all food is rejected by the stomach, it is sometimes advisable to allow absolute rest for two or three days to that viscus, the patient being fed by the rectum, and only a little water and pills of silver with opium being taken by the mouth. Under these circumstances, the return to the usual method of taking food must be very gradual, at first only a tablespoonful each of milk and of lime-water being administered every hour. In *chronic enteritis* or *colitis*, nitrate of silver is sometimes of service, especially if there be ulceration.

For its constitutional effects nitrate of silver is used solely in diseases of the nervous system. It was formerly given in *epilepsy*; but it has

passed out of use. There is one serious objection to the employment of the salt,—namely, the discoloration of the skin which sometimes follows its continuous use. Again, it is not understood in what class of cases the drug is of especial value, and there is no means of judging as to its applicability to any individual case. When other means have failed, however, the nitrate of silver may be tried in epilepsy, the patient or his friends being informed that although with proper precautions the chances of discoloration are very few, yet it may occur.

In *chronic inflammations* of the spinal cord, whether affecting chiefly the posterior columns and constituting *locomotor ataxia*, or the anterior and giving rise to *paraplegia*, the nitrate of silver is one of the few remedies that are ever of any service: although it most frequently fails, yet it occasionally does good, and in some cases has apparently even permanently arrested the disease.

TOXICOLOGY.—The symptoms produced by the ingestion of large doses of nitrate of silver are partly gastro-intestinal and partly cerebro-spinal. In some instances the one series of phenomena predominate; in others, those of the other class. In a case at the Hôpital St.-Louis in 1839 (*Beck's Medical Jurisprudence*, i. 675, Phila., 1863) the symptoms were insensibility, violent convulsions, and dilated pupils, with, on a partial return to consciousness, intense gastric pain; complete restoration of consciousness did not occur until eleven hours after admission, and the coma returned at intervals during several days.

Vertigo, coma, convulsions, great muscular weakness, paralysis, with intense disturbance of respiration, are in these cases the manifestations of disturbed innervation; whilst the abdominal symptoms are those of gastro-enteritis. The diagnosis can generally be made by the discolorations of the lips and skin,—at first white, afterwards black,—and by the blackish or brownish vomit; when the customary antidote has been given, both vomit and stools are generally white and curdy. At post-mortem the stomach and bowels are found corroded, often ecchymosed and with patches of a white or grayish color. Poisoning by nitrate of silver is not common, and I know of but three fatal cases,—one in 1837 (Taylor, *Medical Jurisprudence*, 2d ed., vol. i. p. 319), one in 1861, a woman killed by fifty grains in solution in divided doses, and one in 1871, a child destroyed by a piece of the solid stick three-quarters of an inch long, in spite of the use of the antidote (*Scattergood, Brit. Med. Journ.*, May, 1871).

The treatment consists in the administration at once of large amounts of *common salt*,—the chemical antidote,—the constant use of large draughts of milk, and the meeting of symptoms as they arise.

The fatal dose of silver varies very much, according, no doubt, to the presence of substances capable of decomposing it in the stomach. Thirty grains have killed; and recovery has taken place after the ingestion of an ounce (case, Husemann, *Toxicologie*, Berlin, 1862, p. 868).

Chronic *argyria*, or discoloration of the skin by silver, is usually unaccompanied by disturbances of health, although in severe cases the discoloration affects not only the skin, lips, gums, and sclerotic, but even the internal organs, such as the liver, spleen, and kidneys. It is therefore not due, as has been thought, to the chloride of silver, since the latter becomes dark only under the influence of the light, but to a deposition of silver itself or of its oxide.* Dr. S. Kryszinski (*Lond. Med. Rec.*, August 16, 1886) found the granules in almost every tissue of the body, and states that they are an organic compound of silver, the exact nature of which has not yet been determined. The minute quantity of the metal present is shown by the analysis of Versmanns (*Virchow's Archiv*, xvii., 1859), who in 14.1 grammes of dried liver found only 0.0068 gramme of metallic silver (0.047 per cent.), and in 8.6 grammes of dried kidney 0.053 gramme (0.061 per cent.). Greater or less success has been claimed for various treatments in *argyria*, but in general they are equally futile. Rogers states that blistering will lighten the color very much, and Eichmann asserts (Husemann, *Toxicologie*, 871) that he has cured two cases by the use of potash baths and of soap baths, each four times a week. The older authorities commend the use of iodide of potassium internally. Dr. L. P. Yandell has reported (*American Practitioner*, June, 1872) two cases in which large doses of the iodide were given for many months for syphilis, and the mercurial vapor-baths used at the same time for the same purpose, with the result of a complete cure of the *argyria*. The fading was gradual.

ADMINISTRATION.—The nitrate of silver should always be given in pill, and, when it is desired to obtain its constitutional influence, after meals, during the process of digestion; but when its local action on the alimentary canal is required, it should be administered one or two hours before meals; and if the bowels are to be reached, the pill should have been made some time and be heavily coated, so as to be dissolved as slowly as possible. When it is given in epilepsy or other chronic disease, its administration should be suspended for one week at the end of every third week, and its employment should not extend over a longer time than three months without a protracted intermission.

Argenti Nitras Dilutus, U.S., is a grayish, solid substance, often in crayons, composed of two parts of potassium nitrate with one part of silver nitrate. It may be used as a very mild caustic.

Silver oxide (*ARGENTI OXIDUM*, U.S.) is an olive-brown powder, very slightly soluble in water, which may be prepared by precipitating the silver nitrate with solution of potassa. It has been introduced into medicine as a substitute for the nitrate, with the idea that it would

* According to Rússahégai, Hermann has seen one case in which preceding the deposition of the silver there were malaise, emaciation, failure of memory, ringing in the ears, deafness, and spasms of the ocular muscles.

accomplish in diseases of the nervous system all that that drug is capable of, and at the same time not discolor the skin. With our present knowledge of the method of absorption of the nitrate, this seems highly improbable, and it is contradicted by experience. (Case, *Phila. Med. Times*, vi. 204.) Silver oxide is not caustic when locally applied, but probably exerts some astringent action, and it has been commended in *pyrosis*. In nervous affections it is probably of equal value with the nitrate. The dose is a grain, in pill, three or four times a day.

Silver cyanide (ARGENTI CYANIDUM, U.S.) is used solely for the preparation of hydrocyanic acid. *Silver iodide* (ARGENTI IODIDUM, U.S.) has been used as an alterative, but is of very doubtful value.

FAMILY II.—TONICS.

MINERAL TONICS.

FERRUM—IRON. U.S.

SINCE iron constitutes a necessary integrant portion of the red blood-corpuscles, it is a food rather than a medicine. A very large proportion of the various articles of ordinary diet contain a trace of it, and it must undoubtedly find entrance with the food into the blood. Although a very large amount of work has been done by chemists upon the absorption and elimination of iron, the results have been so imperfect, contradictory, and difficult of explanation that they are at present of very little use to the clinician. Iron is probably at all times in the urine in minute quantities. Among the older chemists, Quevenne taught that the exhibition of the salts of iron had very little influence upon the amount of iron in the urine, whilst Becquerel found that the increased elimination of iron commenced directly after the first taking of a ferruginous preparation, and, though varying notably from day to day, continued on the whole until the end. Among the later chemists, Professor Bunge, of Basel, believes that no salts of iron are absorbed into the blood, and that the value of the iron in chlorosis is due to its local action on the gastric juices. His theory is that in chlorosis there is a great poverty of gastric juice, with an excessive formation of alkaline sulphides; that these alkaline sulphides decompose the absorbable albuminous iron compounds of the food, and render them, like ordinary salts, incapable of absorption; that the ordinary iron preparations occupy the alkaline sulphides, and allow the albuminous iron compounds to be absorbed. He bases this belief upon the experimental results obtained by himself and by Hamburger (*Zeitschr. f. Physiolog. Chem.*, 1879, ii.), which he believes prove, first, that in the healthy subject continued administration of iron does not raise the red blood-corpuscles or hæmoglobin; second, that when iron is given it does not increase the amount excreted in the urine. (See also *Journ. of Comp. Path. and Therap.*, December, 1888.)

Nicolai Damaskin, Johann Kumberg, Chr. Busch, and Eugen Stender, working with and under the immediate supervision of Professor Robert, of Dorpat, found, first, that the presence of iron can be

demonstrated in normal filtered or unfiltered urine, both quantitatively and qualitatively; that the elimination of iron does not cease, as has been affirmed, during fasting in man; and that the administration of an official preparation of iron does not cause iron to disappear from the urine: *second*, that the iron exists in the urine in two portions, one in the morphological elements, normal and pathological, of the urine, the other dissolved in the urine itself; it being doubtful whether the iron is or is not simply in the coloring-matter of the urine, but it being certain that this iron in solution is in some very permanent combination, as it resists even heating of the urine with muriatic and nitric acids: * *third*, that the normal relation of the iron in the morphological elements to that in solution appears to be from one to seven to one to eight: *fourth*, that the daily elimination of iron in the urine is scarcely one milligramme, but is subject to much variation, according to nourishment, etc.; in sickness attended with destruction of the blood, or with increase of the morphological elements of the urine, the elimination of the iron increases, but the presence of billiary coloring-matter in the urine has no influence upon it: *fifth*, that when iron and sodium citrate is injected subcutaneously into man, in the dose of one milligramme per seven kilogrammes of weight, forty per cent. of the iron escapes in the urine unaltered, such injections being, however, attended with distinct danger of renal irritation, so that hypodermic injections of iron should only be given in very minute doses: *sixth*, that the administration of the ferrous citrate or of the saccharated iron carbonate by the mouth, in doses of one hundred milligrammes a day, or the rubbing into the skin of the same preparations, does not perceptibly alter the elimination of iron; so that positive proof is still wanting that this and similar preparations of the Pharmacopœia are taken up by the human organism, although Kunkel reached opposite results upon animals, and although these preparations have been proved to have distinct chalybeate influence. In Busch's experiments it was found that either pure or impure hæmoglobin, given internally, moderately increased the elimination of iron from the urine.

The correctness of the theory of Professor Bunge is made doubtful by the research of Dr. Carl Th. Moerner (*Schmidt's Jahrb.*, Bd. cccxxix. p. 227), who finds as the result of the study of urinary indican, etc., during the administration of iron, no reason for believing that the salts of iron act as intestinal antiseptics. Moreover, it seems probable that the iron escapes even more freely through the intestinal tract than it does through the kidney. Thus, Dr. Gottlieb, feeding dogs on food practically free from iron, was able to obtain from the feces nearly ninety-seven per cent. of iron which had been subcutaneously injected. He also found that twenty to sixty-five per cent. of the injected iron

* As it has been shown by Bunge and by Socin that the hæmatogen of the yolk of eggs yields its iron readily to absorption, eggs should be an excellent article of food in anæmia.

could be found in the liver. This latter conclusion strongly concords with results reached by Dr. Carl Jacobi (*Arch. f. Exper. Path.*, xxviii. 3), who, finding that after the injection of iron into the blood of the dog renal elimination ceased in from two to three hours, was led to look for the lost metal, with the result of discovering that two or three hours after the injection fifty per cent. of the injected iron could be found in the liver. This is in accord with Dr. Zaleski (*Arch. f. Exper. Path. u. Pharm.*, xxiii.), who believes that his researches have shown that iron is especially eliminated by the liver.

Peter Robert Berry (*Schmidt's Jahrb.*, Bd. ccxxxvi.) has attempted to study the question of the absorption of iron by looking for it in the intestinal walls microscopically, with absolutely negative results,—results which may be explained either by the supposition that the absorption is so slow that microscopic methods will not detect the iron, or that the iron is absorbed in some form that protects it from the ordinary reagents. Again, as the result of a very elaborate research, Socin (*Zeitsch. f. Physiol. Chemie*, 1890–91) comes to the conclusion that it is impossible to determine the question of iron absorption by simple comparison of the amounts of iron injected and thrown out.

The chemical results which have been epitomized, especially those of Kobert's assistants and of Professor Bunge, would seem to indicate that the inorganic salts of iron are not absorbed, and that the organic products of iron are much more useful than the inorganic; but it must be remembered that the iron may have escaped the observation of these chemists because it was eliminated, not through the kidneys, but through the intestinal tract, and, further, that the pharmacological chemists, in attacking the iron problem, have so far scarcely touched the core of the matter. The real point that the clinician wants to know is, not how much iron is absorbed and runs through the body, but how much is taken into the blood and appropriated by the blood-making organs. It is possible that a preparation, A, should be absorbed, refused by the blood, and pass out by the kidneys, whilst preparation B should be absorbed less readily than was A, and should altogether fail to appear in the urine because that which had been absorbed had been appropriated by the blood. Under such circumstances the second preparation would be much the more valuable, and yet such chemical researches as those of Kobert and Bunge would indicate that it was a preparation of no value.

It seems to me that clinical experience has proved beyond all cavil that most, if not all, of the official iron preparations are absorbed to some extent, and that in the present imperfection of chemical knowledge in this matter the practical doctor should be guided by clinical experience entirely independent of scientific research.

That condition in the blood which is known as anæmia, in which there is either an absolute loss in the number of red blood-corpuscles or a loss in the percentage of hæmoglobin, may arise from direct loss,

as by hemorrhage; by direct destruction of the red blood-corpuscles, as in many forms of poisoning; by failure of supply of food, as in starvation; by failure of primary assimilation, and also by failure in those organs which make blood. When there is need of more supply of material for the manufacture of blood-corpuscles, the immediate usefulness of iron is very explicable; but in most cases of serious anæmia, as met with in disease, there seems to be no such need of ferruginous food; and it is a very important question, which at present, however, we cannot answer with any degree of positiveness, whether medicinal iron has or has not any stimulant influence upon those organs which produce the red blood corpuscles. It is evident, indeed, that we cannot have such knowledge until we have final information as to the methods in which the red blood-corpuscles are evolved. Leaving out of sight those cases which may be spoken of as instances of "accidental anæmia,"—i.e., anæmia due to hemorrhage, poison, starvation, or other temporary cause, which has passed off or is removable, and in which iron may be given as an aid to the rebuilding of the blood,—we find practically the anæmias are divided into two sets: those in which there is a pronounced lessening in the percentage of hæmoglobin in the blood but not a corresponding lessening in the number of red blood-corpuscles, and those in which the red blood-corpuscles are greatly diminished in number. The first class of cases is typified in chlorosis, the second in the essential anæmias.

Of the value of iron in chlorosis there can be no doubt. Thus, Professor Simon (*Animal Chemistry*, London, 1845, Syd. Soc. ed.) reports a case of chlorosis in which, under the steady use of iron for sixty-four days, the globulin increased from 30.86 parts to 90.80 parts per thousand, and the hæmoglobin from 1.431 parts to 4.598 parts per thousand; and Cutler and Bradford (*Amer. Journ. Med. Sci.*, 1878, p. 78) have obtained confirmatory results with Malassez's tubes. In most cases of chronic anæmia with great lessening in the number of red blood-corpuscles, typified by leucæmia and pernicious anæmia, iron is of no service whatever. Unfortunately, the line between the two sets of cases of anæmia is in nature not so sharp as it can be made in treatises, and I have seen cases presenting a chlorotic form of anæmia, in which the anæmia failed to be affected at all by iron or any other treatment, remaining almost as persistent and unconquerable as the blood lesion of leucocythæmia.

The question whether iron acts as a stimulant to the blood-making organs or not is closely connected with the question as to the effect of iron upon healthy individuals. It was formerly believed that the proper administration of the metal to healthy man would produce an excess of the red blood-corpuscles, but more recent investigations, whilst somewhat discordant and not conclusive, have unsettled this belief. The experiments of Nasse (*Lond. Med. Record*, 1877, p. 498) upon dogs are in favor of the older view, while those of E. C. Cutler and E. H. Brad-

ford are in opposition to it.* The first observer, giving iron with fat, noted not only an increase of bodily weight, but also that the specific gravity of the blood rose from 1052 to 1060.8, and the amount of the metal in the blood from 0.477 to 0.755 per thousand parts, both the result of increase in the corpuscular element. Cutler and Bradford experimented upon man, using the tubes of M. Malassez, the result being slight diminution of the red blood-disks. As, however, the experiments were only two in number, and the subjects not under complete control as to conditions of life, these observations can hardly be considered conclusive.

It appears to be a well-established fact that one of the functions of the red blood-corpuscles is to convert oxygen into ozone, which is the efficient form of the element in the system (see paper by A. Sasse, *Vierteljahresschrift für Prakt. Heilkunde*, 1866, Band ii.). The oxide of iron outside of the body certainly possesses an ozonizing power similar to that of the red disk. Thus, a spot of iron mould, i.e., iron oxide, on linen will in time destroy the fabric. The reason of this is the corroding action of the ozone which is slowly generated by the oxide of iron. From a similar cause a fleck of rust on a bright surface of steel will steadily enlarge and deepen. It would seem *a priori* probable that in the blood iron acts as it does out of the body. If this be so, by increasing oxidation an increase of the iron in the blood should cause elevation of temperature and increased elimination of urea. The studies of W. Pokrowsky (*Virchow's Archiv*, Bd. xxii.) have shown that, in cases of anæmia, after the exhibition of iron the temperature does rise, even when in the beginning it was not below normal, and that simultaneously there is an increase in the daily elimination of urea; and the experiments of Botkin, as quoted by Sasse (I have not seen the original), establish the same fact in regard to healthy men. The increased oxidation cannot be due simply to an increase in the number of the red corpuscles, for while the latter accrues slowly, Pokrowsky found that the temperature sometimes rose within five hours after the exhibition of the first dose. It would seem, therefore, that iron acts directly on the blood as an ozonizing agent.

Almost all the preparations of iron are more or less astringent, and when in the blood very probably exert a direct influence upon the tissues, contracting them not merely by increasing their tone, but also by acting on their vital contractility.

The preparations of iron may be divided into those which are soluble and those which are insoluble in water. At first sight it would appear

* Drs. V. H. Meyers and F. Williams (*Arch. f. Exper. Path. u. Pharm.*, xlii. 76) have studied the effects of enormous doses of the tartrate of iron and sodium upon the lower animals. Both frogs and mammals are killed by it,—the symptoms in warm-blooded animals being vomiting, purging, great fall of the blood-pressure, muscular weakness, and finally coma and death. The experiments show that the heart is not much affected, but the vaso-motor system and the spinal motor centres are paralyzed.

that the former class of preparations would be those most readily absorbed. The experiments of Querverne (*loc. cit.*) have, however, demonstrated that these soluble preparations are largely precipitated by the gastric juice even when it is strongly acid. This precipitate is probably an albuminate, mixed, when the gastric juice is alkaline, with the oxide of the metal. It has been further demonstrated by Querverne that these precipitates do not yield so large a percentage of material to the acid gastric juice as do some of the insoluble salts, and the question of its solubility in water seems to be of minor importance in the choice of a chalybeate. Querverne asserts that the reduced iron yields the largest percentage, and, as it is nearly free from astringency, it is one of the best of the chalybeates for use in pill form: but little, if any, inferior is the saccharated carbonate. If a soluble preparation be desired, the ammoniac or potassic tartrates are very unirritating. Mitscherlich believed that the protosalts are more readily absorbed than the sesquisalts, and consequently should be preferred as a general rule. When freely given, almost all preparations of iron form in the intestines sulphides, which blacken the feces.

There are some persons in whom iron produces headache: this can, in some cases, be obviated by the use of laxatives. The observations of M. Petit, Dr. N. A. Bubnow, etc. (*Zeitschr. f. Physiolog. Chem.*, vii.), that the iron preparations in large doses inhibit the digestive processes, throw some light upon these cases. My own experience is that gouty or rheumatic patients bear iron badly, and that sometimes its exhibition seems to greatly aggravate the arthritic symptoms.

THERAPEUTICS.—The chief indication for the use of iron is the existence of *anæmia*; the contra-indication, a state of *plethora*: on these points sufficient has already been said, and the peculiar actions of certain salts will be considered under their respective preparations.

FERRUM REDUCTUM—REDUCED IRON, U.S.—This preparation is also known by the names of *Ferri Pulvis*, *Iron by Hydrogen*, and *Querverne's Iron*. It is made from ferric oxyhydrate by exposing it at a white heat to the action of hydrogen, which takes away the oxygen and leaves the pure metallic iron. It occurs as a light, iron-gray, tasteless powder, which should be completely dissolved by dilute sulphuric acid without yielding the odor of sulphuretted hydrogen, and when touched with a lighted taper should ignite and burn to the brown oxide of iron. If it be black, or if it fail to answer the tests given above, it is impure; and indeed, as offered in the shops, not rarely it is entirely spurious. Of all the efficient preparations of iron it is the freest from astringency. The dose is from two to five grains, taken in pill form after meals. As it is entirely tasteless, it is frequently given to children in chocolate-drops or lozenges.

FERRI OXIDUM HYDRATUM—FERRIC HYDRATE, U.S.—The *Hydrated Oxide of Iron*, made by precipitating ferric sulphate with ammonia, is

a reddish-brown powder, which is used solely as an antidote to arsenic. For this purpose it should be freshly prepared, and should be so moist as to constitute a magma. Its virtues are deteriorated by age, even when it is kept under water, and are entirely destroyed by drying. If the solution of the ferric sulphate be not at hand in an emergency, the chloride will yield just as useful a product, and sodium carbonate may be substituted, if circumstances necessitate it, for the ammonia. The precipitate falls at once, and may be washed by putting it in a piece of muslin, squeezing out the original fluid, and then pouring on some fresh water. As the ferric hydrate is perfectly innocuous, it should be very freely administered when used as an antidote, especially since it acts only when in excess. A teaspoonful to a tablespoonful of it should be stirred up in water and taken at once, the dose being repeated several times if necessary. The *Ferri Oxidum Hydratum cum Magnesia*, U.S., differs from the ferric hydrate in containing magnesia, which is substituted in excess for the ammonia as a precipitant. As magnesia is not at all irritant, and is itself antidotal to arsenic, this new preparation offers decided advantages over the older antidote. It should be given freely.

FERRI CARBONAS SACCHARATUS—SACCHARATED FERROUS CARBONATE, U.S.—This greenish-gray powder is made by precipitating a solution of the ferrous sulphate by sodium bicarbonate and adding sugar in sufficient quantities. During drying, sugar is kept constantly present in large amount, so as to prevent the absorption of oxygen, and the consequent conversion of the ferrous carbonate into the ferric oxide. This is a very good chalybeate, nearly free from astringency, and may be given in doses of from three to five grains, in pill form. *Griffith's Mixture* (*Mistura Ferri Composita*, U.S.) contains the ferrous carbonate and myrrh, and has been much used in *anæmia* with *amenorrhæa* in doses of from one to two tablespoonfuls.

FERRI SULPHAS—FERROUS SULPHATE, U.S. ($\text{FeO}, \text{SO}_3 + 7\text{H}_2\text{O} = \text{FeSO}_4 + 7\text{H}_2\text{O}$).—The pure ferrous sulphate is made by dissolving iron in dilute sulphuric acid. It occurs in transparent, efflorescent, rhombic prisms of a pale bluish-green color and a metallic styptic taste. The ferrous sulphate is a very decided astringent, and in a concentrated form and sufficient amount acts as an irritant poison, producing vomiting, purging, and gastro-intestinal inflammation.* Externally its solution (five to twenty-five grains to the fluidounce) is used as an astringent lotion. It has been especially recommended in this form (3i to Oj) in *erysipelas*. As a simple chalybeate the ferrous sulphate should never be used. In *chronic diarrhæa* it is sometimes employed as a tonic astringent.

* In a case reported in the *N. Y. Med. Journ.*, xxxviii. 401, the early symptoms, as stated by the patient, were chiefly nervous: little confidence can, however, be reposed in the patient's report of symptoms or of the amount ingested.

gent. Dose, three grains; in the form of the dried sulphate (*Ferri Sulphas Exsiccatus*, U.S.), one grain.

LIQUOR FERRI SUBSULPHATIS—SOLUTION OF FERRIC SUBSULPHATE, U.S.—MONSEL'S SOLUTION.—The solution of the subsulphate [of the sesquioxide] of iron (often incorrectly called solution of the persulphate of iron) is a most powerful astringent and styptic, and is used solely as such. It is but slightly irritant, and is the best of all the astringents for stanching hemorrhage when it can be applied directly to the part, as in external wounds, or in *hæmatemesis*. In hemorrhage from the stomach, ten drops of it may be given in a tablespoonful of water, the dose being repeated as necessary. Applied by means of the atomizer, it is often very efficient in *hæmoptysis*. In such a case the fluid to be atomized should have the strength of from five to twenty drops to the ounce. The inhalation should last from five to fifteen minutes, and be repeated at intervals of an hour or longer. It is very essential that the liquid should be finely pulverized. In *diphtheria*, Monsel's solution is very valuable applied freely, of full strength or diluted *pro re nata*, to the throat every three to twelve hours. In overdose, Monsel's solution is an irritant poison: the antidote is soap or an alkaline carbonate.

The *Solution of Ferric Sulphate* (*LIQUOR FERRI TERSULPHATIS*, U.S.), owing to its irritant action, is used only to make the ferric preparations.

TINCTURA FERRI CHLORIDI.—TINCTURE OF FERRIC CHLORIDE, 25 per cent., U.S., contains the ferric chloride, hydrochloric acid, and alcohol, and, from the reactions of the last two ingredients, hydrochloric ether. It is prepared by adding alcohol to the official *Liquor Ferri Chloridi*, and is a reddish-yellow, astringent, irritating, somewhat corrosive liquid. It is an excellent chalybeate, possessed of peculiar properties, probably in some measure due to the ether which it contains. It is a diuretic, increasing often very decidedly the daily urinary secretion. It appears also to exert an astringent influence upon the urinogenital mucous membrane, and is frequently employed with tincture of cantharides in *gleet*. In *chronic Bright's disease* it is often of very great service as a chalybeate diuretic. In *erysipelas* it is constantly employed with remarkable results, controlling the disease in a manner not yet understood. Analogy has suggested its employment in other adynamic affections, such as *diphtheria* and *pyæmia*, but its value in these diseases is much more doubtful. Locally it is used as an astringent in *sore throat*; for this purpose its strength should be reduced at least one-half. As it is very destructive to the teeth, care ought to be exercised in its use about the mouth, and also in its administration. The dose is from fifteen to thirty drops, given as a chalybeate three times a day; in *erysipelas*, every two or three hours. The orange-yellow, crystalline, deliquescent *Ferric Chloride* (*FERRI CHLORIDUM*) (Fe_2Cl_3 — Fe_3Cl_2) is official, but is very rarely used.

SYRUPUS FERRI IODIDI, U.S.—The *Syrup of Ferrous Iodide* is a transparent, greenish liquid, of a sweet, ferruginous taste. It deposits no sediment on keeping, and should not affect the color of starch. If it strikes a blue color with the latter substance, it contains free iodine. The syrup of ferrous iodide is a favorite remedy in those cases of anemia in which there is a distinct scrofulous taint. It is believed to possess the peculiar alterative powers of iodine, conjoined with the tonic properties of iron. It is much used in *scrofulosis* occurring in anæmic children; but it certainly possesses no advantages over a ferruginous tonic and iodine when given separately but simultaneously. Indeed, it seems to me uncertain whether its use is as effective as the separate administration of iodine and iron. The dose of it for a child two years old is five to ten drops; for an adult, thirty to forty minims. As it affects the teeth very seriously, it should always be freely diluted when taken, and the mouth should be well washed after its administration.

FERRI IODIDUM SACCHARATUM, U.S.—*Saccharated Ferrous Iodide* is a yellowish-white or grayish powder which represents the chemical and medical properties of the corresponding syrup, being prepared by a parallel process. It may be substituted for the syrup in doses of from two to five grains given in pill form.

DIALYZED IRON.—*Ferrum Dialysatum.*—This is a clear, neutral, nearly tasteless, dark-red liquid, prepared by dialyzing a solution of the chloride of iron. Its exact chemical composition is uncertain. It contains a minute proportion of chloride, and it is possible that the iron exists as a basic oxychloride. It bears dilution with pure water, but is at once precipitated by alkalis, almost all soluble salts, and many organic substances. As the iron oxide in this condition is unable to pass through animal membranes, it has been asserted that it cannot be absorbed. Clinical experience shows, however, that it is absorbed, and *a priori* it seems certain that the dialyzed iron must undergo change the moment it enters the stomach. In what form absorption takes place we do not know. Its tastelessness, harmlessness to the teeth, and comparative freedom from astringency have rendered it a favorite chalybeate, notwithstanding its feebleness. The assertion frequently made that it never constipates is an error. It should never be used in combination. The dose is twenty to forty drops. Dialyzed iron is antidotal to arsenic. It is harmless, and in cases of poisoning a tablespoonful should be administered at once, and repeated *pro re nata* (see *Phila. Med. Times*, vol. viii. pp. 104, 151, 335).

There are five official *Iron Citrates*, all soluble in water.* Two of

* Dr. Glaescke (*Arch. f. Exper. Path. u. Pharm.*, xvii. 466) has experimented upon rabbits by the hypodermic injection of citrate of iron. He finds that the iron appears in the urine in half an hour, that the maximum proportion is reached in two to four hours, and that

these (FERRI CITRAS and FERRI ET AMMONII CITRAS) occur in garnet-colored scales, and are simply mild chalybeates. Dose, five grains. The *Iron and Quinine Citrate* (FERRI ET QUININÆ CITRAS), in transparent scales, varying from reddish brown to yellowish brown in color, and *Soluble Iron and Quinine Citrate* (FERRI ET QUININÆ CITRAS SOLUBILIS, U.S.), each containing twelve per cent. of alkaloid, may be given in doses of five grains or more. The *Iron and Strychnine Citrate* (FERRI ET STRYCHNINÆ CITRAS) contains one per cent. of strychnine.*

There are two official *Iron Tartrates* (FERRI ET AMMONII TARTRAS and FERRI ET POTASSII TARTRAS), each occurring in garnet scales, and each soluble in water. Dose, five grains. The *Ferrous Lactate* (FERRI LACTAS, U.S.) occurs in greenish-white crystalline crusts or grains, soluble in forty parts of water. It is a good chalybeate. Dose, five grains. *Soluble Ferric Phosphate* (FERRI PHOSPHAS SOLUBILIS) and *Soluble Ferric Pyrophosphate* (FERRI PYROPHOSPHAS SOLUBILIS) are excellent preparations, occurring in apple-green scales, completely soluble in water, and nearly free from astringency and ferruginous taste. Dose, five grains. *Ferric Ammonium Sulphate* (FERRI ET AMMONII SULPHAS, U.S.) occurs in octahedral crystals of a pale violet color: it is freely soluble in water, is very astringent, and is used only in atonic leucorrhœa, in which affection marked benefit is often gained by the exhibition of it in five-grain doses three times a day. *Bromide of Iron* (not official) has recently been highly recommended by Dr. Da Costa in chorea and incontinence of urine in children (*Medical and Surgical Reporter*, 1874). He gives, to a child, five grains, dissolved in syrup, and rapidly increases the dose to twenty grains. In a few trials I have found it useless in chorea.

MANGANESE.—The *Manganese Dioxide* (MANGANI DIOXIDUM, U.S.) and the *Manganese Sulphate* (MANGANI SULPHAS, U.S.) have been supposed by some to possess therapeutic properties similar to those of iron. The metal manganese certainly exists in the blood, but its salts have failed to gain the confidence of the profession, although highly recommended by Harmon, of Belgium, and by Pétrequin (*Nouvelles Recherches du Manganèse*, 2d ed., Paris, 1852, also *Bull. Thérap.*, March, 1852) as an adjuvant to the chalybeates. In Dr. Garrod's experiments upon anemia (*Med. Times and Gaz.*, 1863) the preparations of manganese failed to be of service. C. C. Gmelin is said (*U.S. Dispensatory*) to have found the sulphate act as a powerful cholagogue on the lower animals, and Dr. Thomson states that it is a purgative to man in doses of one or two drachms. Dr. Leand affirms (*Glasgow Med. Journ.*, Jan.

after twenty-five hours elimination ceases. In man he states that these injections are well borne and the therapeutic effects satisfactory. The dose of the citrate used for an adult was about 1.5 grains.

* The alkaloidal compounds with iron are very inelligible preparations, because they do not allow the practitioner to vary the proportionate doses of the two ingredients.

1865) that the manganese oxide is therapeutically equivalent to the preparations of bismuth excepting in that it does not constipate, and that it may be used with advantage in *gastralgia*, *pyrosis*, and similar stomachic derangements.

ACIDUM SULPHURICUM—SULPHURIC ACID. U.S.

Oil of Vitriol (H_2SO_4) is, when pure, a colorless, heavy liquid (sp. gr. not below 1.835). On exposure to the air it rapidly absorbs moisture and becomes less dense. When its specific gravity is 1.78, it deposits crystals of the bihydrated acid at 28°F. , and may burst the glass in which it is kept. Owing to its great affinity for water, it is used in chemistry as a desiccant.

PHYSIOLOGICAL ACTION.—Concentrated sulphuric acid is powerfully corrosive of both animal and vegetable tissues, abstracting the elements of water and leaving the carbon untouched. It consequently *blackens* organic matter at the same time that it destroys its texture.* When administered in therapeutic doses and absorbed into the blood, it is converted into sulphates, and as such, so far as is known, is eliminated.

It escapes by the kidneys, as has been proved by Dr. H. Bence Jones (*Lectures on Pathol. and Therap.*, London, 1867) in regard to large therapeutic doses, and is attested by Maukopff as occurring after poisoning. As, however, the amount of elimination by the kidneys seems to be slight, it is very probable, as Dr. Headland (*Action of Medicines*, London, 1852) conjectures, that it is excreted both by the lower bowel and by the skin. Locally applied, dilute sulphuric acid is an astringent, and clinical experience proves that it exerts a similar action when taken into the system. Under such circumstances its astringent influence is most marked upon the skin and intestine,—parts which are believed to excrete it: it is therefore possible that this action is in a measure local, and dependent upon the presence of the excreted acid.†

THERAPEUTICS.—Concentrated sulphuric acid is not rarely used as an escharotic, for which purpose it is mixed with finely-powdered charcoal so as to form a paste. Appropriately diluted, it has been used as a stimulant and astringent lotion in *venereal* and other indolent ulcers. Internally, sulphuric acid is very useful as an astringent in *colliquative sweats* (*night-sweats*) and in profuse *serous diarrhæas*. I have used it with great advantage in the sudden serous vomiting and purging of infants known as *cholera infantum*.

* The observation of Ore (*Comptes-Rendus*, 1873), that considerable quantities of dilute acids can be injected into the blood without causing coagulation or serious disturbance, has been confirmed by Dr. Paul Guttman (*Virchow's Archiv*, lxi. 534). The acid is probably at once neutralized by the alkali of the blood.

† The action of large but not corrosive doses of mineral acids upon animals has been to some extent studied by Dr. F. Hofmeister (*Prager Med. Wochenschr.*, 1879, iv. 75). Death, he believes, results from asphyxia, due to the acidification in the blood of the alkaline salts, which serve as vehicles in carrying the carbonic acid from the tissues.

It has been employed with advantage in *cholera*, and a remarkable series of observations by Dr. R. G. Curtin (*Phila. Med. Times*, vol. iii. p. 649) at least furnish good reason for further testing its powers as a prophylactic against this disease. The facts recorded by Dr. Curtin are as follows. A very severe epidemic of the disease ceased in the Insane Department of the Philadelphia Almshouse within twelve hours after the lunatics were all put upon the free use of sulphuric acid lemonade; the only new case after this being in a man who refused to use the prophylactic. Two days after the use of the sulphuric acid was stopped, two new cases occurred, and the epidemic was again arrested by the use of the acid. In the surgical wards of the Hospital Department the acid was used from the beginning of the epidemic; and these wards, although in no way isolated, were the only parts of the institution unvisited by the disease.

Sulphuric acid was formerly used in *hemorrhages*, but is now rarely employed. It is, I think, much less efficacious than some other remedies. In *acute lead-poisoning* the dilute acid is an efficient antidote, and it has been proposed by M. Gendrin (Dr. Bennett, *Lancet*, 1856) as a remedy in *chronic lead-poisoning*. As, however, he combined its internal exhibition with the daily use of warm sulphur-baths, it is doubtful how much of the successful result was due to its action. It is difficult to perceive how it can do good in these cases, and I do not think the clinical proof that it does so has as yet been brought forward.

Toxicology.—When swallowed in concentrated form, sulphuric acid acts as a corrosive poison. Death from collapse has resulted in two hours and a half (case, *Med. Times and Gaz.*, vol. i., 1863), but usually the course of sulphuric acid poisoning is much more protracted, the fatal result having been delayed in some cases for several months. The usual symptoms are pain in the mouth, throat, and epigastrium, violent vomiting, often of tarry matters, with symptoms of collapse, such as cold extremities, feeble pulse, suppressed voice, and clammy skin. The mind is generally clear to the last. Profuse, and sometimes bloody, salivation is commonly present. The parotids sometimes swell as early as the fourth day, and Maukopff (*Syd. Soc. Year-Book*, 1863) has seen suppurative parotitis apparently induced by closure of the duct of Steno, retention of secretion, and consequent irritation of the gland. The later symptoms are those of ulceration of the œsophagus and stomach, and need not be dwelt upon here. The larynx is often profoundly affected. There is a very marked increase in the amount of sulphates in the urine, which may be albuminous and contain granular casts. Desquamative nephritis may be developed several days after the subsidence of the first symptoms. Thus, in one of the cases reported by Maukopff, urine which had ceased to be albuminous on the third day became so again on the twentieth, with a simultaneous development of casts containing blood-corpuscles; after death tubular nephritis was found. Another symptom noted by Maukopff was intercostal neuralgia.

After death, greater or less destruction of the œsophagus and the stomach, or of the air-passages, is found. The black color of the slough is a diagnostic sign which an examination of the mouth will sometimes render available before death.

The most important part of the treatment of sulphuric acid poisoning consists in the immediate and free exhibition of the antidotes, which should be given in milk or in water. The best antidotes are chalk, magnesia, whitewash, and soap. Christison condemns the use of the alkaline carbonates, because they are themselves irritating. As, however, in these cases time is a matter of vital importance, if the alkaline carbonates be the only antidotes at hand they should be used unhesitatingly.

ADMINISTRATION.—Sulphuric acid should of course be given properly diluted, and with the requisite precautions to prevent its injuring the teeth. It is best administered in the form either of the *dilute* (*Acidum Sulphuricum Dilutum*—10 per cent. by weight, U.S.; sp. gr. 1.070; dose, ten to thirty drops) or of the *aromatic sulphuric acid* (*Acidum Sulphuricum Aromaticum*—about 20 per cent. by weight, U.S.). The last preparation contains alcohol and aromatics. Its dose is from ten to twenty drops, well diluted.

ACIDUM HYDROCHLORICUM—HYDROCHLORIC ACID. U.S.

Hydrochloric acid is a colorless aqueous solution of hydrochloric acid gas, having the specific gravity of 1.163 and containing 31.9 per cent. by weight of the gas. The hydrochloric or muriatic acid of commerce commonly has a yellowish tint, produced by ferric chloride, or sometimes by organic matter.

PHYSIOLOGICAL ACTION.—In its concentrated form hydrochloric acid is highly corrosive, but less so than either sulphuric or nitric acid. Its astringent properties are not all decided, if indeed it really possess any. As it probably is one of the natural acids of the stomach, it would seem as though it ought to be capable of aiding digestion. It also appears to have influence over the glandular system of the alimentary canal, increasing by its action their normal secretions.

THERAPEUTICS.—In *stomachic dyspepsia*, muriatic acid, with or without pepsin, is often useful by aiding in the digestion of the food. In other cases, where the *dyspepsia* is *intestinal*, with a tendency to diarrhoea and loss of appetite, muriatic acid combined with strychnine and some aromatic, such as compound tincture of cardamom, is often very advantageous. In *low fevers* the use of mineral acids has been highly extolled by various authorities. I have seen a number of cases treated upon this so-called "Swedish plan," and have never been able to perceive that the acids do any real good.

Locally, diluted muriatic acid has been recommended by Bretonneau in *diphtheria*. He employed a mixture of one part of the acid to two parts of honey; but bolder practitioners have used it of full strength,

with, it is asserted, good effect. It should be applied by means of a little mop, scrupulous care being exercised to prevent any of the acid from coming in contact with parts not protected by false membrane.

TOXICOLOGY.—Hydrochloric acid, as a poison, is similar in its effects to, but less powerful than, sulphuric acid, recovery having occurred after the ingestion of an ounce of the officinal acid (*Boston Medical and Surgical Journal*, vol. xv.). The treatment is similar to that of poisoning from other mineral acids.

ADMINISTRATION.—The acid is best given in the form of the officinal *Acidum Hydrochloricum Dilutum* (10 per cent.; sp. gr. 1.050). Dose, ten to thirty drops, properly diluted.

ACIDUM NITRICUM—NITRIC ACID. U.S.

A liquid of the specific gravity of about 1.414, which as first made is colorless, but by exposure to the light acquires a yellow tint. It oxidizes all of the common metals except gold, and is exceedingly corrosive to living tissue, which it stains an indelible yellow. When diluted it converts most animal and vegetable substances into oxalic, malic, or carbonic acid.

PHYSIOLOGICAL ACTION.—When applied to any portion of the living organism, nitric acid acts as a most powerful chemical caustic. When very greatly diluted, it is a simple local stimulant, with very slight astringent powers. Owing to its chemical activity, its vapor was at one time used as a disinfectant; but it has been superseded by other substances. Taken internally in small amount, it acts as a stimulant upon the glandular system of the alimentary canal, and in serous diarrhoea appears to exert an astringent influence. It seems to me very probable that these effects are local rather than constitutional, due to a direct action of the acid upon the mucous membrane of the bowel. On entering the blood, nitric acid must be converted into a nitrate. In regard to its elimination we have but little definite information, but it probably escapes through the same channels as does sulphuric acid.

THERAPEUTICS.—Nitric acid is used quite frequently as an escharotic, especially in cases of *chancres* and *venereal* or other *warts*. In its employment care should be taken to protect the sound tissue by oil, or, still better, by a layer of soap. It may be applied by means of a splinter of wood, or, if it is to be used more freely, by a little mop. When it has penetrated as deeply as is desirable, washing the part with warm soap-suds will prevent further action. Very much diluted (five to twenty drops to the ounce), it forms a good stimulant lotion for indolent *ulcers*. It should not be employed as a mouth-wash, on account of its destructive action on the teeth. Of course this does not apply to its use as a caustic in *cancerum oris*, in which, as in other forms of *acute gangrene*, such as *phagedenic chancres* and *hospital gangrene*, it is very efficient. In these cases it must be applied thoroughly.

Internally, nitric acid has been used in *low fevers*, but with doubtful advantage. In *dyspepsia*, in *chronic hepatic congestion*, in the *oxalic acid diathesis*, in the *dyscrasia of constitutional syphilis*, nitric acid has been employed with advantage, but is much inferior to nitro-hydrochloric acid.

In 1826 Dr. Hope claimed for *Acidum Nitrosum* a specific action in *serous diarrhœa*, including the sudden acute diarrhœas of hot climates, and in the chronic *dysenteries* originating under similar circumstances. The formula he employed is as follows: R *Acidi nitrosi*, fʒi; *Misturæ camphoræ*, fʒviii; *Misce*, et adde Tinct. opii, gtt. xl. S.—A fourth part to be taken every three or four hours. Under the name of *Hope's Camphor Mixture* a preparation similar to this has been much used, but has gradually lost the confidence of the profession, chiefly, I believe, because on theoretical grounds the original formula has been departed from. The *Nitrous Acid* of the shops (*Acidum Nitrosum*, *Edinburgh Pharmacopœia*) is an orange-red liquid, which may be looked upon as a solution of nitric oxide in nitric acid. When it is diluted with water it is after a short time converted into simple nitric acid. For this reason it has been customary to substitute nitric acid for the *Acidum Nitrosum* of Hope's original formula. It should be noted, however, that the latter only provided sufficient of the remedy to last a few hours, and, as the reaction which has been spoken of requires some time for its performance, I do not think that theory in truth warrants the change. Practically I have failed absolutely with the new formula, when immediate relief was afterwards obtained by the use of the medicine prepared according to the old plan. Made in this way and used while fresh, Hope's Camphor Mixture is a very efficient though disagreeable remedy in diarrhœas connected with disordered secretion of the liver and other glands of the alimentary canal.

ADMINISTRATION.—The dose of the strong acid is from five to twenty drops; of the diluted (*Acidum Nitricum Dilutum*—10 per cent. by weight, U.S.; sp. gr. 1.057), from fifteen to sixty drops, well diluted.

TOXICOLOGY.—When taken in a concentrated form, nitric acid is a corrosive poison, exceeding even sulphuric acid in violence. The symptoms so closely resemble those induced by the latter substance that it is unnecessary to detail them here, as is also true of the treatment. The distinguishing character is to be found in the *color* of the affected tissues, which in nitric acid poisoning are stained of a deep yellow.

ACIDUM NITRO-HYDROCHLORICUM—NITRO-HYDROCHLORIC ACID. U.S.

This preparation is made by mixing nine parts of nitric acid with forty-one parts of hydrochloric acid. If the acid be sufficiently strong, an orange-colored liquid will be formed, with the evolution of intensely irritating vapors. After standing for a length of time, the red color changes to a golden yellow. It is in this state that the U.S. Pharmacopœia directs

the acid to be used. By longer standing the *golden yellow* becomes *lemon-yellow*, and the odor of chlorine is almost entirely lost. These changes are hastened by light, but will occur in the dark and in well-stoppered bottles. Although the golden-yellow acid is directed by the Pharmacopœia, yet careful clinical studies have convinced me that the acid acts much more efficiently when freshly prepared and of a deep-red color. In some cases it has seemed to me useful only when in the latter form. The lemon-yellow acid is nearly valueless.

PHYSIOLOGICAL ACTION.—Concentrated nitro-hydrochloric or nitro-muriatic acid is exceedingly corrosive. Our knowledge of its action in small doses is purely clinical, and will be spoken of under the head of Therapeutics. The chemistry of the acid is so complex and uncertain that no reasonable conjecture can be made as to the form in which it is absorbed or the method of its escape from the body. That it is absorbed in some form is proved by its occasionally producing salivation, even when applied to the skin by means of baths.

THERAPEUTICS.—The remedial value of nitro-hydrochloric acid depends chiefly upon the power which it possesses to a much greater degree than any other of the mineral acids of influencing the action of the liver and other glandular organs of the alimentary canal. Originally proposed by Dr. Scott, of Bombay, in the *chronic hepatitis* of hot climates, it has been used with great success by Annesley, Martin, and other famous India surgeons. The remedy would seem not to be indicated in hepatitis with high fever and a tendency to rapid suppuration so much as in the slower form of the affection, which normally ends in chronic enlargement and induration of the viscus. In the habitual congestion of the liver occasionally seen in this climate I have used it with the most marked benefit. In the still milder affection known as "*biliousness*," whose pathology is probably a torpid condition of the small glands of the alimentary mucous membrane as well as of the liver, nitro-muriatic acid has yielded in my hands most excellent results. That the remedy does act upon the liver is proved by the fact that in these cases it sometimes produces violent bilious diarrhœa. When *jaundice* depends upon obstruction or upon any of the severer organic diseases of the liver, the acid is of little if any use; when, however, the jaundice depends upon torpor of the liver, or even when it is catarrhal in origin, the remedy may be of great service. Even in the early stages of *cirrhosis*, while the liver is still enlarged, nitro-muriatic acid should be tried, as in some cases apparently of this character great benefit has been derived from its use.

In those forms of *chronic diarrhœa* in which the disease is really an intestinal dyspepsia, nitro-hydrochloric acid may be of the utmost service, benefiting and even curing cases which have resisted other treatment. As the effect of the acid is not a sudden one, it is evident that it acts in these cases not as an astringent, but by restoring the normal digestive power.

There is a morbid condition, probably dependent upon defective primary assimilation, in which the chief symptoms are general malaise, a feeling of weakness, a lack of elasticity, and a very great depression of spirits, in which crystals of oxalate of lime are generally to be found in the urine, and in which nitro-muriatic acid produces in a few days a surprising revolution.

As a "blood-purifier" the acid has been employed in *constitutional syphilis*, and in various ulcerative *skin-affections*. In these diseases it no doubt does good by improving digestion and increasing glandular action; but there is no reason to believe that it is a direct alterative.

ADMINISTRATION.—For reasons which have already been given, when nitro-muriatic acid is administered internally it should be freshly prepared; and, as the changes which have been spoken of take place more rapidly when the acid is mixed with water, the officinal *dilute* nitro-muriatic acid is an ineligible preparation. As light hastens its deterioration, the strong acid should always be kept in a dark bottle with a glass stopper. Directly after mixing the acids the evolution of gas may be so great as to necessitate its being allowed to escape. After six or eight hours, however, the bottle should be closely stoppered. The dose of the strong acid is from five to eight drops, properly diluted, and taken through a tube after meals.

In *chronic hepatic diseases* the external application of the acid seems to give even better results than its internal use. In India, according to Sir Ranald Martin, the bath is used as follows. Take Hydrochloric acid ℥iii, Nitric acid ℥ii, Water ℥v. Mix. Two gallons of water and six fluidounces of the above mixture suffice for a bath, which will keep fit for use during three days, provided half a fluidounce of acid and a pint of water are added morning and evening. The bath must of course be given in wooden or earthenware vessels, and if it becomes necessary to warm it only a portion should be heated, and the rest then added. In urgent cases the whole body may be immersed in the bath; but generally a foot-bath is preferable, the inside of the thighs and arms and the hepatic region being at the same time sponged. The bath should be repeated twice daily, lasting each time for ten or fifteen minutes.

I have had no experience in this method of using nitro-muriatic acid, but have derived great benefit from the application of the acid over the hepatic region. My plan has been to wring out a large piece (eight by ten inches) of spongio-piline, or of cotton flannel (several layers), in a lotion of a strength varying, according to the irritability of the patient's skin, from one to three fluidrachms to the pint, and to apply this over the right hypochondrium, covering it with a piece of oiled silk supported by a bandage. The application sometimes causes a prickling sensation, and after a time may produce a profuse local sweating. The dressing may be left on from half an hour to an hour,

and be repeated three or four times a day: some patients can wear it almost continuously.

TOXICOLOGY.—When taken in poisonous doses, nitro-hydrochloric acid produces symptoms and results similar to those following the ingestion of nitric acid. The color of the stain produced by it is yellow, and its antidotes are the same as those of other mineral acids.

LACTIC ACID (**ACIDUM LACTICUM**, U.S.) appears to be the natural acid of the gastric juice, and may with propriety be used as an adjuvant to pepsin in doses of half a drachm three times a day. W. Proyer, conceiving that sleep is due to the presence in the blood of the results of tissue-change, among which is lactic acid, experimented with it and its soda salt, and announced that they acted as powerful soporifics upon both man and the lower animals (*Centralbl. f. Med. Wissens.*, 1875, p. 578). According to his statements, with the sleep came deep, slow respiration, and lessening of reflex activity and of the bodily temperature. Subsequent papers by Dr. E. Mendel (*Deutsch. Med. Wochenschr.*, 1876, No. 17), Dr. Erler (*Centralbl. f. Med. Wissens.*, 1876, p. 658), Dr. Fischer (*Lond. Med. Record*, 1877, p. 193), Dr. Lothar (*Virchow's Archiv*, lxxi. 120), and Dr. Senator (*Berlin. Klin. Wochenschr.*, 1877, p. 637), have shown that the hypnotic powers of lactic acid and its salts are very feeble and uncertain. The large doses used also are very prone to produce irritation of the alimentary canal, and Senator noticed the production of rheumatic pains. From three to nine drachms of the lactate of sodium may be given at a dose.

FAMILY III.—ALTERATIVES.

THERE are employed by practitioners of medicine, to affect certain diseases most intimately connected with the processes of nutrition, various substances which do not, at least in the doses commonly used, produce any very obvious symptoms. These drugs may perhaps neither stimulate nor depress, so far as can be perceived, any function of the body; their action may be silent and imperceptible, their mode of influence may be unknown; but their therapeutic effects are among the most assured of clinical facts. It is to medicines of this character that the name of *Alteratives* has been applied, because when administered they seem simply to alter morbid processes.

Speculation has been rife as to the mode in which alteratives influence the body; and as the accepted pathology has been humoralistic or otherwise, so has it been strenuously argued that they act upon the vital fluid, or upon the solids of the body. The term "purifying of the blood" has been especially applied to their action, and is sufficiently suggestive of their function as viewed from the pathological standpoint of the old humoralist. What we know of the action of these medicines at present amounts to this, that they modify the nutritive processes of the body. As the *physiologist* has scarcely learned the alphabet of that part of his science which treats of the general nutrition, having no positive knowledge as to what is the real dominant force in the nutritive processes,—as the *pathologist* is completely baffled in attempting to find the essence, as it were, of the morbid processes which are successfully met by alteratives,—as he cannot point out to us what perverted functions underlie these diseases as their basis,—why should the *therapist* be expected to explain the rationale of his treatment? The empirical facts of the clinical pathologist are met by the empirical facts of the clinical therapist. It is absurd to gaze into mid-air for the crowning spire before the foundation-stones of the temple are laid.

To deny, as has been done, the existence or value of medicines of this class because we cannot tell why mercury relieves syphilis or why iodide of potassium cures rheumatism, is as absurd as to deny the existence of the syphilitic and the rheumatic dyscrasia because we do not know their ultimate nature. Let us be content, until more light comes, to hold fast to the clinical facts, each believing for himself, if he choose, that alteratives alter nutrition by affecting the functions of the

blood-making organs, or, if he prefer, that they act by impressing the cells of the body directly; or, what is even more philosophical, each holding his mind free from belief, an unoccupied tablet on which the truth may readily be inscribed when it is discovered.

PHOSPHORUS. (P.) U.S.*

Phosphorus is a translucent, when pure nearly colorless, but usually slightly yellowish, highly inflammable elementary body, which is tasteless, but possessed of a peculiar alliaceous odor. It is obtained from the phosphate of calcium of calcined bones, by taking away the lime with sulphuric acid and deoxidizing the residuum by heating with charcoal. It is insoluble in water, sparingly soluble in ether, absolute alcohol, and the oils, freely so in chloroform. It takes fire at 100° F., and melts at 111.2° F. In the shops it is in cylindrical sticks, covered with a whitish layer, and having when cut a waxy consistence and lustre. When properly treated, it is converted into several allotropic forms, the red phosphorus, black phosphorus, and the crystallized metallic phosphorus of Hittorf. The first of these is the most important; it is brittle, does not take fire at ordinary temperatures, and is said not to be poisonous.

PHYSIOLOGICAL ACTION.—The physiological action of phosphorus in therapeutic doses is probably entirely different from that which it exerts when in larger amounts. It is a constituent of most of the more important tissues, and is especially abundant in the nerve-centres. Like iron, cod-liver oil, etc., it appears to act when given in minute quantity as a stimulant to the nutrition of the tissues, into whose composition it enters. So far as the nervous system is concerned, this assertion rests chiefly upon clinical observation; but Dr. Wegner (*Virchow's Archiv*, June 22, 1872) has experimentally demonstrated such an action upon the bony tissues. He found that when adult animals were fed upon minute doses of phosphorus the spongy tissue in the long and short bones was thickened, and the compact tissue was rendered more dense. After a time new tissue was deposited upon the inside of the shafts of the long bones, in some instances until the marrow-cavity was obliterated. The action upon the bones of growing animals was even more marked.

Phosphorus was at one time believed to be a diffusible stimulant, and it possibly may exert such an influence. In the acute nervous exhaustion of *typhoid pneumonia* I have once or twice seen it apparently act favorably in this way.

For reasons to be hereafter adduced, it is certain that in poisonous

* In previous editions of this book Phosphorus closed the chapter on Tonics; in this edition it opens the chapter on Alteratives. In fact, it affords a natural transition between the two classes; but in its affecting the general nutrition and in its producing wide-spread fatty degeneration it seems to be more closely allied to arsenic than to the ordinary tonics. It must be remembered that arsenic is used as a tonic almost as much as is phosphorus.

doses phosphorus acts as phosphorus, and when it is administered therapeutically it certainly enters the blood in its elemental form, and, I believe, acts as such. Dr. Wegner advances the following reasons for believing that it does not act as phosphoric acid so far as the bony tissues are concerned. First, no similar action can be obtained from phosphoric acid unless from eight hundred to one thousand times the proportional dose be given. Second, the newly-formed tissue is at first gelatinous. Third, there is no excess of phosphates in the bone. Fourth, when the food is deprived of lime the same new tissue arises, but remains in a soft, gelatinous state.

THERAPEUTICS.—The chief use of phosphorus in medicine is as a nutrient tonic to the nervous system. In all cases of chronic *nervous exhaustion*, whether involving the cerebral or the spinal centres, it is of great value. I have seen marked benefit from its use when the symptoms were not severe enough to indicate organic lesion; but the most remarkable results have been in the cases in which the structure of the centres was apparently deeply implicated. In threatening *cerebral softening*, in *myelitic paraplegia* from excessive venery, it is the only drug which appears really to affect the nerve-centres.

Attention has recently been called by several writers to its virtues in *neuralgia*; and, as neuralgia is often simply an expression of exhausted nerve-power, the use of phosphorus is commended by reason as well as by experience.

It is probable that it may be of value in some cases of impaired vitality, although the nervous system be not obviously implicated. Dr. H. Eames (*Dublin Journ. Med. Sci.*, Jan. 1872) states that he has obtained great benefit from its use in obstinate skin-affections, such as *lupus*, *acne*, and *psoriasis*. It has also been asserted to be useful in *cataract*.*

On account of its marked influence on the development of bone, Dr. Wegner suggested its use in *osteomalacia* and in *rickets*, and Dr. Friese states (*Berlin. Klin. Woch.*, 1877, p. 437) that he has had brilliant success from its use in combination with iron in several cases in which ordinary treatment had failed. The recent elaborate article of M. Kasowitz (*Zeitschrift f. Klin. Med.*, 1884, 115) confirms this specific action of phosphorus, and I think it should be persistently administered to all rachitic children. Professor Samuel R. Percy has used phosphorus successfully for repeated *furuncular eruptions* (*Trans. Amer. Med. Assoc.*, 1872, p. 659).

TOXICOLOGY.—The ingestion of a fatal dose of phosphorus is not followed by any sensible effects for some time. After, however, from three to twelve hours a sense of weakness and of general wretchedness manifests itself, and in a large proportion of the cases (according to Lewin, eighty-eight per cent.) is accompanied, or soon followed, by

* Dr. Taignot, *Revue de Thérapeutique Médico-Chirurgicale*, August and September, 1871; Professor Giuppi, *Giornale d'Oftalmologia*, abstract in *N. Y. Medical Record*, 1872.

vomiting. With the emesis there is nausea, and in most cases the patient soon complains of abdominal pain, the severity of which, however, never equals that of corrosive poisoning. The matters vomited consist of food, mucus, and bile. During the first eight or ten hours they often smell strongly of phosphorus, and are luminous in the dark. The vomiting may persist during the whole attack, but generally ceases on the second or third day, to reappear with the subsequent jaundice, when coffee-colored vomit from exuded blood is ejected. The pain, which in most cases abates with the vomiting, often spreads from the epigastrium over the whole abdomen, and in rare instances is paroxysmal. If it reappear in the latter stages, it is apt to affect especially the right hypochondrium, and is associated with decided tenderness in the region named and in the epigastrium.

The tongue is whitish or abnormally red, sometimes furred. There is generally fever, loss of appetite, and thirst. Maukopff has noted a morning and evening temperature of from 37° C. to 39° C. and from 37.4° C. to 39.8° C. respectively. During the latter part of the case there is very often a remarkable fall in the temperature, which is generally, but not always, a precursor of death. The lowest point I have seen noted was 31.2° C. (88.2° F.) some hours before death.* In some cases fever is altogether absent, or comes on just before death.†

The stools are at times normal in character and frequency, but there is general diarrhoea or constipation, with flatulence. Late in the attack the passages are in most cases very light clay-colored, or even whitish, and exceptionally they are bloody. In some cases they are phosphorescent.

Jaundice comes on in from thirty-six hours (cases reported by Maukopff, *Wien. Med. Wochenschr.*, 1863, and by Tüngel, *Klin. Mittheilungen Abtheilung des Allgemein. Krankenh. in Hamburg*, 1861) to five days (Lebert and Wyss, *Archives Générales*, 6th series, xii., Sept. 1868) after the ingestion of the poison. In most cases it appears first in the conjunctiva, but sometimes the urine gives previous warning of its approach. In some cases there is with it a decided and palpable increase in the size of the liver, which may pass, if the patient live long enough, into an equally apparent lessening of the bulk of the viscera. The severe nervous symptoms are rarely, if ever, developed until after the jaundice, although early in the attack there is not unfrequently anxiety, headache, giddiness, and dreamy unquiet sleep, or even sleeplessness. The more pronounced nervous symptoms consist of delirium, which may be wild and is very frequently erotic, with somnolence ending in coma and death, occasionally preceded by convulsions. According to Taylor, the latter are a certain sign of approaching dissolution. Very generally, partial spasms and fibrillar contractions of the voluntary

* See case of Dr. Buttman, *Archiv der Heilkunde*, 1871, p. 257.

† See case of Conesto, *Sydenham Soc. Year-Book*, 1869-70, p. 454.

muscles occur, although there is always, in not too rapid cases, progressive paresis of the voluntary muscles. Death is usually put off beyond twenty-four hours, yet it has occurred in a child in four hours and in the adult in seven hours (*Wien. Med. Wochenschr.*, May, 1884); also in nine hours (*Prag. Med. Wochenschr.*, xiv., 1889). The patient may suddenly succumb to collapse and cardiac paralysis, but more commonly dies comatose from a gradual failure of respiration and circulation.

If recovery occur, it is by a gradual amelioration of the symptoms, and the health of the patient is apt to be impaired for some time. Apparently desperate cases will sometimes convalesce unexpectedly; and Tüngel states that a favorable issue may take place even after violent delirium.

The urine is almost always much affected by the poison. Very commonly it is scanty, is albuminous, and sometimes it contains sugar. As was first pointed out by Munk and Leyden (*Die acute Phosphorvergiftung*, Berlin, 1865), after jaundice has set in, bile-acids, as well as biliary coloring-matter, are always to be found in the urine. Not unfrequently a cloudy sediment consisting in part of epithelial cells, often tinged with bile, is deposited. Dr. Oswald Kohts (*Pflüger's Archiv*, Bd. iii. p. 1) and other observers have found leucin and tyrosin in the urine of dogs poisoned with phosphorus, and undoubtedly these substances are sometimes to be met with in the human excretion. The albuminuria generally follows, but may precede, the icterus. A very remarkable and apparently constant constituent of the urine is the sarco-lactic acid. Fat has been found in the urine inside of renal epithelial cells, and also as free globules (Schütz, *Prag. Med. Wochenschrift*, 1882, vii. 322).

Phosphorus induces in animals symptoms parallel with those commonly seen in man; although Kohts states that he has seldom seen albuminuria in animals, even when the structure of the kidneys was profoundly altered. Orfila, Magendie, Munk, and Leyden found that the only effects following the injection of phosphuretted oil into the jugular vein of an animal were the exhalation of phosphoric acid and broncho-pulmonary inflammation: on examination (Munk and Leyden), oil, but no phosphorus, was found in the lungs. Ludimar Hermann and Alfred Brunner (*Deutsch. Arch. f. Klin. Med.*, p. 198) have shown that in these experiments there was embolic arrest of the oil in the pulmonary capillaries, and consequent inflammation with subsequent oxidation of the phosphorus. When the phosphuretted oil is injected in the form of a fine emulsion, the characteristic symptoms and post-mortem appearances of phosphorus-poisoning result.

In some instances phosphorus-poisoning presents symptoms quite different from the typical array. Death may take place in a few hours, and in such cases jaundice is not generally present (case, *Lancet*, 1879, ii. 311). Zeidler reports a death in forty-two hours, from suppression of urine, with collapse and erotic delirium. In a case of Bollinger's

(*Deutsches Archiv f. Klin. Med.*, Bd. vi., 1870) the chief symptoms were vomiting, pain and tenderness over the abdomen, great weakness of pulse, gradually-developed paralysis of the legs, and death, without jaundice, in four and a half days. The autopsy revealed hemorrhagic effusion between the membranes and the spinal cord, and also into the sheaths of the proximal portions of the spinal nerves.

In women, fatal doses of phosphorus very commonly produce a bloody pseudo-menstrual discharge, and when pregnancy exists almost invariably induce abortion or miscarriage. M. Miura has found in the fœtus of poisoned rabbits structural changes similar to those of the mother (*Virchow's Archiv*, xvi. 54).

The older toxicologists spoke of an erosive gastritis as a common result of phosphorus-poisoning, but it is now well established that such affection is very rarely induced by the drug.* As was first pointed out by Virchow (*Virchow's Archiv*, Bd. xxxi., 1864), there is universally a gastro-adenitis, which causes the gastric mucous membrane to be thickened, opaque, whitish, grayish, or yellowish-white. Under the microscope the epithelial cells appear swollen and filled with granules and oil-globules, and in very advanced degeneration the cells completely break down. This gastro-adenitis is not due to a local action of the phosphorus, because it occurs when the poison is introduced through other channels than the mouth. The duodenum and intestines suffer similar changes. The liver is generally very much enlarged, friable, and light-colored; sometimes it is mottled, and sometimes portions of it are deeply stained with bile.† The cells are gorged with fat-globules,‡ and in some cases there are small-celled interstitial thickenings due to hyperplasia of the trabecular tissue. The gall-bladder may be full or empty. In protracted cases the liver undergoes atrophy, with destruction of its secreting cells. According to the researches of Dr. Arthur Hefter (*Archiv f. Exper. Path. u. Pharm.*, xxviii, 1891), the

* It would appear probable that if it occurred at all it would be in rapidly-fatal cases; yet Tügel did not find it in a patient dead in nine hours of phosphorus-poisoning (*Virchow's Archiv*, Bd. xxx., 1864).

† According to researches made by Dr. Emile Rousseau in the Pathological Laboratory of the University of Pennsylvania, the first anatomical changes in the liver occur in the centre of the lobules around the hepatic vein.

‡ A. Lobodoff (*Arch. f. Physiol.*, xxxi. 11, 1883) believes that the fat in the liver is not produced by degeneration of the hepatic tissue, but has simply been transported there from the subdermal regions. He bases this opinion upon his own observations,—first, that the phosphorus fat has the same chemical constitution as has the subdermal fat; second, in a dog which had been fed with linseed oil and then poisoned with phosphorus, the liver was loaded with linseed oil. This evidence is of very little value, because on the one hand the linseed oil probably accumulated in the dog's liver before the poisoning and simply remained over, and on the other hand there is no proof that fat produced by degenerative changes necessarily differs in composition from other fat. The fact that the liver and other organs are destroyed in phosphorus-poisoning may be considered proof that the fat is formed out of the affected tissue; although this seems contrary to the allegations of Bergeat (*Oestrich. f. Morph. u. Physiol. München*, 1884), that in very emaciated animals the phosphorus-poisoning may run its course without the formation of fat.

percentage of lecithin in the liver, which is fixed in health, is greatly lessened in phosphorus-poisoning. The kidneys, especially in their cortical portion, suffer a degeneration similar to that of the liver, the epithelium becoming enlarged, granular, fatty, and finally undergoing destruction. In some cases, even with the naked eye, yellowish streaks can be seen following the course of the urinary canals, from the papilla into the cortex. These are due to epithelial fatty degeneration, and have been thought to be pathognomonic of phosphorus-poisoning; but Paltauf has shown that they may be at least simulated in other conditions. The voluntary and cardiac muscles, the spleen, the lungs, and probably all the tissues, partake of the universal fatty degeneration* which Wegner has shown to involve even the minute arterioles.

The blood is often profoundly affected,† becoming very dark, losing its power of coagulation, and apparently suffering also in its corpuscular elements; for ecchymoses are almost universal, and hæmatin crystals are occasionally found in the viscera. In the case of Concato (*loc. cit.*) the white corpuscles were observed during life to be increased in number, and the red to be diminished in size and altered in form. The ecchymoses occur in all parts of the body, but are apt to be especially pronounced in the mediastinum and the serous membranes. Schiff has found that in dogs, after death from phosphorus, the blood does not pass into the veins, but remains in the arteries (*Archiv f. Exper. Path. u. Therap.*, Bd. ii. p. 374.) Dr. O. Silbermann states that thrombi are formed in the blood-vessels (*Archiv. Path. Anat.*, 1889, cxvii.).

It should be remembered that although some or all of the lesions which have just been described are usually found in the body of persons dead of phosphorus-poisoning, it is possible for the poison to take life very rapidly and leave no trace of its influence; there being not even sarcolactic acid in the urine (see case reported by Paltauf, *Wien. Klin. Wochens.*, 1888). According to the researches of Professor W. W. Podwysotsky (*St. Petersburg Med. Wochens.*, 1888), in rapid cases the first change in the body consists in the formation of little whitish-yellow

* For a full discussion of the pathology of phosphorus-poisoning, see *Études cliniques et expérimentales sur l'empoisonnement aigu par le Phosphore*, Professor H. Labert et Dr. O. Wyss (*Archives Gén.*, Sept. 1868); *Zur pathologischen Anatomie der acuten Leberatrophie und der Phosphorvergiftung*, Dr. Otto Bollinger (*Deutsches Archiv f. Klin. Med.*, Bd. vi., 1882); and *Ueber Icterus bei Phosphorvergiftung*, Dr. O. Kohts (*Ibid.*); Ziegler (*Heidelberg Path. Anat.*, Bd. II.; G. Krong, *Virchow's Archiv*, 1887, ex.).

† Dr. Mayer states that when very large doses of the poison have been taken, the blood and even the urine (?) may be phosphorescent (*Canstatt's Jahresbericht*, 1862, Bd. v. p. 133). Otto Taussig, as the result of a series of blood studies in phosphorus-poisoning, reaches the somewhat remarkable conclusion that in man, usually at about the acme of the symptoms, there is either a suddenly developed or a slowly produced increase of the red blood-corpuscles, without an increase of the hæmoglobin of the blood and with a distinct lessening of the leucocytes, whereas in the rabbit there is no alteration in amount of hæmoglobin or number of red disks, but a plain increase of the white corpuscles; and in chickens there occurs an enormous destruction of the red disks, with a marked leucocytosis (*Archiv f. Exper. Pathol. u. Pharm.*, 1892, 30).

neerotic foci in the liver. The anatomical changes in the liver in phosphorus-poisoning are sufficient to confirm the statements of Schultzen and Riess, that in the poisoning there is arrest of glycogen and sugar formation.

The elimination of bile acids in the urine shows that the jaundice of phosphorus is caused not by an arrest of secretion, but by an occlusion of the biliary passages and consequent resorption of the bile.* Dr. O. Kohts (*loc. cit.*) has apparently demonstrated that the occlusion is most frequently due to the duodenitis involving the common duct, so as to obliterate its lumen by the swelling of the mucous membrane. In some cases, however, it is probable, as believed by Wyss, Alter, and Ebstein, that a catarrhal inflammation of the minute gall-ducts is the cause of the jaundice, and also that the result is in part effected through pressure upon those ducts by the swelling of the glandular and trabecular tissue.† It is proper to state that Demarbaix and Willmart (*Presse Méd.*, xxi., 1869, and *Schmidt's Jahrb.*, Bd. cxliv. p. 152) insist that the icterus is not really hepatogenous, but hæmic in origin, chiefly because they have found hæmatoidin in the urine. This fact, however, proves only that the blood is altered by the poison: it does not disprove the liver-origin of the jaundice.

Acute phosphorus-poisoning so closely resembles yellow atrophy of the liver that their clinical distinction is sometimes difficult, nay, impossible. Distinct phosphorescence in the breath, vomit, or stools would, of course, be direct evidence of poisoning. This phosphorescence, however, very often cannot be detected: according to Votter (*Virchow's Archiv*, Bd. lii. p. 136), it can be rendered more evident in the vomit, stools, etc., by acidifying with sulphuric acid and warming in a shallow dish. When death ensues during the first week of phosphorus-poisoning, the enlarged liver affords a distinctive proof of poisoning; but when the case is more protracted, the atrophied liver of phosphorus cannot be distinguished from that of the natural disease. The symptoms during life rarely, if ever, afford sufficient ground for a positive diagnosis. The lull in the symptoms after the first onset of the disease happens more generally in phosphorus-poisoning than in yellow atrophy. Yet the clinical differences between various cases of either affection are greater than those which have been relied upon as

* E. Stadelmann (*Archiv f. Exper. Path. u. Pharm.*, xxiv., 1888) states, as the result of his experiments made upon dogs, that so far as the secretion of bile is concerned three stages can be made out. In the first stage there is irritation of the liver and increase of the formation and excretion of biliary coloring-matter; in the second stage the gall becomes mucous and cloudy, and the production and separation of biliary coloring-matter is loosened (it is in this stage that the icterus begins); in the third stage the gall becomes again clear, dark, and more rich in biliary coloring-matters, so that the normal excretion of biliary coloring-matter is notably surpassed.

† For an elaborate discussion of the cause of jaundice, see Kohts's paper, *Deutsches Archiv f. Klin. Med.*, Bd. v. p. 169; consult also that of Dr. Bollinger, *Centralbl. für die Med. Wiss.*, 1869, and *Deutsches Archiv f. Klin. Med.*, Bd. v., 1869.

separating the two affections. Köhler has asserted that oxymandelic acid in atrophy of the liver replaces the sarco-lactic acid of phosphorus-poisoning, and stress has been laid upon the asserted facts that in the natural disease leucin and tyrosin are present in abundance in the urine, while in the poisoning they are absent. In yellow atrophy, however, tyrosin is not unfrequently absent from the urine, and leucin present in very small amount, while both principles may be present in phosphorus-poisoning.* In regard to the acids in the urine, very careful chemical analysis would in any case be necessary to determine their presence, and sufficient evidence is certainly not yet forthcoming to show that either of them is really characteristic. Chemical examination is therefore absolutely necessary in all medico-legal cases. (For discussions of the diagnosis between yellow atrophy and phosphorus-poisoning, see Köhler, *Syd. Soc. Year-Book*, 1870, p. 455; Schultzen and Ries, *Annalen des Berlin. Krankenhauses*, Bd. xv., 1869; and especially Dr. I. Ossikovsky, *Wien. Medizin. Presse*, xiii., 1872, abstracted in *Schmidt's Jahrb.*, Bd. cliv. p. 15. For cases in which the question was legally raised, investigated, and discussed, see *Schmidt's Jahrb.*, Bd. cxli. p. 167; *Syd. Soc. Year-Book*, 1832, p. 430; *Annales d'Hygiène*, Jan. 1869.) According to M. Poulet (*Gaz. Méd. de Paris*, Aug. 1872), phosphorus is eliminated as hypophosphoric acid, and the poisoning can be recognized by heating the urine with nitric acid to calcination. If hypophosphoric acid be present, as dryness is reached the mixture suddenly bursts into a flame like a packet of matches.

It has of late years been demonstrated that phosphorus passes into the blood as phosphorus, and not in the form of phosphoric acid or other compound. In poisoning-cases in men the breath is said sometimes to be distinctly phosphorescent; and in animals Bamberger has found phosphorus in the blood, and Husemann and Marme in the liver, two or three hours after its ingestion; W. Dybkowsky (*Hoppe-Seyler's Med.-chem. Untersuch.*, Heft i. p. 54) has detected it in the blood and liver ten hours after its ingestion; and other observers have demonstrated its presence in almost all of the tissues. It seems probable that to some extent it finds entrance into the circulation by being dissolved in the various fatty matters contained in the alimentary canal. At the temperature of the body, however, it yields abundant vapors, and Bamberger has demonstrated that these readily and rapidly pass through animal membranes. He has found that defibrinated blood, when separated from the fumes of phosphorus only by an animal membrane, rapidly becomes saturated with the poison. Dybkowsky (*loc. cit.*) has confirmed this, and it cannot be doubted that in a similar manner living blood absorbs the poison from the alimentary canal.

* Cases (*Wiener Med. Presse*, 1872; *Schmidt's Jahrb.*, Bd. cxix. p. 127, Bd. cxv. p. 123). Professor Ossikovsky believes that the principles appear habitually about the sixth day of the poisoning, when the liver is still enlarged.

W. Dybkowski (*Hoppe-Seyler's Med.-chem. Untersuchungen*, Heft i.) renders probable the theory of Schuchardt (*Henle und Pflüger's Archiv*, N. F., Bd. viii.) that the phosphorus to some extent in the alimentary canal, but much more largely in the veins, is converted into phosphuretted hydrogen, and that some of this compound and some of the phosphorus itself is oxidized in the venous blood, so that phosphoric acid, besides phosphorus and phosphuretted hydrogen, is emptied into the arterial blood; further, that the last two compounds are oxidized at the expense of the arterial blood and the tissues it feeds, and that the poisoning is due to this deprivation of oxygen. For the details of the experiments upon which these conclusions rest I must refer the reader to the original memoir.*

The indications for treatment in phosphorus-poisoning are very evident. It is plain that no medication can influence the terrible organic lesions induced, and that the primary object must be to prevent the absorption of the poison. Emetics and purgatives are, therefore, of prime importance. The necessity of the persistent use of evacuants is shown by the finding of phosphorus by Dr. Starck in the stools three and a half days, and in the vomit two days, after the ingestion of the fatal dose (*Deutsches Archiv f. Klin. Med.*, xxxv. 482). As phosphorus is soluble in oils, no fatty matters should be allowed either in the food or in the medicines. As an emetic, sulphate of copper should always be chosen.

The minute particles of phosphorus adhere so closely to the alimentary canal that they cannot be dislodged by mechanical means, and an antidote is urgently demanded. For the purpose of oxidizing the poison, Duflos suggested magnesia usta and liquor chlorini, and Scherer the chloride of lime; but in practice these substances have been found of no value, on account of the slowness of their action.

The oil of turpentine, originally proposed by Andant (*Journal de Médecine de Bruxelles*, 1868-69) as an antidote to phosphorus,† has been largely used by experimenters, with apparently contradictory results, which, as is now known, were due to the employment of different varieties of the oil. There are in European commerce three varieties of turpentine,—the rectified, the German, and the French. Jonas (*Liebig und Wöhler's Annalen der Chemie*, Bd. xxxiv.) found that while the pure oil has no effect upon phosphorus, the acid French oil forms with it a crystalline, spermaceti-like mass. This is soluble in ether, alcohol, and alkaline solutions, and has received the name of turpentine-phosphoric acid. It is said to be eliminated by the kidneys unchanged, and to exert no deleterious influence. The elaborate experi-

* M. Lecorché (*Archives de Physiologie normale et pathologique*, tome i., 1869, tome ii., 1869) believes that phosphorus acts in the blood as phosphoric acid, but does not establish his opinion. For a discussion of this, see Dybkowski's paper.

† For cases, see *Gazette Hebdomadaire*, 1874; *Schmidt's Jahrbücher*, Bd. clxix. p. 126; *Med. Times and Gaz.*, 1876, ii. 461.

ments of Vetter on dogs and rabbits gave results in accord with these facts, for he found the rectified and German oils to be of no value in phosphorus-poisoning, while the crude acid French oil was distinctly antidotal. Kochler, however, asserts that when the German oil has not been rectified for some time, it acts upon phosphorus. He believes that the oil acts partly by oxidizing the poison and partly by converting it into the harmless turpentine-phosphorous acid. One part of the oil must be given for 0.01 part of the phosphorus. (*Detroit Review*, 1873; from *Med.-chirurg. Rundschau*, June, 1873. Case of recovery, *Guy's Hospital Reports*, xxvi. 13. See also Bène, *Bordeaux Thesis*, No. 84, 1887.) Ordinary American oil of turpentine and Canada balsam are of no value in phosphorus-poisoning.

As was pointed out by MM. Eulenburg and Guttman (*Aertzl. Literaturblatt*, 1868, No. 12, quoted in *Syd. Soc. Year-Book*, 1868, p. 450), and subsequently by Professor Bamberger (*Wiener Med. Presse*, Jan. 1872; *Virchow's Archiv*, June, 1872), phosphorus in a solution of a soluble salt of copper becomes immediately black, owing to the formation of a phosphide of the metal. Professor Bamberger (*loc. cit.*) also asserts that, while this change is very rapid, that induced by turpentine is a slow one, and, from an elaborate series of experiments upon animals, concludes that copper is much the more valuable and certain antidote. Antal appears to have been the first to use the potassium permanganate as an antidote to phosphorus, and in a series of experiments upon dogs Dr. E. Q. Thornton found it much superior to copper sulphate (*Therap. Gaz.*, 1893). The hydrogen dioxide appeared, in Thornton's experiments, to be valueless. In human poisoning, sulphate of copper should be given in dilute solution, three grains every five minutes until vomiting is induced. After this the potassium permanganate should be freely administered, or, as was successfully done by Dr. Hajinos, the stomach may be washed out with its solution; later, the sulphate or citrate may be given as a quickly acting purge, and symptoms met as they arise.

Match-makers and other artisans who are exposed by their occupations to the fumes of phosphorus suffer from chronic poisoning, which, while in many cases it profoundly affects the vitality of the sufferer, is especially distinguished by the occurrence of necrosis of the upper or lower jaw. It has long been known that those artisans who have bad teeth are especially liable to be seriously affected, and the experiments of Wegner have demonstrated that the necrosis of the jaw is due to the local action of the vapor of phosphorus upon the part. He found that when rabbits were kept in an atmosphere full of the fumes of the poison no necrosis ever occurred, unless, by means of an unsound tooth or an artificial wound, the atmosphere had access to the bone. If such access were, on the other hand, allowed to any bone of the body, periostitis and subsequent necrosis resulted. Further, when rabbits received continuously small doses of the phosphorus by the mouth, no

neecrosis occurred even after wounds which laid bare the bones. As phosphorus-neecrosis belongs to the province of the surgeon rather than of the physician, I shall not discuss it further here.

ADMINISTRATION.—Phosphorus may be given in pill or in solution. The *Oleum Phosphoratum*, U.S., containing one per cent. by weight of phosphorus, may be given in doses of one to three minims in aromatized emulsion or in capsules. The *Pilulæ Phosphori*, U.S., or officinal pills of phosphorus, contain one-hundredth of a grain each. In regard to the dose of phosphorus, I have found that many stomachs will not bear more than the fiftieth or even the hundredth of a grain if given in the liquid form; but I have given as high as the twentieth of a grain of the solid drug. Dr. J. A. Thompson has used it in much larger doses (*Practitioner*, July, 1873), prescribing one-twelfth of a grain as an average dose, and in one case having given as high as one-fourth of a grain every four hours without injury. On the other hand, Dr. Anstie has seen slight poisoning from three-fourths of a grain taken in small divided doses during seven days (*Practitioner*, Aug. 1873).

ZINCI PHOSPHIDUM, U.S.—Zinc Phosphide has been largely used, with asserted good results, as a substitute for phosphorus. According to the researches of Vigier (*Bull. Thérap.*, xc., Jan. 1876), it would seem that the phosphide yields its phosphorus within the economy, probably to form a phosphuretted hydrogen. He found that it killed rabbits more quickly than did a corresponding dose of phosphorus, and that both symptoms and lesions were identical in the two cases. The phosphide should be given in pill or granule. The dose may be considered as from one-twentieth to one-twelfth of a grain. Professor Seguin recommends doses of from one-fourth to one-sixth of a grain.

ACIDUM ARSENOSUM—ARSENOUS ACID. U.S.

White Arsenic, *Arsenic*, or *Arsenic Trioxide*, as first prepared by sublimation from the ores, is in transparent masses, but on keeping becomes milk-white externally. It is soluble in water, has a vitreous fracture, is odorless, of a faint sweetish taste, and volatilizes without fusion "at a temperature of 424.4° F." When it is put upon red-hot iron it emits a garlicky odor, owing to its being first reduced to a metallic state and then volatilized.

PHYSIOLOGICAL ACTION.—When applied to any part in a concentrated form, arsenic is a very active escharotic, and even when very much diluted it is a severe irritant. When a single dose of just sufficient size to be felt is ingested, colicky pains, diarrhœa, and perhaps nausea result. After a very large toxic dose, in from one-quarter to three-quarters of an hour an intense burning pain is felt in the œsophagus and stomach, soon spreading to the whole belly, and often accompanied by a sense of constriction at the throat, and an acrid, metallic taste. In a very short time violent vomiting and purging come on.

The matters rejected are at first mucous, and variously colored by the contents of the primæ viæ; but they soon become bilious, and often yellowish or greenish, and finally serous, with mucoid flakes and a greater or less amount of blood. As the case progresses, the symptoms mentioned increase in intensity, and to them are soon added others of different nature. The thirst is excessive; the urine is suppressed; the extremities are icy cold; the pulse is small, feeble, and frequent; the rapid and labored respiration is very much embarrassed and painful from the abdominal tenderness; the surface is dark and cyanosed; violent cramps add their torture; exhaustion deepens into collapse; convulsions or coma ensue, and death occurs in from five to twenty hours.

In another set of cases, when the dose has been smaller or the subject less susceptible, the termination is not reached so soon. After symptoms similar to but less violent than those just described have lasted from a few hours to one or two days, a remission occurs; the purging and vomiting grow less frequent, or perhaps intermit; even the abdominal tenderness may in great measure disappear; but the persistent thirst, cold extremities, and albuminous urine show that the danger is not overpast, and after a time the case puts on a more alarming aspect. Fever develops, the tongue becomes dry and red, the belly very tumid, the abdominal pain more severe, dyspnoea and cyanosis come on, the face is swollen, nervous symptoms, tremblings, cramps, and convulsions appear, and finally an icy coldness pervades the frame, and death occurs in from two to six days. The mind is generally clear to the last. An eruption very frequently appears, sometimes as early as the second day, sometimes not until the fifth. Its character is various: thus, it may be petechial, urticaria-like, papular, vesicular, or pustular. (See Imbert-Gourbeyre, *Moniteur des Hôpit.*, 1857; also A. Huber, *Zeitschr. Klin. Med.*, 1888.)

Such are the ordinary phenomena of acute arsenical poisoning; but anomalous cases are not very rare. Immediate profound collapse, without abdominal pain, is said to have been the chief manifestation in some cases. I myself have seen heavy sleep as the most marked symptom, the sleep, however, being interrupted at intervals by wild outcries and writhings, evidently the outcome of abdominal pain, although no statement could be obtained from the patient. Again, serous purging may be the chief symptom, and arsenical poisoning has been mistaken for cholera, not only during life, but also on the post-mortem table (*Virchow's Archiv*, 1870, Bd. I.).

When arsenical poisoning is not fatal, the convalescence is apt to be slow, and interrupted by various disorders. Prominent among these are affections of the alimentary canal, due to the structural changes produced by the poison. Nervous symptoms are common, and may affect the motor or sensory sphere separately or combined. In some cases they have developed very suddenly (*N. Y. Med. Journ.*, 1850, 177).

I have seen anæsthesia of the feet as the only symptom; motor paralysis may exist alone, but it is usually accompanied by anæsthesia, hyperæsthesia, loss of temperature-sense, great feeling of coldness, or other disorder of sensation, and not rarely excessive pain, which may be aching or lancinating. Occasionally there are severe cramps. The normal sensibility is usually regained before normal motility. Of one hundred cases of arsenical paralysis collected by Imbert-Gourbeyre (*Des Suites de l'Empoisonnement arsénicale*, Paris, 1881), in more than half all the extremities were affected; about one-fourth were paraplegic; in the remainder there was homiplegia or local palsy. Most frequently the paralysis was not pronounced above the elbow or knee. The lamed muscles are usually sensitive to pressure (C. Gerhard, *Sitzungsb. Physik. Med. Gesellsch. Würzburg*, April, 1882),* and undergo rapid atrophy, losing very early their electro-muscular contractility, or presenting the "reactions of degeneration." This poisoning resembles sub-acute poliomyelitis, but differs in the frequency of pain and other sensory disturbances, and in the tendency towards more or less complete recovery. I have seen recovery when the muscular remnants on the wasted limbs had for many months been unable to respond to any form of galvanic current; and out of Imbert-Gourbeyre's one hundred cases all got well except three. Dr. N. Popoff found, in dogs killed in a few hours by a dose of arsenic, the spinal cord inflamed; after slower poisoning there were masses of "exudate" in the neighborhood of the blood-vessels, and in very protracted cases the walls of the spinal arterioles were found to be thickened and the large cells of the gray matter profoundly altered. The protoplasm first became opaque and granular; the nuclei grew fainter and fainter, and finally disappeared; vacuoles appeared, and encroached more and more on the shrunken body of the cell, which finally disappeared (*Virchow's Archiv*, Bd. xciii., 1882; also cxiii., 1888). In the elaborate experiments, however, of Dr. C. Alexander (*Breslau Thesis*, 1889) upon rabbits, the spinal cord was found to be healthy, but the nerve-trunks were in a condition of degenerative atrophy, and the muscles themselves had undergone changes which were believed to be the result of coagulation-necrosis. That arsenic is capable, in man, of producing a myelitis especially affecting the multipolar cells of the cord is shown by the autopsy reported by Drs. Erlicki and Rybalkin (*Archiv f. Psych.*, xxiii., 1891-92). In this case there was no tenderness of the nerve-trunks, so that there appear to be two forms of arsenical paralysis,—one due to myelitic change, the other to a wide spread multiple neuritis,—the diagnosis between the two being made by the presence or absence of nerve-tenderness. It is very probable that in some cases both lesions are present. (See also

* Consult also Renuer, *Ueber ein Fall von chron. Arsenvergift.*, Würzburg, 1876; W. P. McIntosh, *N. Y. Med. Record*, Feb. 1886, 145; Saguin, *Journ. Nerv. and Ment. Diseases*, Oct. 1892, vii. 665; C. K. Mills, *Trans. College of Physicians of Philadelphia*, 3d series, vi.; *Archives de Physiol. Norm. et Path.*, 1884, iv.

Wiener Klin. Wochensh., Bd. iv., 1891.) In some of these cases trophic changes are pronounced: thus, I have seen a growth of hair several inches long cover the wasted limbs. If in any case of arsenical paralysis there were no sensory disturbance, the probabilities would be very strong that the lesion was a toxic poliomyelitis.

The most obvious lesions found after death from acute poisoning by arsenic are in the stomach and bowels, even when the poison has found entrance into the system through other channels. The gastric mucous membrane is usually swollen, maculated with patches of a deep-crimson or more commonly brownish-red color, and is often softened and covered with a diphtheritic exudation, but is rarely ulcerated. Perforation is exceedingly uncommon. The mucous membrane of the upper part of the small intestine, and sometimes of the whole of it, is in a condition similar to that of the stomach. In some cases the lesions very closely resemble those of cholera, as was first pointed out by Professor Virchow (*Virchow's Archiv*, Bd. xlvii.). In the microscopic examination of a cadaver whose bowels were filled with a "rice-water" fluid, that observer found in the intestinal contents epithelial flakes, and the fungus described by Klebs as peculiar to, and, indeed, the cause of, cholera. The epithelial cells of the mucous membrane were choked with granules, and many of them in an advanced stage of fatty degeneration; the interstitial tissue was full of large round granulated cells; the solitary glands and Peyor's patches were very much swollen. These facts have been confirmed by Dr. Hoffmann (*Virchow's Archiv*, Bd. l. p. 456). The gastro-intestinal lesions produced by arsenic are not due solely or largely to its immediate local effect, since they occur equally when the animal is killed by injection of the poison into a vein. The local influence of the drug is, however, probably not altogether lost, since Unterberger (*loc. cit.*) found that a larger dose was required to kill an animal by venous injection than by exhibition by the mouth. Curious and at present unexplainable anomalies occur in the distribution of the gastro-intestinal inflammation, and autopsies have been reported in which the stomach has altogether escaped.

There is usually in acute arsenical poisoning a wide-spread granular or fatty degeneration of the tissues. M. Karajan (*Tardieu, Sur l'Empoisonnement*, p. 335) reports a case, which had been mistaken during life for acute atrophy of the liver; Fr. Grohl and Fr. Mosler (*Virchow's Archiv*, Bd. xxxiv. p. 213) one in which they found fatty or granular metamorphosis of the glands and epithelium of the stomach and intestines, of the cardiac muscle, of the diaphragm, of the cortical portions of the kidney, and, to a slight extent, of some of the voluntary muscles; Dr. J. I. Pinkham (*Boston Med. and Surg. Journ.*, 1878, 358) one in which the liver, kidneys, and epithelial lining of the peptic glands were almost destroyed; similar lesions have also been reported by M. V. Cornil (*Soc. Méd. des Hôp. de Paris*, xvii. 379) and by Dr. Féréal (*Ibid.*, p. 321).

The absolute demonstration of the degeneration produced by arsenic was, however, made by Dr. Salkowsky (*Virchow's Archiv*, Bd. xxxiv. p. 77), of Moscow, who was also the first to point it out. In his numerous experiments upon rabbits he found that when the animals were poisoned by a small dose of arsenic, so as to live from three to six days, the liver was much enlarged and very fatty,—indeed, contained more fat than the “phosphorus-liver.”* On microscopical examination, the cells on the exterior of each acinus were seen to be natural; those in the centre in the most advanced stages of degeneration. The kidneys were similarly affected,—their tubes choked up with fat globules, their epithelium almost completely destroyed. The muscles of the heart and diaphragm were almost equally compromised. Dr. Salkowsky also noted that early in both arsenical and antimonial poisoning the glycogenic function of the liver is abolished.† Podowysotszki finds that the first change produced by overwhelming doses of arsenic consists of the formation of necrotic foci in the liver (*St. Petersburg Wochenschr.*, 1888). O. Silbermann believes that during life thrombi form in various portions of the body (*Archiv Path. Anat.*, cxvii. For further discussion, see Ziegler, *Beiträge Path. Anat.*, Bd. ii.; also, M. Wolkow, *Archiv f. Path. Anat. u. Phys.*, cxxvii., 1892). In frogs poisoned with arsenic the epidermis peels off from the derm, as was first noted by Ringer and Murrell, and Emily A. Nunn has found that the influence of the poison is first manifested in the under portion of the epidermis, the degeneration progressing from the derm outward (*Journal of Physiology*, i. 247).

In some cases of arsenical poisoning yellow patches, believed to be due to the formation of arsenical sulphides, have been noted on the mucous membrane of the stomach and intestines. Similar yellow deposits were found by Chunilal Bose (*Indian Medical Gazette*, xxvii., 1892) on the endocardium. It is probable that in these cases the sulphide is formed before or after death by the aid of putrefactive gases.

As arsenic is never used in medicine for an acute effect, the chief interest to the therapeutist centres around its physiological action when given in small doses; yet it seems necessary here to take cognizance of the physiological action of large amounts of the poison.‡

* According to T. Araki (*Zeitschrift f. Physiol. Chemie*, xvii., 1892), arsenical poisoning is related to phosphorus-poisoning, not only in the occurrence of fatty degeneration of the liver, but also of the appearance of lactic acid in the urine.

† For a spectroscopic study of the effect of arsenic upon the coloring matter of the blood, see *Centralblatt*, 1888, p. 609. It is interesting here to note that arsenic, antimony, phosphorus, and ammonia act very similarly, if not identically, upon the blood.

‡ The theory of Binz and Schultz, that arsenous acid acts by taking from protoplasm oxygen, so as to be converted into arsenic acid, and afterwards yields up this oxygen to oxidize the protoplasm, and then repeats the process, seems to me so ill supported that the reader is regard to it is simply referred to *Arch. f. Exper. Path. u. Pharm.*, xi. 213, xiv. 249; also *Brit. Med. Journ.*, 1892, ii. 1135. Dogiel's theory, that arsenic unites chemically with the albuminous principle, is more probable. See *Trans. International Congress*, 1884, i. p. 134.

Nervous and Muscular Systems.—The symptoms of arsenical poisoning in man show that the drug has a marked influence upon the nervous system. Dr. W. Sklarek, of Berlin (*Reichert's Archiv*, 1866), has found that the arseniates of potassium and of sodium had exactly the same effect as arsenic itself upon frogs. Within five minutes after the injection of one-fourth to two c.c. of a two-per-cent. solution of arsenious acid, or of the arseniate of sodium or of potassium, all voluntary movement ceased in the frog, although when the animal was laid upon his back he struggled very actively to recover his position. At this time, however, all sensibility to chemical and mechanical irritants was lost, cutting, burning, or corroding failing to elicit any response. That the motor system was not at fault was shown by the active movements when the frog was placed upon his back, as well as by the results of electrical stimulation of the nerves. The paralysis or quietness must have been due to an abolition of sensation. That this was spinal, and not peripheral, was proved by the circumstance that tying the iliac artery upon one side before the administration of the poison had no effect in preserving sensibility in the protected leg. The only explanation of the struggles of the frog to recover his position after poisoning is to be found in his having been influenced through vision, or else in the theory that the muscular sense is distinct from that of common sensibility and is not affected by arsenic. The researches of Ringer and Murrell (*Journal of Physiology*, i. 217) upon frogs have given very different results from those just described, they finding that the symptoms of poisoning came only after the lapse of some hours, and that paralysis of voluntary motion preceded that of sensation and reflex action. Drs. Ringer and Murrell suggest that these differences of result depend upon the time of year at which the frog was experimented on. There is accord between the experimenters in regard to the cause of the final paralysis, all finding that it is produced by a direct action of the arsenic upon the nerve-centres. Ringer and Murrell have also shown, however, that the nerves and muscles do not entirely escape the poison, which seems to be more or less toxic to all highly-organized tissues.

Circulation.—Upon the heart of the frog Dr. Sklarek found that arsenic exerts a very powerful influence, lessening the rapidity and force of the beat, and finally arresting the contraction. That this cardiac action of arsenic is direct was shown by the exact similarity of the phenomena produced by the application of arsenic to the heart cut out of the body. The arrest was never instantaneous, but always preceded by slowing of the beat; and after movement had ceased, galvanic or mechanical irritation caused imperfect systolic movements. In no case did Dr. Sklarek observe any signs of functional excitement preceding the development of the cardiac or motor paralysis.

Dr. Sklarek also found that in arsenical poisoning in the cat there is great reduction in the force and frequency of the heart's pulsations. Recently the effect of the poison upon the circulation of mammals has

been elaborately investigated by Dr. S. Unterberger (*Archiv f. Exper. Path. u. Pharm.*, Bd. ii.). Like Cunza, he found that in arsenical poisoning the heart persists in its movements after the cessation of respiration. Immediately after an injection of the poison in cats and dogs, both the pulse-rate and the arterial pressure fall enormously, and if the dose has been sufficient they never recover themselves. Dr. Unterberger did not make out the cause of the fall of the pulse-rate, but the experiments of Sklarek, already mentioned, indicate that it is due to a direct action on the heart.

The depression of the arterial pressure was shown by Unterberger to be largely due to vaso-motor paralysis, for in an animal under the influence of the poison neither galvanization of a sensory nerve nor of the vaso-motor centre in the upper cord had any influence upon the force of the blood-current. Galvanization of the splanchnics had no effect upon the arterial pressure,—apparently showing that the vaso-motor palsy was peripheral; but Dr. Unterberger found, to his astonishment, that stimulation of the cervical sympathetics had the usual effect upon the vessels of the rabbit's ear. Supposing these observations to be correct, there are only two seemingly possible methods of reconciling them: either the drug acts upon the peripheral vaso-motor nerves in the abdomen and not upon the same nerves in the neck, or else there is during arsenical poisoning such depression of the power of the cardiac muscle that narrowing of the blood-path does not have the usual effect. Dr. Unterberger found that compression of the abdominal aorta was followed by a great rise of pressure, and therefore he believes that the heart in arsenical poisoning has not lost its power. Some complicated transfusion experiments which he made indicated differently, so that while his proposition that arsenic paralyzes the peripheral vaso-motor nerves of the abdomen and not those of the head may be considered probable, it certainly is not proved. It would be a very easy matter to decide the question by dividing the splanchnic nerves in a poisoned animal: if the reduction of the arterial pressure be really due to an abdominal vaso-motor paresis, section of the splanchnic should have no effect on it. There appears to be no doubt that the cardiac muscle is more or less weakened by the poison.

Action of Small Doses.—Minute quantities of arsenic may be given for a long time without producing any perceptible effect, unless it be a sharpening of the appetite, due to the local action on the stomach. When the dose is increased, more active manifestations of gastric irritation may appear, such as loss of appetite, nausea, abdominal pain or uneasiness, diarrhoea, and perhaps sympathetic headache. By the use of frequent small doses these symptoms may be generally avoided, and what may be termed the constitutional action of arsenic be obtained. The first sign of this is generally a puffiness about the eyes, at first visible only in the early mornings, but soon increasing into decided oedema, which after a time may lose its local character and the patient

be involved in general anasarca. This anasarca, as was, I believe, first pointed out by Dr. S. Weir Mitchell (*New York Medical Journal*, vol. i.), may or may not be preceded or accompanied by the presence of albumen and of tube-casts in the urine. Beyond the production of the symptoms spoken of, arsenic should never be employed in medicine.

Unfortunately, owing to the frequent use of the metal in the arts, chronic arsenical poisoning is by no means uncommon. Although the symptoms vary a good deal and may be very obscure, yet in almost every case they are such as should at once awaken suspicion. They were summed up by the late Professor Taylor as follows: "Dryness and irritation of the throat, irritation of the mucous membranes of the eyes and nostrils, dry cough, languor, headache, loss of appetite, nausea, colicky pains, numbness, cramp, irritability of the bowels, attended with mucous discharges, great prostration of strength, a feverish condition, and wasting of the body." It is very evident that the symptoms of irritation of the respiratory mucous membrane are largely, if not entirely, due to the local action of the arsenic, since the poison finds access to the system through the respiratory organs. The constitutional troubles most uniformly present in these cases are weakness and emaciation, often accompanied by more decided nervous manifestations than the picture drawn by Dr. Taylor would suggest: great depression of spirits and irritability of disposition, sleeplessness, giddiness, tinnitus aurium, failure of memory, cerebral neurasthenia, headache with a feeling of constriction in the forehead, numbness in the extremities, muscular tremors or stiffness, vertigo, and even convulsions and paralysis, are very common. (See *Deutsche Klinik*, 1874, No. 31; *Schmidt's Jahrb.*, Bd. clxv. p. 233; *Deutsch. Archiv Klin. Med.*, Bd. xlv., 1889; *Boston Med. and Surg. Journ.*, cxviii., cxix., cxx., cxxi., cxxii.)

Dr. Kirchgässer, as the result of very large experience, asserts that the most characteristic phenomena of chronic arsenicism are a brown pigment-deposit in the skin of the face, inflammatory affection of the eyelids, and the disturbances of sensibility and motion, which affect most frequently the lower extremities, together with scalding during urination. Out of eight cases, he found arsenic in the urine in six (*Berlin. Centralblatt*, p. 574, 1868). The diagnosis of chronic arsenical poisoning is often very difficult and obscure. Sometimes eruptions upon the skin, with laryngo-bronchial catarrh, swollen finger-joints, emaciation, and other disturbances of the general nutrition, constitute the main features of the case. So closely may chronic arsenical poisoning simulate various diseases that the practitioner can only avoid being misled by remembering that peripheral neuritis is almost always due to the presence of some poison, and emaciation without local disease and with atypical symptoms is usually either toxic or diathetic. Suspicion having been aroused, the urine should be examined for arsenic.

Seemingly opposed to this common experience is the asserted "arsenic-eating" of the peasants of Styria. It is stated by some that the

arsenic is taken by the young girls to beautify their complexion and to enhance their charms; by others, that the object sought to be attained is protection against arsenical fumes by those engaged in the manufacture of the metal, and the increase of the powers of endurance and of the "wind" in huntsmen and others who do a great deal of mountain-climbing. The habit is said not to be detrimental to life. Indeed, the toxiphagi are asserted to be remarkably long-lived people. In regard to the dose, three grains are said to be taken as a commencement, and to be increased to thirty! Originally affirmed by Vogt (*Lehrbuch der Pharmacodynamik*, Aufl. iii. Bd. i.), the existence of this practice has been especially asserted by Tschudi, and more recently by Chas. Heisch (*Pharm. Journ. Trans.*, 1859 and 1860, vol. i. p. 556).

Notwithstanding the assertion of Heisch, the existence of the practice was not credited (see *British and Foreign Med.-Chir. Review*, vol. xxix. p. 144), but in 1864 Dr. C. MacLagan (*Edinb. Med. Journ.*, 1864, p. 203) visited Styria, saw several arsenic-eaters, administered to one of them five grains of the substance at a dose without ill effects, and found the poison in the urine. He also analyzed the material which the men habitually took, and found it to be arsenic.

An unsigned (editorial?) communication in the *Edinb. Med. and Surg. Journ.* (1871, vol. xvi. p. 569) further asserts that a royal commission has examined into the subject, and that their report indicates that the practice exists, but that it has been grossly exaggerated. They affirm that arsenic-eating is practised chiefly in the northern and northwestern parts of Styria; that the white arsenic is preferred, the yellow commercial article being sometimes taken, the native red arsenic, or orpiment, very rarely; that the commencing dose is about 0.22 grain, which is very slowly increased to 0.62 grain avoirdupois. The "ratsbane-eaters" almost all belong to the lower classes, and are said to be generally strong and healthy persons, courageous, pugnacious, and of strong sexual disposition. These statements are in accord with those of Dr. MacLagan, and must, I think, be accepted as true. Dr. MacLagan also says that in one case of suspected poisoning in Styria the prisoner was acquitted on the ground that the deceased was an arsenic-eater. (See also *Wiener Klin. Wochens.*, v., 1892.)

Of especial interest in connection with arsenic-eating is the verity or non-verity of the asserted effect of the drug upon tissue-changes. Schmidt and Stürzwage believe that it has such action in a very marked degree, because in their experiments upon rabbits they found a decided diminution in the excretion of carbonic acid and of urea during the use of minute doses of the poison. Fokker (*Schmidt's Jahrb.*, clviii. 13), however, was unable to perceive in three experiments that daily doses of from .15 to .075 grain of arsenic to a dog had any effect upon the elimination of urea, and Kossell and Gaethgens, in two experiments, have noted a very decided increase of the elimination of urea produced by toxic doses of arsenic in the dog (*Arch. f. Exper. Pathol. u. Pharm.*,

Bd. v. p. 133, also *Centralbl. f. Med. Wissen.*, 1875, 530; 1876, 833). The recent experiments of Chittenden and Cummins (*Stud. Labor. Physiol. Chem. Yale Univ.*, vol. ii.) are in accord with the early results of Stürz-
wage, as they found that in the case of rabbits arsenious acid has a tendency to diminish the elimination of carbonic acid. The evidence which we have at present is not sufficient to warrant a positive opinion, but it indicates that small doses of arsenic check tissue-change and decrease nitrogenous elimination, while large toxic doses have the opposite effect.

When arsenic is administered in small repeated doses, it may act as a tonic, by slightly irritating the stomach and thereby provoking an appetite; and in certain cachexias it increases the muscular strength and the general vigor. The history of arsenic-eating indicates that the drug has some positive tonic influence over nutrition; and although the amelioration, the increase of strength and blood, by its use in cachexias may be due to an indirect action of the drug,—to a removal or overcoming of the morbid agent of the disease, and a consequent allowing of the recuperative powers of the system to assert themselves,—there is much reason for believing that it does act as a direct stimulant to nutrition. All that we know of the effect of arsenic upon the system throws only enough light on its therapeutic action to enable us to class it as an alterative,—a modifier and often an improver of nutrition.

Elimination.—The rapidity of the absorption of arsenic varies greatly with the form in which it is ingested, liquid preparations, such as Fowler's solution, yielding the drug with great rapidity. It has generally been believed that the elimination takes place with exceptional rapidity; thus, MM. Flandin and Danger (Husemann, *Toxicologie*, p. 823) failed, three days after the last dose, to detect arsenic in the bodies of animals to which fifteen grains had been given daily; and in a child killed in two days by an arsenical pigment, none of the metal could be found in the body (*British and Foreign Med.-Chir. Review*, 1870, vol. xlv.). In the great majority of instances, however, there is no trouble in finding arsenic in the bodies of those poisoned by it, and Steinbrückner reports a case in which it was found in the remnants of a corpse that had been buried for twenty-two years (*Berlin. Centralblatt*, 1868, p. 160). Further, it would appear that the failure to find arsenic has often depended upon the lack of delicacy in the chemical operations. Using the chemical method devised by Professor Chas. R. Sanger, Professor Edw. S. Wood has been able to detect arsenic in the urine ninety-three days after the taking of a single toxic dose, and from sixty to eighty days after mild courses of Fowler's solution (*Boston Med. and Surg. Journ.*, cxxviii., 1893). The principal channel of escape is the kidneys, but elimination also takes place through the mucous membrane of the alimentary canal, through the skin, and even in the saliva and tears. M. G. Bouchet and Lewald in independent researches found arsenic in notable quantities in the milk of nursing women to whom it

had been given. (See *American Practitioner*, 1887.) Unterberger has detected it in the alimentary canal of animals poisoned by injection into the vein. M. Chatin has found it in the serosity of a blister, Bergeron and Lemaitre in the sweat (*British and Foreign Med.-Chir. Review*, vol. xlviii., 1871), and Taylor (*Guy's Hospital Rep.*, vol. x. 3d series, 1864, p. 227) in the contents of the stomach of a child poisoned by its application to the scalp.*

Especially in connection with the therapeutic use of arsenic in malarial fever, some interest attaches to the effect of the drug upon the lower organisms and fermentations. The subject has been partially investigated by Johannsohn (*Arch. f. Exper. Path. u. Pharm.*, Bd. ii. p. 106), who concludes that the poison produces a peculiar degeneration of the yeast-plant, but actually increases the production of bacteria in yeast. When small amounts of arsenic were added to yeast and syrup, the fermentative process was at first very much checked, but not absolutely prevented. After a time the process went on faster again. In urine Johannsohn found that the poison hindered the production of *Micrococcus urea*, but actually favored that of other fungi. In the lactic fermentation the growth of the peculiar fungi was checked, while that of *Mucor mucedo* was favored. The fact that arsenic acts slowly upon the yeast has been confirmed by Schaefer and Boehm (*Arbeiten Physiol. Inst. Würzburger Hochschule*, 1873, p. 173). Both Johannsohn and Schaefer and Boehm have found that arsenic exerts no influence upon non-organized ferments, either vegetable or animal, such as amygdalin, pepsin, pancreatin, etc.

THERAPEUTICS.—Our knowledge of the value of arsenic in disease rests solely upon clinical observation, which has abundantly established its use in certain very diverse affections. Chief among these is *chronic malarial dyscrasia*. No one would at present think of employing it in *acute remittent fever*, or even in *acute intermittent*, unless under very peculiar circumstances. It is in those cases which have resisted quinine, in which the paroxysms have become irregular, returning at long or irregular intervals, and in which the anæmia and the general nutritive disturbance are even more prominent than the febrile disorder, that arsenic is especially valuable. In these cases it should be administered with sufficient boldness, very generally in conjunction with iron. Professor George B. Wood recommends that the first doses should be as large as the system will endure, so as to make a decided impression at once. When the ague-paroxysms are frequent, it is perhaps well to employ this plan; but when it is rather the cachexia than the active disorder that is to be combated, it is preferable to commence with small doses and to increase them until some constitutional symptom

* Various observers have endeavored to determine which tissues contain most arsenic after death from the poison, with varying results. Consult *Arch. de Physiol. Norm. et Path.*, 1875, li. 553; *Chem. Centralblatt*, 1879, 602; *Arch. f. Exper. Path. u. Pharm.*, xlii. 257; *The Chemist and Druggist*, xxi., 1879, 381; *Comptes-Rendus*, 1879, lxxviii. 1212.

is produced. In ordinary *intermittents*, after the paroxysms have been broken up by quinine it is very well to place the patient upon a preparation of arsenic and iron, as a prophylactic against their return. When, in ordinary *intermittent fever*, for any cause quinine cannot be administered, arsenic may be employed. In these cases, as already intimated, the first doses should be large, so as to make an immediate impression; from five to ten minims of Fowler's solution, properly diluted, may be given every two or three hours until some decided symptom is produced. When the stomach refuses the remedy, it has been recommended by Boudin to give it by the rectum, which he affirms will often bear even a grain of the acid. Not more than a third of this amount should, however, be used as a commencing dose. In *malarial intermittent neuralgia*, arsenic may be employed as a very useful adjuvant to the antiperiodic alkaloids. Dr. K. M. Downie calls attention (*Indian Medical Journal*, 1872) to the value of arsenic as a *prophylactic* against malaria. His trials were not numerous enough to be conclusive, but so far as they go they indicate that arsenic is even superior to quinine. Recently attention has been drawn to the great value of arsenic in *lymphatic tumors*, especially in the affection known as malignant *lymphoma* (*Wien. Med. Wochenschrift*, 1871; *Arch. f. Klin. Chir.*, xviii.; *Stricker's Jahrb.*, 1877). Advantage is said to be sometimes derived from injections of the remedy into the growth.

Having had very little experience myself in the use of arsenic in *skin-disease*, Dr. Louis A. Duhring, Professor of Dermatology in the University Hospital, has kindly furnished me with the following:

"As is well known, arsenic has long been used and held in high esteem as a remedy in the treatment of cutaneous diseases. It is proper to state, however, that at the present day there exists a great diversity of opinion concerning its actual value as a therapeutic agent against this class of diseases. Certain dermatologists claim to derive marked good from its employment in quite a large number of affections, while others of equal experience are inclined to place but little reliance upon its curative powers. Without entering at all into this discussion, it may be unhesitatingly said that it is a remedy of real worth and service in several very important cutaneous diseases, and that it may be combined with other remedies and used with good result in certain other diseases of the skin, acting in these cases as a general tonic. It is the dermatologist's most valuable internal remedy in a large number of cases. But it must be skilfully employed, and the cases, moreover, must be selected, if we would expect satisfactory results. To say that arsenic is of use in diseases of the skin viewed collectively, is an assertion so vague as to be of no practical value. Not only is it necessary to specify the disease, but it is even important to designate the particular stage if we would employ the remedy successfully.

"Arsenic exerts its influence chiefly upon the epidermis. Hence it is found that diseases affecting the more superficial strata of the skin are

most amenable to its influence. It possesses little or no effect upon the diseases which have their seat in the deeper structures.

"Its action upon the skin is slow, weeks and months being requisite to produce the desired result. Improvement once obtained, it is usually expedient to allow the patient to continue the use of the remedy for some weeks after all symptoms of the disease have disappeared.

"Arsenic should never be employed in the acute, inflammatory stage of any disease of the skin. It should not be prescribed when there is great heat, burning, intense itching, or rapid cell-change. It not only is of no benefit at this stage, but is in most cases positively injurious, tending to augment the activity of the morbid process. It stimulates the rete into action when rest is most needed. Its administration should be withheld until the acute symptoms have subsided.

"Of many of the dissimilar diseases in which arsenic has been employed, both with and without reputed success, no mention need here be made. It will suffice for the purpose in hand to refer to those affections which it is generally conceded are more or less favorably influenced. It is unquestionably of great value in *psoriasis*. But it is not of benefit in every case, nor should it be prescribed for all forms, or in all stages, of this disease. When the process is very active, attended with intense hyperæmia, arsenic, as a rule, only aggravates the inflammatory condition. The more active the cell-proliferation, the less probability is there of its being of benefit. On the other hand, the more indolent and sluggish the disease, the greater the chances for improvement. It should be withheld until the process has fairly settled in its career. In cases of *psoriasis* of long standing, which manifest little disposition to undergo change, it is particularly useful.

"It is of considerable service in certain varieties of *eczema*, especially in the chronic squamous and papular varieties; also where the elementary lesions are but ill defined; and, finally, where the disease is unusually superficially seated, and where there is only slight infiltration of the skin. Certain forms of persistent localized papular and vesicular *eczema*, having a marked tendency to recur, as, for example, of the fingers, also often yield readily to arsenic. It should, of course, be avoided in acute *eczema*.

"*Pemphigus* is decidedly influenced, and often permanently relieved, by its use. It is our most reliable remedy for this disease. Here, as in other conditions, the older the process the more likely are we to obtain favorable results. In *lichen planus* and in *lichen ruber* it is employed with great advantage. Prescribed in minute doses, as a tonic, it may sometimes be given with benefit in chronic *urticaria*.

"It may prove of value in certain varieties of *acne*. Before prescribing it, however, the digestive tract should be carefully looked into, and, if disordered in the least degree, it should first be rectified. The same remark holds good for its use in all diseases of the skin. Taken

for a considerable time, several months, it sometimes exerts an influence upon the small pustular and papular forms of aene, and especially in those cases where there is debility or anæmia.

"The two preparations of arsenic which it is, as a rule, advisable to employ are *arsenous acid* and *liquor potassii arsenitis*. The latter will be found the more desirable form for ordinary use. Arsenious acid is given in pill form, with sugar of milk, or combined with a grain each of black pepper and powdered liquorice, constituting the compound known as the *Asiatic pill*, which may be prescribed in various strengths, suitable to the case. The liquor potassii arsenitis is best given with water or combined with a bitter tincture or infusion; it is also well borne combined with the wine of iron. The average dose suitable to the majority of individuals is three minims. Smaller doses, one or two minims thrice daily, are often demanded, and in many cases are found to be much more beneficial than larger doses. On the other hand, four, six, or eight minims will not infrequently be tolerated, and occasionally even larger doses; but out of a number of patients it will be found that but few can take more than three or four minims for any length of time without derangement of the system. Arsenic should always be taken either with the food or directly afterwards."

In certain nervous affections arsenic acts very favorably, in some unknown way. It is especially in *chorea* that it has acquired a deserved reputation. In this affection iron and other tonics are generally indicated, and may be given consentaneously with the arsenic. It is best, however, to administer the latter separately, as the dose must be steadily increased until oedema or other manifestations betray its decided action. Arsenic has also been recommended in *whooping-cough*, but is at present very rarely, if ever, used. In ordinary *non-malarial neuralgia* it may be tried, and is sometimes serviceable; in simple *gastralgia*, or *gastric neuralgia*, it has been especially recommended.

Arsenic is employed sometimes with advantage in *asthma*, and may be given by the stomach, but is perhaps more useful when inhaled. The following formula has been long used in the Philadelphia Hospital. The prepared paper is rolled into cigarettes, one of which is smoked two or three times a day, until relief is afforded or some giddiness produced:

CHARTA ARSENICALIS COMPOSITA (*Compound Arsenical Paper*). R—Belladonnæ fol., gr. xvi; Hyoscyami fol., Stramonii fol., ãã gr. xlviii; Extr. opii, gr. iv; Tubaci, gr. lxxx; Aquæ, Oj; M., ft. sol. et add. Potas. nit., gr. clx; Potas. arsenit., gr. cccxx. Saturate bibulous paper and dry for use.

Arsenic is of value in those forms of *chronic rheumatism* in which iodide of potassium is commonly employed. It is often advantageous to alternate, administering one of these alteratives for three or four weeks, and then the other for the same length of time. In *rheumatic gout*, or *rheumatoid arthritis*, it has been highly extolled, but in my

Experience has furnished no better results than other remedies. It should, however, always be tried in this most obstinate disorder.

Sometimes in acute, more frequently in the chronic arsenical poisoning, or as the result of a long-continued medicinal use of the drug, certain disorders of the skin appear. Of these, herpes zoster seems to be the most frequent; it probably is the result of an arsenical neuritis. As stated in the elaborate article of Dr. C. Rasch (*Ann. Dermat. et Syph.*, tome iv.), there have been observed as produced by arsenic, first, pigmentation;* second, erythematous and desquamatic eruptions; third, urticaria and subcutaneous oedema; fourth, vesicular eruption; fifth, bullæ; sixth, papules; seventh, pustules and ulcers; eighth, purpura; ninth, shedding of the hair and nails; tenth, keratosis. (See also article by O. Juliusburger, *Vierteljahr. f. Dermatol.*, Wien., xi. 97.)

TOXICOLOGY.—Sufficient has already been said concerning the symptoms of both acute and chronic arsenical poisoning. No mention has, however, been made of the peculiar local affections produced in the hands of those artisans who work with the preparations of arsenic. Ulcers about the roots of the nails are generally the first trouble in these cases, but after a time eczematous or papular eruptions appear, and even subdermal erysipelatous inflammation is developed. Very commonly to these local symptoms are added, after a time, the usual phenomena of chronic arsenical poisoning.

In the arts, preparations of arsenic are largely used as pigments;† and, excepting the manufacturers of arsenic, it is almost exclusively those who are accidentally exposed to the deleterious influence of these pigments that suffer from chronic arsenical poisoning. The poisonous colors are of various hues, and, being very cheap, and remarkable for their purity of tone and their permanence under exposure to light, are much used by paper-makers. *Scheele's Green*—the arsenite of copper—contains fifty-five per cent., by weight, of arsenious acid; and *Schweinfurt Green*—the aceto-arsenite—fifty-eight per cent. Paper coated with them has been largely used not only as hangings, but even as wrappings for confectionery and other edibles. The arsenical dyes

* For elaborate microscopic study of arsenical melanosis, see Hugo Müller, Berlin Thesis, 1892.

† For an excellent report upon this subject, see *Report of the State Board of Health of Massachusetts*, Jan. 1872, where it is stated that from five hundred to seven hundred tons of arsenical pigment were manufactured in 1862 in England alone. Fatal chronic arsenical poisoning from working in aniline dyes is reported in *Stricker's Jahrb.*, 1877, 591. In recent literature the most important paper is that of Professor F. C. Shattuck (*Med. News*, lxii., 1893), who reports a number of cases in which the symptoms have been gastro-intestinal irritation, anæmia, dermatitis, redness of the conjunctiva, puffiness under the eyes, headache, inflammation of the upper air passages, albuminuria with casts and blood, and peripheral neuritis. The number of cases detected of chronic arsenical poisoning in and about Boston, contrasted with the rest of the world, is something remarkable, and is scarcely to be accounted for by the alleged superior acuteness of the Boston physicians. A further difficulty of the subject is that arsenic has been detected in the urine of a number of Boston people without the presence of any symptoms of ill health. Can there be some local focus?

are not all green, but may be in almost any hue; they are largely due to the use of arsenic in the manufacture of magenta and other aniline colors. Professor E. S. Wood, of Harvard (*Boston Med. and Surg. Journ.*, cxix., 1888), has shown that in different parcels of the same goods one will contain arsenic and the other not, because the aniline dyes are sometimes contaminated with arsenic and are sometimes free from it. These poisonous colors are by no means confined to wall-paper. Sweetmeats have been colored with them; pasteboard boxes, artificial flowers, tarlatan dresses, India muslins, cretonnes, walls of dwellings, shelves of groceries, toys of children, and various other articles, have been made the vehicles of death, so that hundreds of cases of poisoning have resulted from the use of these pigments, which ought to be banished by the strictest laws. In most cases it is probably the minute dust, which is separated mechanically and diffused through the room, that produces the fatal result; but poisoning has occurred when the arsenical paper was covered over with another paper. Dr. Hambors has made elaborate chemical researches upon the air of these apartments, and believes that he has demonstrated that some arsenic escapes in the form of arsoniuretted hydrogen. Not rarely the poison has been taken directly into the stomach, especially by children.

The time at which death occurs, as well as the fatal dose of arsenic, varies very much. Death usually results in from eighteen hours to three days; but Taylor reports a case in which it occurred with tetanic symptoms in twenty minutes, and life has been protracted until the sixteenth or even the twentieth day. Dr. W. C. Jackson (*Amer. Journ. Med. Sci.*, July, 1858) records a case of recovery, under the early use of emetics, after an estimated dose of two ounces had been taken; and Dr. E. D. Mackenzie gives an account (*Indian Med. Gaz.*, 1872) of a man who swallowed an unknown quantity of arsenic in lumps, and received no treatment for sixteen hours, yet recovered after passing per anum one hundred and five grains of arsenic in two masses. On the other hand, death has resulted from the use of very small amounts. Dr. Taylor asserts that the smallest fatal dose hitherto recorded is two grains. Dr. Lachèse (*Ann. d'Hyg. et de Méd. Légale*, 1834, 1e sér., xvii.) affirms that six milligrammes (0.09 gr.) will produce decided but not serious symptoms, and that from one to three centigrammes (0.15 to 0.462 gr.) are poisonous, and from five to ten centigrammes (0.77 to 1.54 gr.) fatal. Tardieu places the minimum lethal dose at from ten to fifteen centigrammes (1.54 to 2.31 gr.). The escapes from death after the ingestion of large amounts of arsenic have, without doubt, depended upon its being, as in the cases above narrated, in an insoluble form. The effects of the arsenical solutions, such as Fowler's, are more rapid and severe than those of the solid drug.

As arsenic in large doses generally induces vomiting, it is very rarely necessary in poisoning to evacuate the stomach by artificial means. If free emesis, however, have not occurred, a prompt emetic, such as m

tard or sulphate of zinc, should be at once exhibited, and very generally the stomach should be well washed out by large draughts of warm water, with salt, if necessary for the return of the water. With the emetic, or sooner, if possible, the antidote should be administered. The substance whose antidotal value has been most thoroughly tested and assured by clinical experience is the *freshly-precipitated ferric hydrate*, which forms with arsenous acid a very insoluble compound. The antidote must be freshly prepared, and must be given in great excess: according to the experiments of Messrs. T. and H. Smith, of Edinburgh, at least eight grains of the iron being required for the conversion of one grain of the arsenious acid. In practice, any of the sesqui solutions of iron—that of the chloride being generally preferred, as most readily procured—should be neutralized by carbonate of sodium or preferably by magnesia, and a portion of the precipitate given at once, stirred up in hot water. The remainder of the antidote, having been hastily washed by emptying it on to a piece of muslin or a filter, pouring water on it and allowing it to drain, should be administered very freely,—indeed, indefinitely, as it is entirely harmless. H. Kohler, of Halle (*Brit. and For. Med.-Chir. Rev.*, 1870, vol. xlv. p. 538), has made a very elaborate series of chemical, physiological, and clinical experiments upon the comparative antidotal values of the *saccharated ferric oxide* and the *freshly-precipitated ferric hydrate*. His results indicate that the former preparation is the better; but, as the efficiency of the hydrate has been so frequently proved at the bedside, further testimony is desirable before it is superseded, especially since the other ferric preparation is not officinal with us, and is not so readily prepared on the spur of the moment as its fellow. *Dialyzed iron* has been used with very good results, but it is much better to precipitate it, just before administration, with a small amount of ammonia or other alkali. *Magnesia*, freshly calcined or freshly precipitated from a solution of its salts, is an antidote of some avail in arsenical poisoning, but is decidedly less efficient than the oxide of iron.

Under the name of *Ferri Oxidum Hydratum cum Magnesia*, the arsenical antidote of the German Pharmacopœia was recognized at the 1880 revision of the U. S. Pharmacopœia. It is made by precipitating the solution of ferric sulphate by magnesia, and is probably the best of the antidotes. In emergencies, Monsel's solution, tincture of the ferric chloride of iron, or other of the ferric preparations may be substituted for the tersulphate.

After the emetic has acted in a case of arsenical poisoning, and while the antidote is being given, castor oil should be administered, for the purpose of expelling the poison from the bowels. The further treatment should be directed by general principles,—demulcent drinks, opium, stimulants, dry external heat, and rubbing being employed as called for by the symptoms. When there is a tendency to suppression of urine, very large draughts of water containing sweet

spirit of nitre should be given as frequently as the stomach will bear them.

The chief indications in *chronic arsenical poisoning* are to remove the patient from the exposure and to treat symptoms as they arise. Although I do not know of any clinical records bearing upon the subject, it might be well to exhibit the iodide of potassium, in the hope of hastening the elimination of the poison.

ADMINISTRATION.—The commencing dose of arsenic is one-twentieth of a grain, which should be given in pill *after* meals, and be slowly increased until a perceptible influence, or the desired therapeutic effect, is obtained. In many cases (chorea, lymphoma, intermittent fevers, etc.) it is necessary to push the remedy until decided evidences of poisoning are secured: in this case a liquid preparation should be selected. The following are the official preparations of arsenic:

Liquor Potassii Arsenitis—*Solution of Potassium Arsenite*.—*Fowler's Solution* contains four and a half grains of arsenous acid to the ounce, is nearly colorless, odorless, with a very faint taste of the compound spirit of lavender, which is in it. It is an excellent preparation. The average commencing dose is five drops in a wineglassful of water after meals, to be increased and used with the same precautions as arsenic.

Sodii Arsenas—*Sodium Arsenate*.—This salt occurs in transparent, slightly efflorescent, soluble crystals, and is solely used in making the *Liquor Sodii Arsenatis*. The *Solution of Sodium Arsenate* (gr. 4.5 to ℥i) may be used instead of *Fowler's Solution*, in similar doses.

Arseni Iodidum—*Arsenic Iodide*.—This is an orange-red, crystalline solid, wholly soluble in water and entirely volatilized by heat. It has been used as an alterative, and also as an external application in certain diseases of the skin, especially *lupus* and *chronic tubercular affections*. Arsenic iodide enters into *Donovan's Solution*.

Liquor Acidi Arsenosi—*Solution of Arsenous Acid*, is of the same strength, and has the same therapeutic properties, as *Fowler's Solution*. It is, however, a little more irritant than that preparation.

HYDRARGYRUM—MERCURY. U.S.

PHYSIOLOGICAL ACTION.—When a mild, unirritating preparation of mercury is introduced into the system so as to produce constitutional effects, the first symptoms of its action are to be looked for in the mouth. In the mildest degree these symptoms consist of a slight fetor of the breath, and some soreness of the teeth when knocked forcibly together or struck with a key. Mercurial fetor is peculiar, and is generally the first indication that the drug is affecting the system, and is sooner or later accompanied by a disagreeable metallic taste. If the use of the mercury be persisted in, the gums become swollen, soft, and spongy, bleeding on very slight abrasion, and there is a decided increase in the secretion of saliva. Beyond this point the therapist is never justified in carrying the use of the drug. If it be done, the local symp-

toms in the mouth increase in severity, the tumefied gums become inflamed, very vascular, and marked by a dark-red line at the junction of the teeth; the tongue is also swollen, sometimes enormously, protruding from the mouth, whose closure it may entirely prevent; the teeth are loosened in their sockets; the saliva is enormously increased in quantity and altered in quality, forming great, ropy, viscid masses, which pour over the thickened lips; the parotid glands, and even the submaxillary, are very much enlarged, and tender. Sometimes, before salivation occurs, slight systemic erethism, marked by a quickened pulse and general restlessness, may be present; but when the mouth-symptoms are severe, very generally there is a distinct febrile reaction of a low type.

In some cases of mercurialization the stomatitis has been very intense, loss of the teeth, extensive ulceration of the soft parts, and even necrosis of the jaw-bones, have occurred, and death from exhaustion resulted, or the patient struggled through to recovery, seamed and disfigured for life. In these cases passive hemorrhages often recur again and again, and, it may be, contribute largely to a fatal result. During severe ptyalism emaciation goes on rapidly, and seems to affect especially imperfectly organized tissues, so that exudations very generally rapidly disappear. The disturbance of nutrition is further shown in some cases by the occurrence of ulcers upon the extremities. The blood suffers very decidedly, becoming more fluid and watery than normal, and having its power of coagulation impaired. According to the researches of Dr. Wright, its solid constituents are notably diminished, including albumen, fibrin, and the red corpuscles, and it contains a large quantity of a fetid, fatty material. These observations of Wright have been confirmed upon animals by Dr. Wilbouchewitch (*Arch. de Physiol.*, Sept. 1874), and by Dr. I. Hughes Bennett.

Although large doses of mercury lower the general nutrition and destroy the crasis of the blood, it is by no means certain that given in very minute doses it has not tonic properties. In 1869 (*Gaz. des Hôp.*) Liégeois asserted that the subcutaneous injection of very minute doses of quicksilver produces in healthy men an increase of their bodily weight, and in 1876, in two experiments, Dr. E. L. Keyes (*Amer. Journ. Med. Sci.*, Jan. 1876) found that not only was the bodily weight increased, but, as determined by actual count, the number of the red corpuscles was decidedly augmented. Very recently (*Arch. f. Exper. Path. u. Pharm.*, xiii. 317) Dr. Hermann Schlesinger has laboriously experimented upon rabbits and dogs. All other conditions being similar, those rabbits which received the mercury increased in weight a very little more than did those to which mercury was not given, but the augmentation of the red blood-disks was distinctly greater in the mercurialized animals. With dogs the results were more decided, both bodily weight and blood-corpuscles increasing much faster in the animals to which mercury was given. Professor I. Hughes Bennett had

previously obtained results similar to those quoted, and Dr. Schlesinger thinks that it must be considered proved that very minute continuous doses of mercurials tend in the normal animal or man to increase distinctly the weight of the body and the richness of the blood, but that it is scarcely proper to call them tonic, as in his belief they act by hindering oxidation and restricting waste, and not by aiding in reconstruction. In this, however, he seems resting upon theory rather than upon proved fact, and there is much clinical reason for believing that in exceedingly minute doses mercurials in some way benefit nutrition. In some cases of syphilitic anæmia the effect of mercury in increasing the number of red blood-corpuscles is very marked. This effect is, however, to be attributed to the antisiphilitic influence of the remedy rather than to any specific action on the blood-making organs. (For elaborate paper, see Dr. L. Gaillard, *Arch. Gén. de Méd.*, Nov. 1885.)

In some cases of mercurialism, probably as the result of idiosyncrasy, the chief symptoms are severe cutaneous eruptions. The usual fundamental type is said to be a polymorphic erythema, resembling more or less that of scarlet fever, but modified so that in some cases it becomes measles-like or even eczematous. In mild cases the eruption is fugacious, being followed in two or three days by more or less desquamation. In grave cases there is a universal dermatitis, with great swelling of the face and extremities, excessive desquamation, followed, it is asserted, sometimes by thickening and infiltration of the subdermal tissues, excoriation, violent fever, disturbance of the respiration, and death; or, if the patient survive, months of illness. (See M. A. Morel-Lavallée, *Rev. de Méd.*, 1891.)

Sometimes the influence of mercury falls almost exclusively upon the nervous system, and produces a peculiar train of paralytic phenomena. This occurs chiefly, if not exclusively, when it, as vapor, finds entrance to the blood through the lungs, and is most frequently seen in those who work in the metal. It is generally the result of long exposure; but that it may be produced in a very short time is proved by the case, related by Dr. Christison, of two barometer-makers who slept one night in a room containing a pot of mercury upon a stove. One was severely salivated, the other was affected with a shaking palsy which lasted all his life. According to Dr. Sigmond (*Mercury, Blue Pill, and Calomel*, London, 1840), the attack of mercurial palsy, which is sometimes sudden, sometimes gradual, begins with unsteadiness and shaking of the extremities, and of the muscles of the face, which movements interfere with walking, speaking, or chewing; the tremors become frequent, nay, almost constant; "every action is performed by starts." If the exposure be continued, sleeplessness, loss of memory, and death terminate the scene. A peculiar brownish hue of the whole body, and dry skin, generally accompany the disease. In its first attack it may be mistaken for St. Vitus's dance; in its latter stages, for delirium tremens. According to Noël Guéneau de Mussy (*Gaz. des*

Höp., 1868), these two forms are rather distinct varieties than different stages of mercurial tremors. In the latter the affection simulates *paralysis agitans* in its shaking movements; in the former the motions are violent, and occur independently of the will of the patient, even when he is lying quietly in bed. In a case reported by Dr. L. Langer, the electro-contractility of the affected muscles was much heightened (*Wien. Med. Jahrb.*, 1881, 478).

Paralysis from chronic mercurial poisoning is said to be not a rare affection among artisans and miners who are in their daily occupation exposed to contact with the metal or its fumes. The subject has been recently thoroughly discussed by Dr. M. M. Letulle (*Archives de Physiol.*, April, 1887), to whose paper the reader is referred for a collection of recorded cases and for details. In a case reported by Dr. Sigmond, symptoms similar to those of chronic lead-poisoning, including wrist-drop, followed repeated mercurial inunctions. In some cases mercurial paralysis takes the form of multiple palsy, or of a brachial or crural monoplegia, or of an obscure local palsy, as in a case reported by Küsemaul, in which there was aphonia from paralysis of the laryngeal muscles. Almost invariably the loss of motor power is accompanied by an anæsthesia, which may be wide-spread or may be in isolated islets, or may take the form of hemianæsthesia. The loss of sensation is very rarely absolute; simple loss of the thermic sensibility or analgesia may exist alone. Partial anosmia or amblyopia may show that the nerves of special sensation are affected. Neuralgic pains may be the permanent result of a mercurial exposure, and epilepsy and even insanity, most frequently of the melancholic type, are stated to have been so produced. According to Letulle, trophic changes are not common, the paralyzed muscles not undergoing atrophy, and retaining their normal relations to the galvanic and faradic currents. When the thighs are affected the knee-jerk may entirely disappear. Guinon (*Gaz. Méd. de Paris*, 1887) describes violent hysteria following upon chronic mercurial intoxication.

In some cases, exposure to the vapor of mercury, or even its persistent medicinal use, has resulted in the production of a state of the system somewhat resembling scurvy, characterized by great anæmia, emaciation, and general loss of power, with loss of the hair, aching pains in the bones and joints, œdema, fetid breath, diarrhœa, and generally disordered secretions. This is the so-called *mercurial cachexia*.*

As already stated, the salivary glands are especially sensitive to the constitutional effects of mercury, and there is some reason for believing that the pancreas, which resembles them in structure, is also obnoxious to the drug. Thus, in a case related by Dr. Copland, a woman after excessive salivation experienced deep-seated epigastric pain and heat,

* For an interesting paper in regard to mercurialismus in looking-glass makers, see article by Dr. Wollner, *Munch. Med. Wochen.*, July, 1892.

with nausea, thirst, and fever, and voided thin stools containing liquid resembling salivary fluid. At the post-mortem the pancreas was found weighing four ounces, red, congested, and with its duct dilated. In regard to the action of mercury upon the liver, see PURGATIVES.

Little attention has been paid to *local mercurial poisoning*, but Dr. A. W. Foot has reported (*Dublin Journ. Med. Sci.*, 1873) the production of paralysis of the muscles of the hand and forearm by contact with the red iodide of mercury during the rubbing of cattle with a salve containing it. It is asserted that in some peculiar persons the external, and even the internal, use of small amounts of mercurials will produce violent eczema or other skin-eruption (Dr. Alexander, *Vierteljahrs. f. Dermatol. u. Syph.*, xi. 110).

That mercury is absorbed there is abundant proof.* That it is eliminated by the secretions is also very evident. Thus, it has been found in the blood,† in the urine,‡ in the serum of ulcers,§ in the saliva,|| in the feces,¶ in the pus from ulcers, in the seminal fluid,** in the milk of nursing women,††—indeed, in every conceivable secretion and in every tissue. Heller, of Vienna, found it in the aborted foetuses of salivated women, and Mayençon and Bergeret in the urine of a baby whose nurse was taking calomel; and both of these observations have been confirmed by Weillander.

An enormous amount of work has been done to determine how rapidly mercury is eliminated, and whether when given internally it is all thrown out of the system. The result of all this labor seems to me to be to prove that the single dose of mercury does not remain in the system, but that when the drug is administered constantly for a length of time elimination does not keep pace with absorption, so that the mercury accumulates in the tissues. Moreover, the elimination takes place irregularly and intermittently, for reasons that at present cannot be made out. Further, there does not appear to be any limit of time during which stored-up mercury may remain in the body; indeed, all the probabilities point to the possibility of mercury being deposited in

* Dr. S. V. Cleveland (*Chicago Med. Gaz.*, Feb. 20, 1880) believes that mercurials are absorbed, and act in the form of excessively minute globules of the pure metal. Many of his statements are absurdly extravagant; but his observation that when calomel is given to a chicken the metallic globules can be abundantly seen in the blood should be confirmed or overthrown by direct experiments. See also *Chicago Med. Gaz.*, 1880, i. 135.

As N. Popoff found that mercury is capable of producing the same changes in the spinal cord as is arsenic (see p. 513), it is probable that in some cases of mercurial poisoning the symptoms simulate those of poliomyelitis.

the tissues in such form that it is practically inert and exerts no effect upon the system, liable, however, under certain agencies, to be set free and exert its power upon the general nutrition.*

The rate of absorption is of course affected by the method of administration. Wellander (*Ann. Dermatolog.*, vii. 413) has found mercury in the urine fourteen hours after its application to the skin, and one hour after its subcutaneous administration.

The constitutional action of mercury shows that it has relations to the nutrition of the whole body.† The alterations in the blood, the

* In regard to the single dose of mercury the experiments of Mayençon and Bergeret are perhaps the most satisfactory. They found that when one centigramme of corrosive sublimate was given hypodermically to a dog, the urine for the next twenty-four hours contained mercury, afterwards none. When a centigramme was given daily for ten or twelve days, the urine contained mercury for four or five days after the cessation of medication. In their last series of experiments, rabbits received the drug, and were killed at different intervals: in half an hour the metal could be found in all the tissues, the liver and kidneys containing most of it; in four days, or even in a shorter time, mercury given in a single dose was all eliminated, and could not be found in the tissues. This would seem to prove that mercury given in a single dose does not remain in the system.

The evidence in favor of the storing up of mercury in the system is overwhelming. In 1880, Vajda and Paschke (*Ueber den Einfluss Quecksilbers*, Wien) stated that they found the metal in the urine in different cases, six months, one year, two years, and even three, five, six, seven, twelve, and thirteen years after the mercurial course. It may be that in these cases the memories of the patients were at fault, but in the experiments of Mayençon and Bergeret, forty-eight hours after the cessation of a mercurial course, when the urine of one of the investigators was free from the metal, the iodide of potassium was exhibited, and the urine of the next twenty-four hours contained an abundance of mercury, which continued to be present in diminishing quantities for seventy-two hours. Sigismund has found quicksilver in the urine of patients as long as thirteen years after taking the medicine; but Schuster (*Zeitschr. f. Klin. Med.*, vii., 1884) asserts that these patients were habitués of a room in which inunctions were constantly being made, and that under these circumstances there is sufficient diffusion of the mercury to produce a very sensible effect in those breathing the air. Apparently, however, using all precaution and having the patient carefully watched, Dr. H. Stein (*Wiener Klin. Wochens.*, 1890) has obtained weighable amounts of eliminated quicksilver from the urine four weeks after its inunction. (See also *Viertelj. f. Dermat. u. Syphilis*, 1882; *Annales de Dermat. et Syphil.*, iii., 1882.) Dr. Schuster has found it in the feces three months after the cessation of a mercurial course (*Viertelj. f. Dermat. u. Syphilis*, ix. 307); indeed, he believes that it is thrown off more freely and constantly by the intestines than by the kidneys. He also claims that elimination is completed six months after the cessation of an ordinary mercurial course (*Journ. of Cutan. Med.*, i. No. 12, ii. No. 9). In an elaborate memoir on the elimination of mercury, Balzer and Klumpke (*Revue de Médecine*, vol. viii., 1888) state that extraordinary exacerbations and remissions occur in the elimination during treatment; that Michaelowsky and Souchow have shown that the effect of iodide of potassium is small; but that Stepanow has proved that the hot-air baths increase enormously the elimination. It appears to be established that in these cases of long continuance the mercury escapes not only through the kidneys, but is also excreted by the salivary glands as well as by the intestine, and hence its continuing elimination may be overlooked by the chemist, who simply studies the urine. (See paper by Stein and Kronfeld, *Wiener Med. Wochens.*, 1890.)

† For an article by A. Polotschenow, of St. Petersburg, on the effect of mixing corrosive sublimate albuminate with blood outside of the body, see *Virchow's Archiv*, 1884, Bd. xxi. p. 35. Mercury acts upon the lower mammals as it does upon man, but experimental research has as yet thrown little light upon the method of its action. For the latest research and literature of the subject, see *Arch. f. Exper. Path. u. Pharm.*, xiii. 86.

wasting, the perverted functions of nerves or glandular tissues, the various skin eruptions, all point to a profound influence upon the whole organism. After death from such irritant preparations of mercury as corrosive sublimate, violent diphtheritic colitis is the ordinary lesion, and, as was first shown by Salkowsky, structural alterations abound in the kidneys, accompanied by a peculiar deposit of the phosphate of calcium. That the renal lesions may be produced by the non-irritant preparations of mercury has been shown by Dr. B. Silva (*Central. f. Klin. Med.*, vol. ix., 1888), who has found true desquamative nephritis in dogs to which calomel had been given. For a full discussion of the subject and its literature, see *Virchow's Archiv*, cxviii., 1889, where Dr. Felix Klemperer concludes that the successive changes in the kidneys are: excessive hyperæmia, parenchymatous nephritis, hemorrhagic nephritis, with widespread degeneration of the epithelium, and in about one-half of the cases deposits of chalky material. Virchow states (*Berlin. Klin. Wochens.*, xxv., 1888) that the coexistence of distinct renal chalky deposits, with diphtheritic hemorrhagic colitis, justifies the diagnosis of corrosive-sublimate poisoning, but Klemperer affirms that this condition can be produced by bismuth and some other poisons. This calcification of the kidneys, which is often accompanied by true calcareous deposit in the tubules, and which may be sufficient to cause the kidney structure to cry out under the scalpel, was attributed by Prevost (*Rev. Med. d. l. Suisse Rom.*, 1882-83) to the decalcification of the bones; a theory which seems to have been disapproved by Klemperer, who has been confirmed by Dr. Paul Binet (*Rev. Med. d. l. Suisse Rom.*, 11, 1891) in experiments made in the laboratory of Professor Prevost himself.

That mercury causes no especial waste or destruction of the nitrogenous compounds of the body appears to be shown by the researches of Dr. Hermann von Boeck (*Schmidt's Jahrbücher*, Bd. cxlv. p. 142). This observer analyzed the feces and urine of a man before, during, and after the exhibition of mercury, taking proper precautions to assure uniformity as to diet and exercise. There was a slight but not a notable increase in the amount of nitrogen in the two excretions during the mercurial period.

THERAPEUTICS.—The use of mercury in affections of the liver and of the alimentary canal is fully discussed in another portion of this work; and, although the drug has been used for almost innumerable purposes in times past, it seems here only necessary to speak of its action as an antiphlogistic and as an antisypilitic.

Antiphlogistic action.—The use of mercury in inflammation originated towards the close of the last century with a Dr. Robert Hamilton, and soon became universal in England and America. It is a matter of regret that no sufficient analysis of the blood of pyralized persons has been made to determine exactly what are the changes produced in the vital fluid by mercury. The indications are, however, very strong that chief among them is a lessening of the amount of fibrin.

As is well known, increase of the hæmic fibrin is one of the most characteristic effects of inflammation: consequently, theory, instead of being opposed to the antiphlogistic use of calomel, affords at least some grounds for the belief that there is more or less of antagonism between the processes of mercurialization and of inflammation.

All important evidence as to the antiphlogistic value of mercurials at present available is clinical, and even of this it seems impossible to find much that is very exact and of such nature as to exclude possible fallacies. It is the enormous mass of testimony that overrides the chance of fallacies. It is the general judgment of the profession, founded upon the thousand daily-observed bedside facts, that endorses the use of mercury as an antiphlogistic. In other words, our knowledge of the value of mercurials in inflammation at present is clinical rather than experimental, empirical rather than scientific, but it seems scarcely possible that it is not correct. There is one inflammatory affection, *iritis*, which, from its anatomical relations, is completely visible at all stages; and the effects of the drug upon its processes have been noted from day to day hundreds of times. Oculists are, I believe, agreed that when there is a marked tendency towards the exudation of lymph in this disease, mercury should be exhibited until pyalism is induced.

Of all inflammations, those of the *serous membranes* seem to be most allied to *iritis*; and it is exactly in the condition above spoken of, where there is a tendency to fibrinous exudations in *pleuritis*, *peritonitis*, and *pericarditis*, that mercury is so constantly employed with so good an effect. In parenchymatous inflammations, especially in *pneumonia* and in *hepatitis*, mercury has been used with asserted advantage by many practitioners, but its value is certainly more questionable than in serous inflammations. Calomel is useful in severe *laryngitis*, and especially in the *pseudo-membranous* variety, when the type is *sthenic*; and no time should be lost in bringing the system under its influence. The extent of its power to arrest the course of *endocarditis* is certainly an open question; but, as it is extremely important, if possible, in this disease, to prevent exudation, and as mercury is the most efficient known agent for effecting this, it should be administered freely and at once. If the disease be of rheumatic origin, the alkalies may be administered conjointly with the mercurial.

In whatever disease a mercurial is administered as an antiphlogistic, it should be given during the stage of exudation, and to facilitate the absorption of the newly-organized lymph after it has ceased to be thrown out. In the majority of cases, mercury given for its constitutional effects should be combined with opium, to prevent its acting on the bowels.

Calomel should not be used in *adynamic inflammations*, or where the exudation is serous rather than fibrinous. In *puerperal peritonitis* it has been strongly advocated by some, and as strongly condemned by others,

simply because there are two varieties of the disease, the *sporadic* or *athenic*, and the *epidemic* or *asthenic*; and in the one both bleeding and calomel are strongly indicated, while in the other they are effective only for evil.

Mercury as an Antisyphilitic.—It was formerly believed that syphilis could not be cured without the use of mercury; but latterly there has arisen a school of syphilographers who assert that the drug is not only not necessary, but is at all stages and in all cases of the disease most injurious; that the worst symptoms of the disease are due not to the constitutional affection, but to the remedy given for its relief. The great bulk of the profession occupies a middle ground between these extremes, holding the opinion that while mercury is not absolutely essential for the relief of syphilis, it is yet in many cases of the utmost value when judiciously used. The justice of this position cannot, I think, be rightly questioned; the universal verdict in its favor is too fixed and definite: so that the important point now is to determine at what stages, and under what conditions, the remedy is advisable, and what is the best method of its application.

Syphilis is ordinarily, and with sufficient accuracy for practical purposes, divided into three stages, the primary, the secondary, and the tertiary. According to the teachings of the dualists, there are two varieties, or rather species, of venereal ulcer, the hard and the soft chancre, or the true chancre and the chaneroid, the infecting and the non-infecting sore. When a venereal ulcer offers the characteristic of the latter of these, mercury should never be exhibited. So long as there is a doubt as to the nature of the primary sore, the remedy should be withheld; but when there is distinct induration, and the inguinal glands begin to be involved, it should be given.

It is proper to state that some high authorities deny the expediency of giving the mercurial until the appearance of distinct secondaries. They affirm that mercury is powerless to prevent the occurrence of these phenomena; that the good which it does is found in its hastening their completion, and consequently that it should be reserved until the second stage of the disorder. I myself believe this is incorrect practice, and that minute doses of mercury should be given continuously for many months so soon as undoubted syphilitic symptoms are manifested. The careful experiments of Keyes (*Amer. Journ. Med. Sci.*, Jan 1876) have shown that under these circumstances such small doses act as a tonic, increasing the number of the red blood-disks. Ptyalism is to be avoided unless the symptoms urgently demand it.

In *tertiary* syphilis mercury is to be used cautiously. It is not, however, the mere length of time that has elapsed since the infection, but the condition of the patient, that guides the judicious practitioner. So long as there is no decided cachexia, if the patient has not recently been through a mercurial course, mercury should be freely used when the local lesion threatens life. Thus, a gumma in the heart-wall, in the

upper spinal cord, or in some vital brain-region may imperatively demand active mercurialization. I have twice seen a patient slowly recovering from brain-syphilis under the influence of the iodides die by the accident of an epileptic arrest of respiration. In these cases the more rapid resolution of the gummatous masses by mercury, had that drug been exhibited, would in all probability have prevented the fatal fit. In *hereditary* syphilis a prompt mercurial impression offers the best chance of relief. Even in the *primary* or *secondary* stages of syphilis mercury should be employed with caution and judgment. In his researches (*loc. cit.*) Wilbouchewitch found that the mercurial when first exhibited increased the number of red blood-corpuscles in syphilitic patients, but after a time appeared to produce anæmia. Whatever preparation be employed, it should be so administered as to exhibit only signs of its constitutional action upon the mouth. It is not necessary to ptialize the patient severely, or indeed at all, the proper course consisting in the steady maintenance of the slightest possible distinct soreness of the guma. There are various methods by which this may be done. That most frequently employed, because most convenient, is the administration of small doses of calomel or blue pill by the mouth: from one-fourth to one-half grain of calomel, or twice as much of the blue mass, combined, if necessary, with opium, to prevent its action upon the bowels, may be given three times a day, and increased if required. Instead of the internal use of the mercurial, the system may be brought under its influence by inunctions* with unguentum hydrargyri. When this is done, the skin should be well cleansed and softened by frequent bathing, and then a drachm of the ointment may be rubbed into the inside of the thighs, legs, and the popliteal spaces, in such a way that the application be not made to any spot oftener than every other day.

It is commonly advised in English works to employ the armpits; and, as the skin is there exceedingly thin and the absorbents very numerous, mercury is without doubt more rapidly taken up at that place than at any other part of the body. When, however, mercury is applied to any hairy surface, it very commonly in a short time induces a troublesome eruption, due to inflammation about the hair-follicles. The eruption appears anywhere on the skin if the mercurial ointment be applied too freely; and, in order to avoid this inconvenience, in Germany the following plan is adopted (Dr. H. Zeissl, *Lehrbuch der Syphilis*, Theil ii. p. 349): the patient, having been prepared by thorough warm bathing, and having received about half a drachm of the ointment, is directed to place it in the hollow of the hand and to rub

* Quinquad claims that an effective and, in some cases, advantageous method of mercurializing the system is to thoroughly wash the skin over the splenic region and apply thereto plaster according to the following formula. He states that mercury appears in the urine four days after the application, and that he has found it six weeks after the removal of the plaster. R. Diachylon plaster, ℥i; Calomel, ℥xx; Castor oil, ℥vj. M. and make into a plaster, 4 by 4 inches, or spread on cloth and divide into squares of the above size.

the two hands together until the ointment is equally diffused, then to apply it forcibly and slowly to the part directed until almost all of the salve has disappeared, having been rubbed into the skin. In most cases the mercurial is applied daily, but in very susceptible persons only every third day. A regular order is maintained in the application, as follows: *first day*, inner side of both upper arms; *second day*, inner side of both thighs; *third day*, inner side of both forearms; *fourth day*, inner side of both legs; *fifth day*, upon both groins; *sixth day*, upon the back; *seventh day*, recommence the series.

The advantage claimed for inunction is that the digestion is less apt to be disturbed than when the drug is exhibited by the mouth;* the disadvantages are the greater or less publicity which it entails, the trouble which it involves, and its apparent dirtiness. In private practice it is rarely used except in the case of infants, when the mercurial ointment is rubbed into the abdomen and armpits, or often simply smeared upon the flannel roller or binder which usually envelops the body. The mercurialization of the nurse, with the object of affecting the child, is unjustifiable, unless the nurse and the nursing are alike diseased: indeed, to allow a syphilitic child to feed at the breast of a healthy woman is a crime.

In syphilis, mercury has been used by many practitioners hypodermically, with the result of enormously stimulating the chemists to the invention of new preparations and the clinicians to the production of an overwhelming literature. The number of preparations suggested and of pages covered with type is in itself sufficient to show that the method either has insuperable objections to it or else has not been sufficiently developed to warrant its general use. If there were any one preparation of mercury or any one method of hypodermic medication that really answered, the consensus of opinion could be expressed in a few lines.

My own judgment in the matter has perhaps been biased by the fact of calomel injections given by myself some years ago in the most careful manner, and by the method at the time most approved by the Viennese syphilographers, having resulted in local sloughing, which had much to do with the bringing about of a fatal result. It is not possible in the scope of this volume to really discuss the literature of the subject, and I content myself with referring the reader to a very thorough and elaborate article from the pen of Professor J. William

* The action of inunctions is usually very mild and tractable, but Von Sackar (*Berl. Klin. Wochenschr.*, xxix., 1892) has reported a case of death in six days, preceded by symptoms of violent irritation of the stomach, the intestines, and the kidneys, with furious gangrenous pyelitis, apparently produced by a single inunction with mercurial ointment. Professor Ludwig, of Vienna, in an examination to determine the distribution of mercury given by inunction, found that it was most abundant in the kidneys, liver, and spleen; then in the alimentary canal (least in the stomach and most in the large intestine). In the muscles the amounts were variable, in the cerebrum never sufficient to be weighed (*Internat. Klinisch. Rundschau*, vi., 1892).

White, which may be found in the second volume of "The System of Genito-Urinary Diseases" (Appleton & Co., 1893).

In obstinate cases of syphilis in which it is found impossible to mercurialize the patient by the ordinary methods, the hypodermics may be used. My personal preference is for the simple solution in distilled water of corrosive sublimate, one-sixth to one-twelfth of a grain of the mercurial being given at a dose, and the injection repeated daily or every other day, *pro re nata*. A great deal of pain is produced at the time, but I think the danger of severe local accidents is less than with more insoluble though less irritating mercurial preparations. Dr. Carl Ullmann (*Wien. Klin. Wochen.*, 1892) highly commends as an excipient in these cases a mixture of liquid paraffin and lanolin. Two of his formulas are appended.

R Hydrarg. salicyl., 6 parts;

Petrolati liquidi, 4 parts;

Lanolini anhydr., 2 parts.

1 C.c. = 0.37 Hg. Injection temperature, 23° C.

R Hydrarg. chl. mit.,

Petrolati liquidi, aa 4.5 parts;

Lanolini anhydr., 4 parts.

1 C.c. = 0.371 Hg. Injection temperature, 24° C.

Mercury is sometimes administered in secondary syphilis in the form of fumigations. The patient is placed upon a chair, and surrounded by a large blanket, or, better, india-rubber cloth, so arranged as to fit tightly around his neck above, and below to encompass the chair. The mercurial preparation is placed upon a metal plate, heated by a spirit-lamp, beneath the chair, and the fumes are allowed to fill the space around the patient inside of the blanket. The heat produced generally causes the patient to sweat profusely, and in from fifteen minutes to half an hour the lamp should be withdrawn, and the patient allowed to cool off, and after a time be put to bed and wrapped up in blankets, with the deposit of mercury still adhering to the skin. The fumigation may be practised every other night, or at longer intervals, and is believed by some to be especially useful in cases of secondary skin-eruptions. Calomel, black oxide, and cinnabar are the preparations generally used. When the last is employed, care must be exercised that the patient do not breathe the fumes.

In advanced secondary and tertiary syphilis, the iodides of mercury, given by the mouth, are often very useful, but the combination of the corrosive sublimate and the iodide is in many cases still more efficient. Usually not more than one-twelfth of a grain of the bichloride should be given, three times a day.

ADMINISTRATION.—The following preparations contain metallic mercury:

Unguentum Hydrargyri, U.S.—*Blue*, or *Mercurial*, Ointment is made by triturating mercury with suet and lard until the metal is exten-

guished.—i.e., until a portion of the mass rubbed upon a piece of paper exhibits no globules under a magnifying power of ten diameters. Mercurial ointment is soft, of a bluish color, becoming darker by age, and contains half its weight of mercury. When frequently rubbed upon the same part, it not rarely produces a disagreeable eruption. It is used to make a constitutional impression, and also locally as a resolvent, in cases of enlarged indurated glands. The oleate of mercury (*Oleatum Hydrargyri*—20 per cent., U.S.) is considered by some practitioners to be a more elegant preparation than blue ointment, and equally efficient.

Emplastrum Hydrargyri, U.S.—Mercurial Plaster contains mercury, oleate of mercury, and lead plaster, and is used as a resolvent in indurated glands, enlarged chronically inflamed joints, etc.

Massa Hydrargyri, U.S.—Mass of Mercury—Blue Mass is made by extinguishing mercury with honey and other inert substances. It contains one-third its weight of the metal, and is used for the same purpose as calomel, but is milder. Dose: purgative, grains 5 to 10; alterative, grains 1 to 3. "Blue Pills" usually contain each three or five grains of the mass.

Hydrargyrum cum Creta, U.S.—Mercury with Chalk—Gray Powder is made with chalk. It is a smooth, grayish powder, and is similar in its medical properties and strength to blue mass.

HYDRARGYRI CHLORIDUM MITE—MILD MERCUROUS CHLORIDE. U.S.

Calomel is made by boiling mercury and sulphuric acid together in such proportions as to form a bisulphate of the deutoxide of mercury, reducing this to the simple sulphate of the protoxide of mercury by triturating it with more of the metal and subliming with the chloride of sodium. The sublimate is to be well washed with water, to remove any of the bichloride that shall have been formed owing to the imperfect reduction of the bisulphate to the sulphate. When the washings are no longer affected by the addition of ammonia, it may be known that the drug is free from the soluble corrosive sublimate. Calomel is sometimes manufactured by precipitating corrosive sublimate by sulphurous acid; but this method is not officinal, and is subject to serious disadvantages.

PHYSIOLOGICAL ACTION.—Owing to the great insolubility of calomel, a good deal of discussion has occurred as to the way by which it finds entrance into the system. The theory of Mialhe (*Chimie appliquée*), a modification of one originally advanced by Snow (*Lancet*, 1840), has been pretty widely accepted, though with some hesitation, but is, I think, untrue. According to the chemist named, the calomel is converted by the chlorides of the stomach into corrosive sublimate, and as such is absorbed. The action of calomel upon man is so different from that of corrosive sublimate as to render this theory exceedingly improbable, and, at temperatures even higher than that of the stomach,

Mialhe was never able to obtain the formation of more than a sixteenth of a grain of the sublimate by the gastric juices. Further, Buchheim, Oettingen, and Winkler (quoted by Professor Stillé, *Therapeutics*, 2d ed., p. 655) affirm that this conversion does not occur at all at the temperature of the body. Jeannel (*Schmidt's Jahrbücher*, Bd. cxliii. p. 9; from *Journ. de Bordeaux*, 4e sér., t. ii. p. 67, 1869) has confirmed this, and has suggested what seems to be the way in which calomel is absorbed. He finds that when the protochloride of mercury is placed in a solution of an alkaline carbonate it is decomposed and the gray oxide precipitated. A small portion, however, of the latter is held in solution, as much as 0.02 part in 50 parts of water (by weight); and if a fatty oil be mixed with the alkaline solution a very large part of the mercury is dissolved. From these facts it would seem to follow that the calomel entering the stomach escapes unchanged into the alimentary canal, and is there decomposed by the alkaline juices and dissolved by the fatty matters usually present. The physiological evidence appears to confirm this, for calomel, being absorbed in this way, ought to resemble blue mass rather than corrosive sublimate in its action,—which it does.

The varying constitution of the alimentary juices and the complex chemical relations of calomel would indicate that its solution in the alimentary canal is accomplished in more ways than one,—an indication which is confirmed by the varying results following the ingestion of the drug. It is possible that at times, when the stomach contains more than usual of chlorides and of hydrochloric acid, a very slight portion of the calomel is converted into corrosive sublimate, and that when there is an excess of sulphuretted hydrogen in the alimentary canal a soluble sulphide may be formed.

Since the labors of Hunter and Hebra, syphilographers have been experimenting with the hypodermic use of mercury. That it is possible to produce the mercurial impression very rapidly and very successfully in syphilis by such method is proved beyond cavil. The practical difficulty has been the production of local abscesses. It is said that by Smirnov's modification of the plan of Scaresio this obstacle has been largely overcome. The preparation used is calomel mixed with water and chloride of sodium in such manner that the mixture contains ten per cent. of each ingredient. It is essential that the hypodermic injection be made in the buttocks, in the neighborhood of the vertical fold or depression which occurs in most lean persons about one inch and a half behind the great trochanter. According to Smirnov, the advantages of this treatment are its simplicity and ease, its efficiency, and the little liability to produce serious mercurialization. One and a half grains of calomel may be used in each injection the two injections being administered at once on opposite sides of the body. The injection should not be repeated in less than four days, and may be employed only once a week. I tried the plan in one case, with the result of a sloughing ulcer two inches deep. Various other preparations of mercury have

been used instead of calomel; especially is the yellow oxide suspended in liquid vaseline commended by Balzer and other French physicians. It appears, however, to produce more irritation than does calomel.* Bellini states that severe constitutional symptoms are liable to be produced in persons who are taking alkaline iodides or bromides.

The influence of calomel upon the system has been sufficiently discussed. It remains only to state that its freedom from all irritant properties is shown when taken internally or when used externally. Probably no single dose of it is capable, in the average man, of acting as a violent poison, since it is stated that in the Western United States it is very frequently taken in teaspoonful doses, that sixteen grains of it will act as vigorously as an ounce, and that a pound of it has been given in a case of cholera without visible effect.† It seems to me most probable that the absence of serious results from these heroic amounts is due to the alimentary canal being unable to dissolve—i.e., to absorb—the calomel. F. D. Lente has claimed that given in this way the drug acts as a sedative and does not produce mercurialization, and Mrs. Putnam-Jacobi believes such doses to be valuable in diseases where there is "sudden over-distention and paralytic congestion of extensive regions of small blood-vessels." (See *New York Med. Journ.*, xi., 1870; xxix., xxx., 1879.) For use of calomel as a diuretic and in dropy, see **DIURETICS**.

ADMINISTRATION.—When it is desired to produce constitutional mercurialization, the dose of calomel is a half to one grain; as a purgative, from six to ten grains are administered, and followed in six hours by Seidlitz powder, or other saline, if required; or, as is preferred by some practitioners, a quarter of a grain is given every hour until three grains are taken or purgation is induced. Minute doses (one-sixth of a grain) of calomel given every hour afford a very good method of impressing the system rapidly. When it is desired to get its constitutional influence, it is generally necessary to conjoin opium with it, to prevent purging.

HYDRARGYRI CHLORIDUM CORROSIVUM—CORROSIVE MERCURIO CHLORIDE. U.S.

Bichloride of Mercury, or *Corrosive Sublimate*, is made by subliming the bisulphate of mercury with common salt. It occurs in the form of colorless crystals, or of white, semi-transparent, crystalline masses, of an acrid, metallic, styptic, and very persistent taste, soluble in sixteen parts of cold and in two of boiling water. It is at once distinguished from the other mercurial preparations by its color, taste, and solubility, and by its forming a yellow precipitate with lime-water.

* Consult *Lo Sperimentale*, June, 1873; *London Medical Record*, 1873; *Klinikor, Centralbl. für Chir.*, 1877, 97; *Bull. Gén. de Thérap.*, cxii. 302; *Med. Wochenschr.*, No. 6, 1887; *N. Y. Medical Record*, July, 1887.

† Professor George B. Wood's *Therapeutics*, vol. ii. p. 565.

PHYSIOLOGICAL ACTION.—Corrosive sublimate is a violent irritant, and in concentrated form caustic. When given in small repeated doses, although capable of inducing salivation, it is less apt to do so than is calomel or blue pill. In overdoses it produces symptoms of irritant poisoning of a severity proportionate to the dose. If the latter be small, the manifestations may be only some nausea, slight burning in the stomach, colicky pains in the abdomen, and diarrhoea. After large doses these symptoms are intensified. The subject first experiences a peculiar metallic, coppery taste at or shortly after swallowing the poison. If the solution be concentrated, deglutition is interfered with by a spasm of the muscles of the throat and larynx, causing a feeling of suffocation, and sometimes even the rejection of the draught. Then burning pains are experienced in the oesophagus and stomach, followed by violent vomiting, at first mucous, then bilious, and finally bloody, and by severe abdominal pain and tenderness, with profuse purging, at first serous in character, but afterwards affording only small, mucous, bloody stools, which are often voided with much straining. The breath generally becomes fetid and offensive in a very short time. In the course of two or three hours, very rarely in less than an hour, collapse occurs, with small, frequent, irregular pulse, pinched, anxious face, cold extremities, and finally death, preceded, it may be, by fainting, convulsions, and coma. The urine is very much lessened in quantity, is sometimes albuminous, or even bloody, and not rarely is suppressed. If the patient survives several days, a petechial eruption may appear, and salivation sometimes, but not always, occurs. In some cases, after the collapse there is an attempt at a febrile reaction, which soon, however, gives place to a second and fatal prostration. When recovery occurs after severe poisoning, the convalescence is slow and protracted.

In regard to chronic poisoning with corrosive sublimate, sufficient has been said under the general heading, except that colicky pains and abdominal disturbance are more apt to occur with it than with the less irritating preparations. MM. Arnozan claim that chronic catarrh of the excretory ducts of the pancreas is a pronounced lesion in chronic poisoning of animals (*Journal de Bordeaux*, Dec. 1883). It should be looked for in man, and its presence might be of medico-legal value.

Severe purging, and even fatal poisoning, may result from a single external application of this preparation of mercury;* and in animals killed by hypodermic injections of it (see experiments of Dr. J. Rosenbach, *Schmidt's Jahrbücher*, Bd. cxliii. p. 9) diarrhoea and other indications of gastro-intestinal irritation are prominent symptoms,—facts

* See case reported by Dr. Meeres, *Lancet*, Sept. 16, 1871, in which a solution (gr. ii to ℥i) was applied with a camel's-hair brush to the head of a child nine years old, for the cure of tinea tonsurans. The symptoms were diarrhoea, profuse salivation, and great prostration, ending in death. Washing out the vagina with a solution of corrosive sublimate, one part in twenty thousand, has caused severe and even fatal poisoning. See *Zentralbl. für Gynäkol.*, 1884, No. 13, No. 17; also 1887, No. 47.

which indicate that the bichloride is eliminated unchanged from the alimentary canal. Dose, one-eighth to one-one-hundredth of a grain.

HYDRARGYRI IODIDUM FLAVUM.—*Yellow Mercurous Iodide*, U.S., is a greenish-yellow, odorless, and tasteless powder, insoluble in water, ether, and alcohol. Compared with the biniodide or the bichloride, it is a mild preparation, and has been used to produce constitutional impression in *syphilis*, especially when of long standing. The iodide of potassium converts it into the biniodide and metallic mercury (U.S. Dispensatory), and should, therefore, never be given in combination with it. The alterative dose is one-fourth of a grain three times a day, increased to a grain if necessary.

HYDRARGYRI IODIDUM RUBRUM.—*Red Mercuric Iodide* is a scarlet-red powder, almost insoluble in water, but sparingly soluble in alcohol. It is a powerful local irritant, producing, when taken in overdoses, symptoms and results very similar to those caused by corrosive sublimate. It is much used in *tertiary syphilis* and in *syphilitic rheumatism*; also to some extent as a local application in *lupus*. It is much more active than the protiodide, and should be administered as cautiously and in the same doses as corrosive sublimate.

The U.S. Pharmacopœia also recognizes the following preparations of mercury:

The mercuric oxide occurs in two forms, the *Yellow* and the *Red Oxide* (**HYDRARGYRI OXIDUM FLAVUM**, **HYDRARGYRI OXIDUM RUBRUM**). Both are used upon *ulcers*, *chancres*, etc., solely for their local effects, and are stimulant and alterative when diluted, mildly escharotic when in powder.* From *Hydrargyri Oxidum Flavum* is made the *oleate* (*Oleatum Hydrargyri*—20 per cent., U.S.). The *Red Precipitate Ointment* (*Unguentum Hydrargyri Oxidi Rubri*—10 per cent., U.S.), the *Ointment of the Yellow Oxide* (*Unguentum Hydrargyri Oxidi Flavi*—10 per cent., U.S.), and the *Citrine Ointment* (*Unguentum Hydrargyri Nitratis*—7 per cent., U.S.) very generally require dilution with lard, and are much used in chronic skin-affections, in obstinate conjunctivitis, in *psorophthalmia*, etc.

Turpeth Mineral, or *Yellow Mercuric Subsulphate* (**HYDRARGYRI SUBSULPHAS FLAVUS**, U.S.), a lemon-yellow powder, sparingly soluble in water, is a basic sesquisulphate of the deutoxide of mercury, prepared by throwing the bisulphate into water, which causes it to break up into a supersulphate, which remains in solution, and the salt in question, which precipitates. Turpeth mineral has been used as a harsh emetic, and also as an alterative, but is now rarely employed. In *croup*, in emetic doses it is still very highly esteemed by some practitioners, and has been inordinately praised by Dr. Fordyce Barker. It is, however,

* For severe poisoning by yellow oxide, see *Brit. Med. Journ.*, Sept. 1889.

a very dangerous remedy, since, if it fail to vomit, it may cause a fatal gastro-enteritis, especially in the young child. Two cases of such character are recorded by Dr. A. McPhodran (*Med. News*, xliii. 682). The dose as an alterative is from a quarter to half a grain; as an emetic, for a child two years old, two grains repeated in fifteen minutes, if it has not operated. Forty grains of it (*Guy's Hospital Reports*, vol. x., 3d series) have caused death in the adult; profuse salivation came on in six hours.

White Precipitate, or *Ammoniated Mercury* (*HYDRARGYRUM AMMONIATUM*, U.S.), is a white complex powder, made by precipitating the bichloride with water of ammonia. It is used in the form of ointment (*Unguentum Hydrargyri Ammoniaci*—10 per cent., U.S.) as a local application in various skin-affections.

Black Wash and *Yellow Wash*, two non-official but favorite preparations, are respectively made by the addition of a drachm of calomel to a pint of lime-water, and of half a drachm of corrosive sublimate to a pint of lime-water. They depend for their virtues upon the black and yellow oxides of mercury, and are used exclusively as local applications to *chancres* and other *syphilitic ulcers*. The yellow wash is much the more stimulating of the two.

AURI ET SODII CHLORIDUM. U.S.—GOLD AND SODIUM CHLORIDE.

This salt of gold, which may be obtained in large, golden-yellow, prismatic crystals, is, according to the requirements of the U.S. Pharmacopœia, a slightly deliquescent powder, having an odorless but a saline and metallic taste. It is freely soluble in water.

PHYSIOLOGICAL ACTION.—The precise action of the preparations of gold upon the animal organism is not at all understood, but it is probable that the soluble preparations are mostly irritant poisons, whilst the insoluble preparations are either not poisonous or else act slowly upon the general system. It is stated that gold and sodium chloride, in overdose, produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effect of gold preparations, in moderate doses, is to produce increased fulness and frequency of the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

THERAPEUTICS.—Although gold and sodium chloride has been largely used by clinicians, its exact action, and indeed its real value, is still a matter of doubt. It is believed, however, by many to have a distinct influence upon the general nutrition, and especially upon the nutrition

of the nervous system. The various uses of it may be discussed under distinct headings.

First, as a nerve tonic.—It has been used quite largely, especially by gynecologists, many of whom believe that it has a specific direction to the genital organs, in *neurasthenia*, in *hysteria*, in *neuralgia*,—especially in *ovarian neuralgia* and in *ovarian irritation*,—and in other conditions of depressed nerve power. It has also been much used as an alterative tonic in the treatment of the *alcohol habit*. It is true (see "Alcoholism and its Treatment," J. E. Usher, 1892) that analysis has shown that most, if not all, of the advertised gold nostrums for the cure of alcoholism contain no gold in any form; but the most reliable obtainable information indicates that at the Keeley Institutes, so called, the treatment consists chiefly of the administration of varying doses of the gold and sodium chloride, with hypodermic injections in the interim (every three hours) of very minute doses of atropine and strychnine. It is incredible that any medication can work moral reformation; and the extraordinary results which have been sometimes achieved in the Keeley Institutes are balanced by numerous failures, and have probably been only in small part, if at all, directly due to the medical treatment. Nevertheless, in some trials which I have myself made, it did appear that the treatment just spoken of, by pushing up the nervous system and bringing about a general increase of nutritive tone, aided persons who were determined upon reform. It has seemed to me that the gold salt has some influence in overcoming the physical conditions of chronic alcoholism.

Secondly, as an alterative.—The gold and sodium chloride has been commended by various practitioners in *scrofula*, advanced *syphilis*, *chronic rheumatism*, and in *chronic diseases of the joints*. Professor Charles G. Stockton (*International Clinics*) claims that it has a special influence upon the lithæmic and fatty degenerations which are prone to occur in advanced middle life. The salt is also employed with alleged excellent results in the various *spinal* and *cerebral sclerosis*. In my own somewhat limited experience with it I have thought it in some of these cases to be of service.

ADMINISTRATION.—The gold and sodium chloride may be given in solution or in pill, in doses of one-twelfth of a grain, increased to one-sixth or even one-fourth, three times a day. It may also be administered hypodermically, producing some pain, but usually no serious or permanent local irritation. In many cases in which it has been used the moral effect of the hypodermic injection is perhaps greater than the direct influence of the remedy.

INSOLUBLE GOLD PREPARATIONS.—The *oxide*, *iodide*, and other insoluble preparations of gold have been recommended as alteratives in *scrofula*, *skin-diseases*, and *secondary syphilis* of various forms, in doses of from one-fifteenth to one-tenth of a grain, three times a day.

IODUM—IODINE. U.S.

Iodine is a soft, friable, opaque substance, occurring in crystalline scales with a semi-metallic lustre and of a bluish-black color. Its odor resembles that of chlorine; its taste is hot and acrid. It is somewhat volatile at ordinary temperatures, but when heated to 237.2° F. melts and emits the beautiful purple or violet vapor to which it owes its name. It is freely soluble in glycerin, alcohol, and ether, but requires five thousand times its weight of water to dissolve it. With starch it strikes a deep-blue color, and this test is so delicate that it will indicate the presence of iodine in four hundred and fifty thousand times its weight of water. In testing animal liquids, such as urine, for iodine, a small quantity of nitric acid should be added to insure its being free in the liquid.

PHYSIOLOGICAL ACTION.—Iodine, when applied to any part of the body, acts as a very powerful irritant, or, if in highly concentrated form, as a mild caustic. The tincture stains the skin yellow, and causes, if applied with sufficient freedom, smarting, some erythematous inflammation, and finally desquamation. Its repeated application blisters and destroys the cuticle. Upon mucous membranes its action is more intense than upon the skin.

When taken internally, a single moderate dose of iodine causes merely some gastric uneasiness and a disagreeable metallic taste in the mouth; when larger amounts are ingested, the gastric uneasiness may be intensified into violent vomiting, with increased salivary flow, abdominal pains, and even purging. In sufficient quantity it is a poison; although very few deaths have been recorded as caused by it. The symptoms produced by toxic doses taken into the stomach are burning pain in the œsophagus and stomach, vomiting, purging, smallness of the pulse, general deadly pallor, lessening or arrest of the urinary secretion, sometimes violent excitement with convulsions, and collapse. Twenty grains of iodine are said to have caused death, and two drachms and a half have been recovered from. (For cases, see Woodman and Tidy, also *Munchener Med. Wochenschr.*, Feb. 1887.) The vomit is yellowish brown or, if starchy matters have been present in the stomach, bluish. The injection of iodine into the cavities of the body for therapeutic use has several times been followed by cyanosis, thready pulse, repeated vomiting of matters containing iodine, excessive thirst, salivation, difficult urination, swelling of the eyelids, laryngeal pain, various eruptions upon the skin, high fever, and albuminuria. Sudden death may take place after some days from heart-failure. A characteristic case is that reported by Dr. E. Rose (*Nothnagel's Arzneimittellehre*, Berlin, 1870, 252), in which death resulted from a large injection into an ovarian cyst. Very soon after it was given, there ensued severe thirst, with great dryness of the throat and mouth, and then painless vomiting of watery matters containing iodine. The whole surface became

very pale, the extremities cyanosed, the radial pulse very frequent, but so small that it could not be counted, the urine very scanty, dark brown, and rich in iodine. After a time, reaction occurred. For three days the vomiting persisted, the pulse was very frequent, full and hard, and the cheek put on the glow of high fever, but the temperature did not rise above 37.18° C. On the fourth day, exanthematous blotches, not disappearing on pressure, appeared on the skin and in the mouth; the sputa became bloody; and menstruation occurred, two and a half weeks too soon. The urine remained scanty, and on the eighth day, when all other symptoms save swelling of the parotids had disappeared, still contained iodine, and was albuminous. On the tenth day, in the midst of apparent convalescence, the patient died suddenly. In a case reported by Dr. W. O. Culpeper (*Therap. Gaz.*, vol. iv., 1888) two drachms of a tincture used externally on a child of eleven years destroyed all the skin from above the knees to below the ankles. After twenty-four hours there developed headache, backache, some diarrhoea, vomiting, great thirst, constant desire to urinate, suppression of urine, priapism, giddiness; finally dysentery without rise of temperature, hiccup, hemorrhage from bowels, great giddiness, and death on the sixth day.

In the experiments of Jörg and his pupils, doses of iodine of a grain to a grain and a half gave rise to colicky pains, increased appetite, watery stools, an increased secretion of urine, malaise, and some headache. When the dose was augmented to two grains, a diffused sense of heat and sexual excitement were superadded. Other observers have noted this abnormal sexual excitement, and some have stated that at times it precedes atrophy of the mammae or of the testicles. Professor Stillé affirms that the menstrual flow may become excessive, or that during pregnancy abortion may be caused. Very large quantities of iodine are asserted to have been taken without serious results. Julia de Fontenello (quoted by Stillé, *Therapeutics*, ii. 731) tells of a man who took two and a half drachms of iodine without experiencing any remarkable effects; and Magendie relates the case of a child four years old who swallowed ten grains without serious consequences.*

In the experiments of A. Høyges and Professor Binz (*Arch. f. Exper. Path. u. Pharm.*, x. 229, xiii. 114), preparations of iodine, iodide of potassium, and iodoform in fatal doses produced in the lower animals wide-spread fatty degenerations.

If full doses of iodine be exhibited continuously for a length of time, a train of phenomena result, known as *Iodism*. In regard to these there has been a good deal of difference of opinion and statement, a difference which seems explainable only upon the supposition that different individuals are differently affected by the drug. Rilliet (Trousseau's report on his memoir, *Bull. de l'Acad. Roy.*, xxv.), who has

* For an elaborate, careful study of the action of large toxic doses of iodine upon the lower animals, see Hoffmann and Schwalbe's *Jahresbericht*, 1879, 189.

had wide opportunities and has apparently studied the subject very closely, makes three forms of Iodic intoxication: first, that in which the symptoms are those of gastric irritation; second, that characterized by nervous troubles, neuralgia, ringing in the ears, convulsive movements, disturbed intellection, with coryza, ophthalmia, salivation, vomiting, diarrhoea, polyuria, and cutaneous eruptions, and in some cases atrophy of the mammae in the female and of the testicles in the male;* third, Iodic cachexia, caused either by iodine or iodide of potassium continuously used for many months. It is said to be most easily induced in goitrous persons, and is characterized by rapid emaciation, commencing mostly in the face, and severe nervous palpitations of the heart, with excessive appetite, which sometimes precedes and sometimes follows the loss of flesh. So long as the drug continues to be taken, these symptoms continue to progress, and after a time hysteria or hypochondriasis, with insomnia, manifests itself. The goitre, the mammae, and the testicles waste away together; but if the medicine be suspended and health gradually returns, while the abnormal growth reappears, the sexual glands remain wasted. The second form of iodism of Rilliet, in which the nervous symptoms are prominent, has been spoken of by other authorities; and Brodie has especially noted disturbances of vision, and paralysis. In some rare cases neuralgic pains and other disturbances of nerve-functions have occurred, indicating that iodine is capable of causing a peripheral neuritis. •(See *Therapeut. Monatshefte*, Bd. iii., 1888.)

Iodism as I have seen it after the therapeutic use of the drug has chiefly consisted of affections of the skin or of the mucous membranes of the nose and mouth. The symptoms are heavy pain over the region of the frontal sinus, coryza, sore throat, ptyalism, and an eruption upon the skin, which is usually an acne, but may take almost any shape. In its serious forms it becomes pustular or bulla-like, and may be accompanied with much dermatitis, ulceration, and even very violent constitutional disturbances. A remarkable Iodic dermatitis tuberosa has been noted by Besnier, Duhring, and R. W. Taylor (see *New York Med. Journ.*, November, 1888). Iodic accidents are especially apt to be severe when there is kidney-disease, as in a case reported by Dr. F. Wolf (*Berlin. Klin. Wochenschr.*, 1886, p. 580), in which forty grains of iodide of potassium given in two days appear to have produced death. (See also *Journ. Cutan. and Vener. Dis.*, iv.; *Munchener Med. Wochenschr.*, vols. xxxiii. and xxxiv.)

Most authorities affirm that iodine and iodide of potassium produce similar symptoms. Professor Sée (*London Med. Record*, i. 777) indeed asserts that iodine exists in the blood only in the form of an alkaline iodide, while Dr. H. Kämmerer (*Virchow's Archiv*, lix. 467; lx. 527) and Professor Binz believe that the iodides are decomposed in the

* For a case of wasting of the testicles, see *Phil. Med. Times*, vol. iv. p. 681.

tissues and act by the liberation of the iodine.* I do not think, however, that these views can be accepted as completely established, and the general professional belief is that the therapeutic value, and consequently the physiological action, of iodine and iodide of potassium are different. Iodine is universally preferred in scrofulosis, the iodide in rheumatism. I have given the salt in enormous doses, and have seen nervous symptoms in only a single case,—a man who received for a long time two hundred and seventy grains a day, and who was intensely sleepy and stupid, presenting symptoms exactly similar to those of bromism, including an eruption of acne. Potassium iodide is said to sometimes produce sudden œdema of the glottis, accompanied by excessive dyspnoea, and ending, unless tracheotomy be performed, in death (nine cases, Dr. A. Groenouw, *Therap. Monatshefte*, 1890).

Iodine and its salts are certainly absorbed, entering into all the tissues and fluids of the body, and, contrary to the old assertions, even into serous and other exudates (see Dr. G. Leuch, *Centralb. Klin. Med.*, 1890). The iodine is eliminated partly as an alkaline iodide and partly in organic combination (E. Harnack, *Berlin. Klin. Wochensh.*, 1882). It has been found in the secretions of the skin (Dr. R. W. Taylor, *Amer. Journ. of Syphilog. and Dermat.*, 1873), and, according to Sée (*London Med. Record*, i.), may exist in the saliva after it has disappeared from the urine. It probably escapes also to some extent from the intestines, but its chief channel is through the kidneys. In a patient under my care, taking daily three hundred and sixty grains of the iodide of potassium, Dr. John Marshall recovered daily two hundred and sixty-five grains from the urine (see also Ehlers, *Ann. de Dermat. et Syph.*, 1890). Professor Sée states that its elimination is apt to be irregular, so that the drug may accumulate in the system. The action of the iodides upon the circulation has been studied by various experimenters with somewhat contradictory results. Rose (*Virchow's Arch.*, Bd. xxxv.) believed that the iodide produced a vascular spasm, but most subsequent observers have claimed dilatation of the small vessels, and Sée and Lapique (*Bull. Acad. d. Méd.*, xxii., 1889) believe that the iodide of potassium acts like digitalis upon the heart, but that it also dilates the vessels, and in this way relieves aneurism, asthma, etc. (see also Pierrot, *Nancy Thesis*, 310, 1890). On the other hand, Prevost and Binet (*Revue Méd. Suisse Rom.*, 1890), have come to the conclusion, with apparent correctness, that watery iodic solutions slowly injected into the veins

* Consult also Professor Buchheim (*Arch. f. Exper. Path. u. Pharm.*, Bd. iii.). Dr. Dubajadoux (*Gas. Hebdom.*, 1883, xx. 24) found that iodine injected into guinea-pigs suffering from malignant pustule has no influence upon the disease, even if the injections be repeated until they kill the animal, and that the blood also is as poisonous as ever to other guinea-pigs. This led him to believe that the iodine exists in the blood in a new compound which is not antiseptic. He believes this compound to be albuminous, because he has found that iodine mixed with milk or albuminous solutions soon disappears, so that it cannot be recognised by the starch test, and that shortly after this disappearance putrefaction sets in.

have no effect upon the circulation unless in overwhelming amount; nevertheless the iodide of potassium injected into the veins when in very feeble dose causes temporary rise, but when in large dose marked depression of the arterial pressure. It seems to me very apparent that the action of iodine and the iodides upon the circulation is very feeble, and from a therapeutic point of view has no value.

Iodine is certainly absorbed and is eliminated chiefly by the kidneys, but probably to a greater or less extent by all the mucous membranes; and Dr. R. W. Taylor (*American Journal of Syphilography and Dermatology*, April, 1873) believes that he obtained in a case evidences of the free escape of the iodine through the skin. Professor Sée asserts (*London Med. Record*, i. 757) that the elimination takes place slowly and intermittently, so that the drug when given continuously accumulates in the system. He further states that it can be found in the saliva after it has disappeared from the urine. The iodine seems to be eliminated partly as an alkaline iodide and partly in organic combination (E. Harnack, *Berlin. Klin. Wochenschr.*, 1882, No. 20).

During its passage through the kidneys iodine undoubtedly exerts an influence upon those organs, as is shown by its producing albuminuria at times. It is indeed asserted that it occasionally causes a true tubular nephritis. The evidence as to its effect upon the solids of the urine is both contradictory and insufficient. M. Rabuteau* dieted himself for five days, measured the quantity of urea daily eliminated, took iodine on the fifth day, and found a decided decrease in the excretion of urea. It is plain that this experimentation was too slight to be of much value, and Dr. Hermann von Boeck (*Zeitschrift für Biologie*, iii. 393, 1869; *Schmidt's Jahrbücher*, Bd. cxlv. p. 142) found that the ingestion of iodine does not increase notably the elimination by the kidneys or bowels. On the other hand, M. Bouchard (quoted by Sée) declares on his personal experience that iodine does increase the daily elimination of urea, especially in diabetic patients. Dr. C. Handfield Jones (*Beale's Archives*, i.) analyzed the urine of six patients taking large doses of iodide of potassium, with the following results: first, water increased in three cases very much, in one slightly so, in two diminished; second, acidity increased in three and diminished in two; third, urea increased in three and diminished in three; fourth, phosphoric acid and sulphuric acid increased in four and diminished in two; fifth, chlorine increased very greatly in two cases, moderately in one, and decreased in two; sixth, uric acid increased very greatly in two cases and diminished in four. Dr. Eugene I. Duchesne (*Inaug. Diss.*, Paris, 1885) found that the iodide of potassium and the tincture of iodine notably increased the elimination of urea, while iodide of sodium was followed by a distinct decrease of this excretion. All the preparations of iodine used increased the elimination of uric acid. On the other

* Quoted by Sée.

hand, Dr. A. Haig affirms that the iodides have a marked effect in lessening the elimination of uric acid and the urates, and as a result of this diminish the arterial tension (*London Lancet*, i., 1893).

THERAPEUTICS.—As an alterative, iodine is of especial value in *chronic scrofula*. In those cases in which there is indolent enlargement of the lymphatics, which exhibit no tendency, or but little tendency, to suppurate, it is of especial value. Except in very acute cases, however, it should always be tried, even when the glands do tend towards suppuration, especially as it exerts a very beneficial influence upon the ulcers left after suppuration. In other forms of scrofulous disease, in *chronic enlargements of the joints*, and *bone-affections* of such nature, iodine is often of great service. As scrofulosis is generally, if not always, associated with lowered nutrition and with anæmia, cod-liver oil and iron in some form should usually be administered as adjuvants. At the same time that the drug is exhibited internally in these cases, its ointment should be freely applied to the enlarged and indurated glands. Experience has demonstrated the value of iodine in *goitre*, whether of the ordinary variety or of that known as *exophthalmic goitre*, or *Graves's disease*. All tumors of the thyroid body are not goitre, however; cystic degeneration of it is very common, and is in no wise benefited by iodine. It is in simple hypertrophy of the gland that iodine used internally and applied externally over the tumor is beneficial. During the acute stage of enlargement the use of leeches is often of great benefit, and whenever much tenderness exists should precede the exhibition of the drug. In *phthisis*, iodine sometimes does good, but only in the most chronic cases; and inhalations of its vapors, as have been recommended by Piorry, can only be of service by stimulating the bronchial mucous membrane and the surfaces of cavities. When softening is progressing and the lung breaking down, iodine sometimes appears to hasten the process.

Local Application.—As a simple counter-irritant, iodine is very frequently employed when it is desired to maintain a mild, persistent influence, as in *chronic rheumatic affections* and sometimes in *phthisis*. For this purpose the tincture is generally preferred, and it should be applied freely once or twice a day, or every other day, according to the susceptibility of the patient's skin. In various affections of the skin, iodine has been employed with asserted advantage. In *erysipelas* of the skin, very beneficial results have been ascribed to its local use, and, I think, with justice; but great care is necessary lest it be applied too strong. I have seen very serious results from the destruction by it of the skin in this affection. If the full strength of the tincture be used, it should be applied at first very lightly, and not more than once in the twenty-four hours. In *psoriasis*, in *acne*, in *parasitic skin-diseases*, it has been used, but holds only a second rank among remedies. In a similar manner it is employed in various chronic diseases of the mucous membranes, such as *ozæna*, *leucorrhæa*, *chronic cystitis*, *chronic dysentery*, and *scrofu-*

lous ophthalmia,—whenever, in a word, an alterative, stimulant action is desired. In cases of *retraction of the gums*, with consequent loosening of the teeth, Professor Stillé recommends the application, with a camel's-hair brush, after each meal, of a watery solution (gr. i to f3i) of iodine, the mouth being immediately afterwards washed. The most important external use of iodine is as a resolvent in cases of indolent *glandular hypertrophic enlargement*, and where there are large watery exudations, as in some forms of *chronic pleurisy* and of *diseased joints*.

Iodine has been very largely employed by injection into serous cysts, as in *hydrocele*, for the purpose of exciting inflammation and causing obliteration of their cavity; but this use of it is purely surgical, and the reader is referred to treatises upon such subjects. In chronic *empyema*, the injection of iodine after free exit has been given to the pus is often of the greatest service. The solution in the beginning should be very weak, containing not more than six grains each of iodine and of iodide of potassium in a pint of water; with this the pleura should be daily washed out, the strength of the solution being gradually increased.

ADMINISTRATION.—Iodine is never administered in solid form; nor should the tincture be given internally, because the iodine is precipitated by the watery juices of the stomach. As the iodide of potassium holds the iodine in solution, this preparation may be freely diluted without precipitation, and may even be used hypodermically, as suggested by Professor Da Costa (*Amer. Journ. Med. Sci.*, Jan. 1875), in glandular enlargements. The dose is ten to fifteen drops well diluted.

The only preparation of iodine for internal use is *Liquor Iodi Compositus*—*Compound Solution of Iodine*—*Lugol's Solution*, U.S. (Iodine, 1 part; Iodide of potassium, 2 parts; Water, 17 parts),—dose, gtt. v. to xv.

For external use, there are a *tincture* (*Tinctura Iodi*, 7 per cent., U.S.) and an *ointment* (*Unguentum Iodi*: Iodine, 4 parts; Iodide of potassium, 1 part; to 100, U.S.).

Iodine has been used hypodermically, but usually produces so much local irritation as to forbid its employment; but, according to Dr. A. O. Squier (*Med. News*, lix., 1891), the following formula may be so used almost without pain: Eucalyptol, thirty-two minims; Guaiacol, pure, sixteen minims; Iodoform, eight grains; Iodine, four grains; Oil of sweet almonds, sterilized, q.s. ad one ounce. Dose, ten to thirty minims, hypodermically.

POTASSII IODIDUM—POTASSIUM IODIDE. U.S.

This salt occurs in white or colorless, generally cubic, crystals, soluble in 0.75 part of water and in eighteen parts of alcohol. If to its solution starch be added, no blue color should arise, but on the passage of chlorine the characteristic iodine reaction should take place, owing to the liberation of the metalloid by the gas; or if sulphuric acid be

added, a purple tint gradually appears, and deepens into blue: a spontaneous blue color betrays the presence of the iodate of potassium, a harmful adulteration. At a dull-red heat iodide of potassium fuses into a crystalline mass; by a bright heat it is decomposed.

PHYSIOLOGICAL ACTION.—Iodide of potassium influences nutrition in a manner similar to iodine: indeed, most authorities teach that their action is identical; yet in therapeutics they find a different range of employment, and, I believe, act differently. Dr. I. Wallace (*Liverpool Med. and Surg. Rep.*, 1871) has found that the iodide lessens the elimination of lime salts through the kidneys; but his analyses were not sufficiently repeated to prove that this is a constant effect.*

THERAPEUTICS.—In certain forms of *rheumatism*, iodide of potassium is of great value. In the early, active stages of *inflammatory rheumatism* it is useless; but later, when the joint-symptoms persist in a subacute form, the iodide comes very well into play. In *subacute* or *muscular rheumatism* the iodide is an efficient remedy. Often when the symptoms are very acute it may be advantageously combined with the alkalies, and in lingering cases, especially where there is reason to suspect a gouty taint, with colchicum. In *sciatica*, in *lumbago*, in *rheumatic neuralgia* following exposure to cold or wet, as in all other forms of subacute rheumatism, very much is to be hoped for from its use. In *gout* it is of less service than in rheumatism, but in the chronic form of the disease, and in the irregular, inherited gout which so frequently appears as neuralgia or other anomalous affection, it adds to the efficiency of small continuous doses of colchicum. In *rheumatic gout*, or *rheumatoid arthritis*, it should be tried; although little is to be hoped for from its use. There is a good deal of clinical testimony as to the value of iodide of potassium given continuously between the paroxysms of *asthma*. This disorder appears at times to bear a close relation to irregular gout or rheumatism, and it is probably under these circumstances that the remedy is efficient. In *tertiary syphilis*, including in the term all cases of syphilitic bone, visceral, or nervous disease, the remedy is really of inestimable value. It must be given freely, and, when there is no cachexia, may be advantageously combined with the bichloride of mercury. It is scarcely in place here to enumerate all the forms which tertiary syphilis may assume; but the iodide is useful wherever the dyscrasia has existed for a length of time.

The iodide of potassium appears to have the power of promoting absorption of serous fluids, and certainly is of value in *chronic pleuritis* with effusion, in *chronic pericarditis*, and even in *chronic hydrocephalus*.

In *aortic aneurism* large doses of iodide of potassium with continuous rest in the horizontal position have been used by Dr. Balfour (*Edinburgh*

* For a research upon the physiological action of large amounts of iodide of potassium injected into the blood, see *Arbeiten aus dem Pharmak. Laborator. zu Moskau*, t. 125. As it does not seem to throw much light upon the therapeutic use of the drug, it is not here analysed.

Med. Journ., xiii., xiv., xv., xvi.; *British Med. Journ.*, 1874, i. 112) with results that warrant a further trial. Dr. T. S. Sharpe has claimed success from its employment in chronic Bright's disease (*Amer. Journ. Med. Sci.*, Jan. 1876).

In various chronic *metallic poisonings* the iodide of potassium is of great service. With both lead and mercury it forms double salts, which are soluble, and there is very good reason for believing that the formation of these salts takes place in the economy, and that the metal which has been lying in an insoluble condition in the various tissues is taken up and excreted. Severe salivation and ulcerative stomatitis have sometimes resulted from the use of the potassium salt in those who had previously taken large quantities of mercury;* and in Melsen's experiments, dogs to which insoluble preparations of mercury had previously been given without the induction of severe symptoms afterwards died under the action of the iodide, the mercury also having appeared in their urine. The experiments of Mayençon and Bergeret, quoted in the article on Mercury, afford striking confirmation of these facts, and seem to render the evidence irresistible that the iodide does cause the elimination of mercury. In regard to lead, the researches of Drs. Parkes, Goolden, Swift, Melherbe, Sieveking,† and Marshall (*Therap. Gaz.*, Feb. 1888) have shown that very frequently in cases of chronic lead-poisoning the exhibition of iodide of potassium causes the appearance of lead in the urine. This chemical evidence is abundantly corroborated by clinical experience, so that in all cases of chronic metallic poisoning the persistent use of the iodide of potassium should be tried.

ADMINISTRATION.—The ordinary dose is ten grains three times a day; but much larger quantities may often be given with impunity, and, in internal syphilitic affections, may be necessary. In the latter class of diseases, the best plan is to begin with twenty grains three times a day, and rapidly to increase the amount until drachm doses are reached, or frontal pain or other symptom of iodism produced. The best substance for disguising the very disagreeable taste of the drug is the compound syrup of sarsaparilla. *Unguentum Potassii Iodidi*, U.S., contains twelve per cent. of the iodide.

LIQUOR ARSENI ET HYDRARGYRI IODIDI, U.S.—*Solution of Arsenic and Mercuric Iodide* contains one per cent. each of the iodide of arsenic and the red iodide of mercury. It was originally suggested by a surgeon of Dublin, by whose name it is very generally known. *Donovan's Solution* is a powerful alterative, used chiefly in very obstinate chronic scaly skin-diseases, when the local action is of a very low grade, and in chronic rheumatism. It is an exceedingly active preparation, very

* See Dr. Budd, *Brit. and For. Medico-Chir. Rev.*, xi. 202, for a striking case.

† See Sillé's *Therapeutics*, vol. ii. p. 735, Blanchard & Len, 1864.

capable of acting as a corrosive poison, and when administered a little too freely is said sometimes to cause salivation. When applied locally, it acts as a violent irritant. The dose of it is from three to ten drops, well diluted.

AMMONII IODIDUM—AMMONIUM IODIDE. U.S.

Ammonium iodide occurs in minute, colorless, cubical crystals, or as a white granular powder, hygroscopic, without odor when colorless, on exposure becoming yellowish, and emitting a slight odor of iodine, and having a sharp, saline taste. Ammonium iodide resembles closely, in its action, iodine and potassium iodide, and has been employed, both externally and internally, as a resolvent in *secondary syphilis, chronic rheumatism, incipient phthisis*, and in a variety of forms of *scrofulous disorder*, attended with glandular enlargements. The ointment (3ss to 3i to 3i) has been used in *lepra, psoriasis, scrofulous glands*, etc. As the iodide is decomposed by the air, the ointment should be kept in well-stopped bottles. For internal use the dose of ammonium iodide is from three to ten grains, in dilute solution.

STRONTII IODIDUM—STRONTIUM IODIDE. U.S.

Strontium iodide occurs in colorless, transparent, hexagonal plates, odorless, and having a bitterish, saline taste. It is deliquescent, and on exposure to air and light becomes yellow. It is soluble in 0.6 part of water at 15° C. (59° F.), and in 0.27 part of boiling water. This salt has been brought forward as a means of obtaining the alterative influence of an iodide without causing irritation of the intestinal tract or depression of the general nutrition. It contains about 56.5 per cent of iodine, and, although its actual value has scarcely as yet been made out, may be substituted for potassium iodide in various diseases. The dose is from five to ten grains, increased *pro re nata*. It is best administered in solution.

ODOFORMUM—IODOFORM. U.S.

This substance was discovered by Sérullas in 1822, and was introduced as a remedy by Dr. Glover in 1837, but did not become official until the 1880 revision of the U.S. Pharmacopœia. It occurs as small, pearly-yellow crystals, having a strong, persistent, saffron-like odor. Insoluble in water, but readily soluble in alcohol and in ether.

PHYSIOLOGICAL ACTION.—According to M. Maitre, when taken by man in doses of five or six grains iodoform causes no notable symptoms, but two hours after the drug has been ingested, iodine can be found in the urine. The extensive surgical use of iodoform has led to a number of poisonings by it. The symptoms are variously described, and it is almost certain that in some cases they have been due to the wound and not to the dressing. They may be preceded by general malaise for a day, and then suddenly burst forth (case, *Deutsch. Med. Wochenschr.*, ix. 443). In the most characteristic and severe class of cases the phe-

nomena resemble somewhat those of meningitis, and may be somnolence, deepening into stupor, with contracted motionless pupils, or restlessness, ending in active delirium, in either case the temperature being normal and the pulse exceedingly rapid. A peculiarity of these cases seems to be that death usually follows, although the symptoms have developed abruptly and the dressings have been removed at once. Dr. Schede, of Hamburg, describes six classes of cases, his sixth form being that just spoken of. 1. High fever, without other phenomena. 2. Fever, with mild gastro-intestinal irritation, depression of spirits, and rapid pulse; recovery almost invariable. 3. Very rapid, soft pulse, 150-180, no fever; great danger. 4. Very rapid pulse, with high fever; death almost invariable. 5. After severe operations, rapid collapse and death. A form of poisoning with melancholia, dilated pupils, and hallucinations is also described. A roseola-like dark-red eruption has been noted in some cases of poisoning, and even when the constitutional symptoms are very slight there may be an extensive erythema. (Cases, *Intern. Cong. Copenhagen*, 1884, Sect. Dermatol., p. 118.) In some cases of iodoform-poisoning convalescence has been very protracted, the patient remaining in a condition of unconsciousness or semi-consciousness for some days, with complete loss of memory and some evidences of mental disturbance. On account of the indefiniteness of the symptoms of iodoform-poisoning great importance attaches to any positive means of recognizing the nature of the illness. M. Burlureaux affirms that if a piece of silver be placed in the mouth of a person suffering from iodoform-intoxication, the taste of garlic will be immediately perceived, and that if some of the saliva be mixed with calomel, a canary-yellow precipitate of mercurial iodide will be obtained. These tests at most prove only that the patient is under the influence of some compound of iodine.

The action of iodoform upon the lower animals has been investigated by a number of observers, but to complete our knowledge further researches are necessary. The symptoms in the frog are said to be muscular relaxation with sometimes, at a later stage, convulsive movements. In the higher animals large but non-toxic doses produce symptoms of intoxication, tottering, weakness, and loss of appetite, but no vomiting; fatal doses cause anæsthesia, narcosis, convulsions, with violent opisthotonos, hurried or irregular breathing, slow, feeble pulse, and finally death. A. Hoyges found that in dogs and cats toxic doses caused deep sleep without loss of reflex activity, but that in rabbits no sleep resulted (*Arch. f. Exper. Pathol. u. Pharm.*, x. 405). Very frequently after these large doses, especially when they are repeated, there is great gastro-intestinal disturbance, as is shown by vomiting, diarrhœa, and dysentery, with bloody discharges. The action of the drug upon the circulation has been especially studied by M. Rummo (*Arch. de Physiol. Norm. et Pathol.*, 1883, 144). He finds that in the frog the rate of the cardiac pulsations is lessened, and for a time the energy of the ventric-

ular systole is increased, but afterwards the pulsations become feeble, and finally the heart is arrested in diastole; the contractions cannot be re-established by the use of atropine. In the mammal, the rate of the pulse is decreased, and after small doses the arterial pressure at first increased. By large doses the pressure is much diminished. Section of the pneumogastrics does not affect the cardiac action of the drug. M. Rummo finds that iodoform acts first upon the nerve-centres, and finally upon the trunks of the nerves and upon the muscles. After very large doses there is albuminuria and even hæmaturia.

After death from iodoform a very wide-spread fatty degeneration is to be found. This change appears to commence in the liver and rapidly to involve all tissues of the body. M. Floucaud (*Thèse de Montpellier*, 1872) states that there is a very distinct alteration of the blood-corpuscles.

By the alimentary canal iodoform is absorbed very slowly; from wounds it is taken up with comparative freedom. Zeller believes (*Zeitschrift für Physiolog. Chemie*, viii. 70) that there is always an albuminous compound of iodine formed at the seat of absorption. The iodine escapes from the body by all the secretions as well as by the breath, partially as an iodide, partially as an iodate, and partially in the form of a new organic compound of iodine.* According to the researches of M. Rummo, the elimination of iodine commences within one hour after the stomacheic ingestion of the iodoform, and goes on so slowly that the haloid can be found in the urine three days later.

It is probable, as Professor Binz teaches, that iodoform acts by liberating iodine in contact with the tissues, since Moeller has found that the iodates and iodic acid cause similar symptoms (*Inaug. Diss.*, Bonn, 1877), and Dr. Schwerin has shown that methyl iodide is also anæsthetic and hypnotic (*Centralbl. f. Med. Wissensch.*, 1884, 146).

When iodoform is applied in strong solution, or in substance, it acts as a very powerful local anæsthetic. Thus, a suppository containing it, if introduced into the rectum, will so benumb the parts that defecation may take place without the person or animal being aware of it.

THERAPEUTICS.—Iodoform has been used internally as an alterative and analgesic in syphilitic rheumatism and night-pains, and in other forms of neuralgia. Dr. Stiles Kennedy highly commends it (*Med. and Surg. Rep.*, Jan. 1870, p. 50), and Lazansky finds it very useful in some cases (*Centralbl. f. Chirurgie*, 1876, 219), but that it fails in others; he gives ninety grains a day. Dr. J. Moleschott (*Lond. Med. Record*, Nov. 1878) praises it most highly as an absorbefacient, affirming that by its use he

* For an important bibliography, see the paper of M. Rummo. For details as to elimination and discussion of methods of finding the iodine in the urine, consult Johannes Grundler, *Schmidt's Jahrb.*, ccl. 232; Professor Harnack, *Berlin. Klin. Wochenschr.*, 1883, No. 47, also *Zeits. f. Physiol. Chem.*, viii. 158, 1884; A. Zeller, *Arch. f. Klin. Chir.*, xxviii. 390; Dr. E. Baumann, *Schmidt's Jahrb.*, cclii. 233; *Verhandl. Deutsch. Gesell. f. Chemie*, Berlin, 1882, x. 219.

has obtained absorption of various lymphatic tumors, pleuritic, pericardiac, and other effusions, and has even cured acute *hydrocephalus* and *leukæmia*. He relies especially upon its external employment in the form of a collodion (1 part of iodoform, 15 of elastic collodion). As soon as the collodion has dried, he covers it with a film of solution of gutta-percha. Dr. Von Hoffer has used it hypodermically (three to five grains a day) in syphilis, and asserts that so employed it greatly increases the number of the red corpuscles. Dr. E. Thomaun also bears testimony to the value of these hypodermic injections in secondary syphilis (*Centralbl. f. Med. Wissen.*, Oct. 1881). Iodoform, however, has not come into general use as an internal medicine, and, in the extensive trials made with it at the Philadelphia Hospital, has failed to sustain its first reputation in syphilitic disorders.

Whatever position iodoform may finally acquire as an internal remedy, there can be no question as to its value when employed locally. It is useful in cases of painful ulcers, even when they are cancerous,* serving to alleviate pain and to promote cicatrization. At first employed especially in syphilitic affections, it is now found to act equally well in indolent leg-ulcers, in burns,† and other non-specific abrasions, and is thought to be not only a local anæsthetic, but also a decided stimulant to nutrition. Within the last few years it has been very freely employed as an antiseptic dressing to wounds, and the testimony is so strong that it is difficult to avoid believing that it is one of the most reliable of the antiseptics. It is, however, affirmed to have no power in preventing erysipelas, and used freely is very dangerous to the patients. It is employed either in the form of powder dusted in the wound, or as dressings saturated with it, the first method being at once the more effective and the more dangerous. The quantity required to take life is uncertain. Dr. Langenstein attributes a death to four grammes (*Wien. Med. Wochenschr.*, 1882, xxxii. 1051). The cause of death seems, however, doubtful. Dr. Czerny reports death from six grammes, not doubtful (*Ibid.*, p. 180).

In 1886, Fürst described furuncular and eczematous inflammation produced by the contact of iodoform with the skin. Dr. Krovat (*Therap. Monatsch.*, ii., 1888) affirms that this irritation can be rapidly relieved by momentary applications of very hot water to the part.

* Consult papers by Dr. G. Vélker (*Bulletin de Thérapeutique*, t. lxxiii., Dec. 1887) and Dr. Péreol (*Ibid.*, t. lxxiv., May, 1888). The surgical reader may consult with advantage the following additional references: *Corresp.-Blatt f. Schweiz. Aerts.*, 1882, xii. 609; *Deutsch. Med. Presse*, 1882, xxiii. 201.

† Burns, treatment of.—At a discussion of the International Congress of Dermatology, in 1889, the conclusion was reached that the best treatment of burns in the beginning is to cut the bullæ, wash the part with a very weak solution of salt, and then dress with iodoform gauze, or a pomade of iodoform, and cover with oil-silk. In the later stages, after the separation of the eschars, according to Hebra, iodoform retards cicatrization, whilst a one- or two-per-cent. solution of resorcin hastens epithelium formation.

The good results which have followed the surgical use of iodoform as an antiseptic dressing have led to a series of investigations as to its action on the lower organisms, with results which are apparently at variance with previous surgical teachings. In November, 1886, De Ruyter announced at a meeting of the Berlin Surgical Society that the powder of iodoform has little or no effect in preventing the development of bacteria, and that when it is mixed with rapidly-infective bacteria, like those of anthrax, it does not sensibly influence the development of the disease which is caused by inoculation with the mixture. This has been confirmed experimentally by Dr. Kronacher (*Münchener Med. Wochenschr.*, 1887, xxxiv. 546), who employed the bacteria of erysipelas and of anthrax; also by P. Baumgarten* (*Berlin. Klin. Wochenschr.*), who further found that iodoform powder mixed with the tubercular bacillus in cultivating apparatus did not prevent its ordinary development, and that the bacillus mixed with iodoform powder when introduced into guinea-pigs and rabbits produced rapid tuberculosis; also by Dr. Lübbert (*Fortschritte der Med.*, v. 343), with the *Staphylococcus pyogenes*; also by Drs. Chr. Heyn and Thorkil Drowsing (*Fortschritte der Med.*, v. 33), who found that iodoform has no influence upon the development of *Staphylococcus pyogenes* or of the coccus of pneumonia or of the *Bacillus subtilis* and other organisms, and conclude that it is not only worthless as an antiseptic but may even be the means of carrying the septic organisms into the system; also by Dr. Johan Olsen (*Norsk Magazin for Lægevidensk.*, 1886), with various bacterial organisms; also by Konige (*Therap. Monatshefte*, April, 1887). On the other hand, Dr. H. Sattler (*Fortschritte der Med.*, v. 362), in his experiments, found that when he impregnated threads with iodoform and micro-organisms and then placed them in culture-apparatus, the iodoform had a very distinct effect in checking the development of the bacteria, and De Ruyter states that if instead of using the iodoform powder he employed an ethereal solution in which decomposition of the iodoform had already commenced, there was a distinct effect upon the organisms. In a further series of experiments De Ruyter showed that iodoform is decomposed by blood, serum, and other organic fluids in which micro-organisms are growing, and apparently proved that the decomposition is produced by the ptomaines developed by the growing organisms. These general results have been abundantly confirmed:† the antiseptic properties of iodoform depend upon its decomposition, and its action is most favorable when the processes of fermentation and of chemical activity are most energetic.

The clinical results achieved by surgeons are so concordant and so decided that the practical value of iodoform in the treatment of wounds

* A curious fact made out by Baumgarten was that rubbing the bacillus of anthrax with any hard powder apparently mechanically kills the organism.

† See especially Neisser (*Virchow's Archiv*, Bd. cx.), Schnitzer (*Wien. Med. Presse*, cx., 1887), and Kuntz (*Beiträge Path. Anat. u. Physiolog.*, 1888, ii.).

and ulcers must be considered established. It is possible that a part of the good influence of the iodoform is due to a specific effect upon the tissues of the wounds. Further, the powder of iodoform may have a very distinct protecting power both mechanically and by the dryness of the wound which it maintains, the discharges from the wound being the especial soil in which the bacteria develop. In tubercular diseases iodoform appears to exert a direct influence upon the bacilli. Many clinicians bear strong testimony to the effect of iodoform on tubercular ulcers of the larynx and other organs. Professor Bruns (*Therap. Monatshefte*, May, 1887) relates fifty-four cases of cold tubercular abscesses treated by evacuation through aspiration and a subsequent injection of a ten-per-cent. mixture of iodoform, glycerin, and alcohol, with closure of the orifice made by the needle by means of the iodoform collodion. Of fifty-four such cases forty were healed,—many of them as the result of a single injection. For the purposes of study, some of the abscesses were opened, and tubercular bacilli were found abundant in their walls. According to Professor Bruns, the first change which results from the iodoform is the disappearance of the tubercular bacilli and the appearance of normal granular tissues. The value of iodoform as a local application in surgical tuberculosis seems to be firmly established. In the treatment of *tubercular abscesses*, in *tubercular empyema*, in *tubercular joints*, in *non-suppurating tuberculous glands*, and even in *tuberculous peritonitis*, numerous cures have been reported. That the iodoform has a specific influence upon the tubercular organism would seem to follow from the experiments of Gosselin, of Caen, who found that guinea-pigs saturated with iodoform are incapable of contracting tuberculosis. The manner of application varies with different surgeons. Verneuil, who has had an enormous experience, prefers, in the treatment of abscesses, tuberculous glands, and in most other cases, the injection of a five-per-cent. ethereal solution. Others prefer glycerin as a menstruum, especially in empyema; whilst others, particularly in peritonitis, dust the dry powder over the portion which has been laid open.

ADMINISTRATION.—Iodoform may be applied to ulcers in powder, in solution, or in ointment (*Unguentum Iodoformi*—10 per cent, U.S.). When there is a great deal of pain, especially if there be much discharge, the powder may be preferred. In my opinion not more than half a drachm of iodoform should be ordinarily applied to a wound, although in cases of tuberculosis the surgeon is more than warranted in taking the risk of larger amounts. Verneuil injects at one sitting never more than seventy-five grains of the iodoform. In *uterine cancer*, in *painful hemorrhoids*, cacao butter suppositories, containing from five to ten grains of the drug, may be employed. Owing to the bad odor of the drug, its application about the mouth and throat is often objected to. According to Dr. Lewis Elsberg (*Philad. Med. Times*, Oct. 4, 1873, vol. iv. p. 4), if to four parts of absolute ether one part of crystallized iodoform be

added, and the whole shaken in a red glass flask, a solution is obtained of sufficient strength for effectual use in diseases of the mouth, and free from odor other than that of ether. Olive oil, saturated with camphor, is said to dissolve six per cent. of iodoform, and is preferred by some surgeons.

In iodoform-poisoning there is no treatment other than meeting symptoms as they arise, unless, as is claimed by Samter and Retzlaff (*Therap. Gaz.*, 1889), the bromide of potassium acts as an antidote by virtue of its dissolving iodine compounds.

IODOL.

Iodol, which is made by the action of iodine upon pyrol, is a yellowish-brown, shining powder, composed of long, prismatic crystals soluble in three parts of absolute alcohol, in ether, and in fatty oils, but soluble in water only in the proportion of one to five thousand. It is tasteless and without odor. It contains 88.9 parts per hundred of iodine, as contrasted with 96.7 parts contained in iodoform. First discovered by Silber and Ciammican, it was proposed as an antiseptic by Dr. G. Mazzoni, of Rome (*Berlin. Klin. Wochenschr.*, 1885). The experiments made with it upon the lower animals by Dr. Marcus (*Berlin. Klin. Wochenschr.*, 1886) and by T. Pahl (*Inaug. Diss.*, Berlin, 1886) show that when given in sufficient dose to animals it causes emaciation, albuminous urine, fall of temperature, general loss of muscular power, and finally death from fatty degeneration of the liver, kidneys, and other tissues. It has been asserted by surgeons that iodol is not capable of producing constitutional symptoms. The experiments just quoted show, however, that this is not correct. Moreover, in a case reported by Dr. C. Lanenstein (*Therap. Gaz.*, 1887, 768, from the Swedish) the use of the drug as a surgical dressing caused dizziness, marked rise in the temperature, vomiting, small irregular pulse of 136, albuminous urine, and apathy, which did not subside for four days. Iodine was found in the urine for two weeks. In the experiments of Seifert, iodine was first detected in the urine and saliva twelve hours after the ingestion of seven and a half grains, did not reach its maximum until eighteen hours, and continued present for three full days: this accords with the statement of Pick (*Viertelj. f. Dermat. u. Syph.*, 1886) that iodol is absorbed very slowly. This slow absorption is probably the reason that it is a less dangerous topical application than is iodoform. Cervesato (*Berlin. Klin. Wochenschr.*, xxvi., 1889) affirms, with doubtful correctness, that in man iodol, taken internally, acts like preparations of iodine, but never causes iodism.

THERAPEUTIC USE.—Iodol may be employed for all purposes for which iodoform has been used. It has been found very valuable in the treatment of tubercular laryngitis, and may be blown into the larynx directly upon the ulcers without causing irritation. It has been used

by Pick very freely as a local application in the treatment of *blennorrhagic* and simple *vaginal catarrh*, as well as in *chancres* and other *ulcers*, and in *suppurative adenitis*. Various surgeons have employed it as a substitute for iodoform in the treatment of wounds, and the testimony as to its value is concordant. Mazzoni's original solution was—iodol 1 part; alcohol 16 parts; glycerin 34 parts. One drachm of iodol forms with one ounce of ether a clear brown solution, which may be applied by the spray or brush to the nasal and other mucous membranes, upon which it leaves a coating of iodol. Iodol pastilles are prepared by Dr. Wolfenden from one grain of iodol, one minim of glycerin, and eighteen grains of glyco-gelatin, and are by him strongly recommended for *laryngitis*. Iodol has also been used as an internal remedy. Dr. Assaky states that its effects in *tertiary syphilis* and *scrofulous affections* are extraordinary. The usual dose is two or three grains a day; but Assaky gave from six to thirty grains a day, and Pick asserts that he has given from thirty to forty-five grains a day, and that only in rare cases was there diarrhoea produced or any evidence of constitutional affection (*Therap. Monatshefte*, No. 1, 1887).

ARISTOL or Annidaline is a light, reddish-brown, odorless, crystalline powder, insoluble in water, very soluble in fats and ether, slightly soluble in alcohol. It is a substitution compound, having the chemical name *dithymol-diiodide*, and containing 45.8 per cent. of iodine. According to Neisser (*Berlin. Klin. Wochensch.*, xix., 1890) and to Quinquaud and Fournioux (*Compt.-Rend. Soc. de Biolog.*, 1890), and also to Eichhoff, when introduced even in very large amounts into mammals, it produces no serious intoxication. The method of its elimination has not been made out. Quinquaud and Fournioux recognized the presence of iodine in the urine of animals to whom it had been freely given, but were not able to discover traces of thymol. The experiments of Neisser seem to show that it has no influence upon the lower organisms, and it cannot be considered, therefore, as antiseptic. It has been employed by a number of practitioners with asserted good results as a local application in inflammations of the mucous membranes of the nose and upper air-passages, especially when there is absence of secretion; in *psoriasis*, in *lupus*, and in various *syphilitic lesions*, and as a substitute for iodoform in the treatment of wounds. It appears to be free from irritant properties, and may be used in a strength varying from ten per cent. to the pure powder.

DIODOPARAPHENOLSULPHURIC ACID.—Under the name of *Sozoiodol*, this acid has been put into commerce in various combinations; for the quicksilver salt, containing thirty-one and a half per cent. of mercury and thirty-eight per cent. of iodine, the improbable claim is made that it is almost as active as a germicide as corrosive sublimate, and is free from poisoning properties upon the human organism. See Dr. A. Lübbert (*Fortschritte der Medicin*, vol. vii., 1889).

OLEUM MORRHUÆ—COD-LIVER OIL. U.S.

Cod-liver oil is obtained from the liver of *Gadus morrhua* and other species of *Gadus*. In the manufacture of the so-called *shore oil*, the only variety usually employed in medicine, the fish caught near land are brought at once to the shore, and the oil is obtained from the fresh livers by one or other of several processes. The original custom was to put the livers into large kettles, add water, boil to a pulaceous mass, drain off the liquid, allow it to stand, and finally to skim the oil as it rose to the top. A more modern method is to heat the livers by steam applied to the outside of the vessel containing them, to allow drainage, and to proceed as in the process just described. I am informed that at present some of the finest brands of oil are prepared by forcing currents of steam at high pressure through the mass of livers, tearing them in this way to pieces, and melting out their oil. *Shore oil* should be a perfectly limpid, yellow, thick oil, free from rancidity, and having the peculiar taste and smell of the oil well developed. *Straits oil* or *Banks oil* is prepared from those fish caught at the "Banks," far from land.

The livers are thrown into casks and allowed to stand for a greater or less length of time and to undergo more or less complete putrefaction, until, on the return of the fishing-smack to port, they are thrown into water-boilers and treated in a manner similar to that previously described. Of straits oil there are two varieties: the *brown oil*, which is much darker than shore oil, and much more nauseous to the taste and smell; and the *black oil*, which is very dark, and still more disgusting in its evidences of rancidity. Both of these varieties are largely used in the preparation of leather.

When a mineral acid (especially the sulphuric) is added to cod-liver oil, the well-known biliary play of colors occurs; but this does not prove the genuineness of the drug, or demonstrate that it is derived from the codfish: it only shows that it is a *liver oil*. It is scarcely to be doubted that not rarely the livers of other fish are largely mixed with those of the *Gadus morrhua*, but it is not probable that this often happens to such an extent as to interfere with the therapeutic value of the product: indeed, it is far from certain that cod oil is really superior to that produced by the same organ of other fishes. Be this as it may, the physical properties afford the only known test as to the genuineness of the drug. Cod-liver oil is a very complex substance, containing, according to the analysis of De Jongh, glycerin, oleic, margaric, butyric, and acetic acids, gaduin, various biliary principles, such as fellic, cholic, and bilifellinic acids, iodine, chlorine, traces of bromine, phosphorus, phosphoric acid, and various other substances. According to the U.S. Dispensatory, the proportion of iodine never exceeds one part in two thousand. In De Jongh's analysis the greatest amount was found in the light-colored oils, and was only four-hundredths of a

grain in one hundred grains of the oil. *Gaduin* is a peculiar, dark-brown substance, which is probably medicinally inert. When to cod-liver oil ammonia is added, there can be obtained, by distillation, a peculiar ammoniacal base, *trimethylamin* (commercial *propylamin*), which exists in no other officinal oil, but occurs in the ergot.

PHYSIOLOGICAL ACTION.—As is well known, all fatty substances when taken into the system have a tendency to cause deposition or formation of fat in the body. Cod-liver oil certainly shares this property in an eminent degree. Dr. Pollock, as quoted by Professor Stillé, has found that if there be given of it to pigs from one to two ounces *per diem*, to sheep one ounce, and to bullocks from three to nine ounces, it is digested, and aids in fattening the animal; larger amounts than those noted in Dr. Pollock's experiments always derange very seriously the digestive function. No close studies of the effect of cod-liver oil upon healthy men have, that I am aware of, been made. Undoubtedly it tends to produce obesity; but, as no other oil is able to supply its place in various chronic diseases, it must have some influence upon nutrition not shared by ordinary fatty matters, and therefore is an *alterative*.

The history of the clinical use of *oleum morrhue* certainly indicates that it influences the constitution of the blood. It is an every-day occurrence to see pale, anæmic patients become, while taking it, rosy and plethoric. According to the analysis of the blood of a patient made by Simon, there is, during its use in phthisis, a great increase in the amount of solids in the blood, a diminution of the fibrin, and an increase in the albumen. The examinations of Dugald Campbell (*British and Foreign Med.-Chir. Review*, 1856, xvii. 21) have confirmed the results of Simon. It is very probable that cod-liver oil has some peculiar influence upon the blood-making organs. Upon the various single functions of the body, except the digestive, cod-liver oil has no apparent immediate effect, disturbing directly neither the nervous, motor, respiratory, circulatory, nor secretory movements. When by its use the general nutrition is improved, all the functions seem to share equally in the improvement. Cod-liver oil has undoubtedly, when given with sufficient freedom, a tendency to cause indigestion and looseness of the bowels. All oils are of difficult digestion, and when too much of the *oleum morrhue* is exhibited in man, as in animals, it exerts a deleterious local effect upon the alimentary apparatus.

Much speculation has been indulged in as to which of the ingredients of cod-liver oil impart to it its peculiar medicinal properties.* Cer-

* A. Gautier and J. Bouillot claim to have found in cod-liver oil certain alkaloids which are stimulants to the circulation and to the nutrition, and also to the kidneys, and to which is largely or altogether due the peculiar properties of the oil. These alkaloids have been used in practical medicine by J. Bouillot, who claims that 0.15 to 0.25 gm. given during the twenty-four hours powerfully stimulates nutrition, increasing very much the amount of the urine and also the nitrogenous elimination, especially of the completely oxidized nitrogen (*Compt.-Rend. Acad. Sci.*, cxv., 1892).

tainly, however, no conclusion has been established, and the present probabilities are that it acts as a whole,—i.e., that its virtues depend upon the peculiar combination.

If the experiments of Dr. Oswald Naumann (*Archiv der Heilkunde*, 1865, p. 536) be as accurate as they appear, he has certainly proved that cod-liver oil has physical properties which must aid in its usefulness, although it is not probable that its value depends solely, or even in great part, upon them. He first tested the rate at which various oils pass through fresh moist animal membranes when pressed upon by a column of mercury or by the weight of the atmosphere over an exhausted receiver, and found that cod-liver oil passed much more rapidly than any of a number of oils tried. Apparently this power depended in some measure upon the presence of the biliary principles, since if it was deprived of them the rate of its passage was greatly lessened, but was again increased by the addition of a little bile. The investigator then, opening the abdomen of cats, separated in each animal by ligatures two knuckles, of equal length and entirely similar, from the remainder of the intestines. Into each of them he injected a certain amount of bile, and then into one ordinary oil, into the other cod-liver oil; and when the animals died, some hours afterwards, it was always found that much more of the cod-liver oil was absorbed than of the other oil. These experiments were, unfortunately, too few and incomplete to be decisive, but certainly they indicate that oleum morrhue is more easily and rapidly absorbed than other animal oils. The superior fitness of the oil for absorption is in accord with the clinical observation of M. Berthé (*L'Union Méd.*, x., 1856), that cod-liver oil could be taken longer than other fats without appearing in the feces, and is confirmed by Professor Bucheim (*Arch. f. Exper. Path. u. Pharm.*, Bd. iii.), as well as by J. Gad (*His und Braune's Archiv für Anatomie*, 1878). Both Bucheim and Gad believe that this absorbability depends largely upon the presence of free fatty acids in the oil, but it is probably due to the biliary matters, since Dr. H. A. Hare finds it greatly increased by the addition of taurocholate and glycocholate of sodium (*Bost. Med. and Surg. Journ.*, cxvi. 279). He asserts that cod-liver oil impregnated with a small quantity of the biliary salts is rapidly absorbed when rubbed upon the skin, and proposes the practical use of the mixture.

Dr. Naumann's last series of experiments were directed to discovering the comparative ease with which animal oils and the cod-liver oil were oxidized. For this purpose he used a test-solution of permanganate of potassium, and on adding to given bulks of this, in test-tubes, equal amounts of the various oils, noted the changes of color induced by the reduction of the permanganate. He found that cod-liver oil was the first to be affected. It is evident that the power of being easily absorbed and easily oxidized fits a fat for use in the animal

economy; but the peculiar value of oleum morrhue does not depend solely upon these properties.*

THERAPEUTICS—Cod-liver oil is especially useful in that condition of system in which, with general lowered tone, there is a tendency to cellular hyperplasia, to the formation of "exudations" composed of imperfectly-developed cells, which, in the great majority of cases, from the very beginning are incapable of development into perfect entities, having only one potential quality, that of dying. There are various types of this diathesis, or condition of system. In one of them there is a tendency to increase in the lymphatic glands; to multiplication, at the expense of development, of their cellular elements,—i.e., to the formation of numerous imperfectly-developed cells,—and, finally, to the destruction of them. The death of these cells is partly due to their inherent qualities, and is partly the result of the pressure which they exert upon one another and upon their sources of food-supply. If they undergo a slow, fatty degeneration, with desiccation, cheesy deposits are formed; if a rapid, fatty change, with abundance of moisture, pus and abscesses are produced: in either case, ulceration is the final result. This is the so-called scrofulous diathesis,—*scrofulosis*. In another of this group of diatheses, the tendency to cellular hyperplasia affects the mucous membranes of the air-passages, and the patient, on the slightest provocation, suffers from catarrh, until finally a multiplication of cells occurs so rapidly as to fill up a greater or less number of the air-vesicles of the lungs, generally those of the apex, and "*consumption*" results; or else, an attack of pneumonia being produced by some exposure, the exudation is cellular rather than fibrinous, and catarrhal pneumonia, ending in the majority of cases in a more or less rapid phthisis, occurs.

As already stated, it is especially in these conditions of system that cod-liver oil is so extremely useful. Preceding the development of active disease in these cases there is very generally a recognizable stage, marked by weakness, a tendency to emaciation, more or less anemia, and other symptoms, which the present is scarcely the place to consider in detail. In this stage, cod-liver oil is exceedingly efficacious, and its use, combined with proper hygienic measures and the exhibition of other suitable drugs, may often succeed in warding off fatal disease. In *scrofulosis*, it is useful in all stages, but should never be relied on to the exclusion of other drugs. Its effects are more marked during the *ulcerative* and *suppurative stages*, but in most cases it aids iodine very materially to reduce the enlarged glands in the earlier periods of the disease.

* M. Chapoteau claims to have discovered a crystalline substance, *Morrhuel*, in cod-liver oil, containing phosphorus, iodine, and bromine. According to Dr. Lafage (*Le Progrès Méd.*, Feb. 20, 1886), to this substance are due the peculiar medicinal properties of cod-liver oil, and in tuberculous and allied diseases it may be given in capsules containing three to five drops, representing one drachm of cod-liver oil. *Morrhuel* is said to be stimulating rather than disturbing in its influence upon the gastro-intestinal tract.

There are various diseases of the bones, dependent upon or result from a scrofulous taint, which are most favorably affected by cod-liver oil. Sometimes the disease attacks the articulating surfaces, giving origin to chronic inflammations of the joints,—*white swellings*; sometimes it is the body of the bones, especially of such as are composed chiefly of spongy tissue, that is affected, and *caries*, with subsequent abscesses, results. In these, as in all other forms of scrofulosis, cod-liver oil is almost a specific. An affection probably not identical with, but closely allied to, scrofula, is *rickets*: cod-liver oil is of great value in this complaint. In certain pale cachectic children there may be found a swollen, tumid belly, perhaps with evident enlargement of the liver, and very generally, if not always, with enlargement of the mesenteric glands. This is the so-called *tubes mesenterica*, which is sometimes relieved, or even cured, by the exhibition of cod-liver oil.

The value of cod-liver oil in what is often very incorrectly called the "*pre-tubercular*" stage of phthisis has already been mentioned, but is so important that it will bear reiteration. There can be no doubt that consumption often commences with catarrh, and is often developed slowly as the result of frequently "catching cold." Whenever a patient is feeble, pale, somewhat anæmic, and complains of his liability to catch cold on the slightest exposure, even though no local disease exists anywhere, or rather because no local disease exists anywhere, there is cause for alarm; and it is of the most vital importance that the patient be put upon a tonic treatment whose basis is cod-liver oil, be fed upon nutritious diet, and have the hygiene of his daily life regulated, especial care being taken to avoid any exposure to cold. In the advanced stage of chronic *phthisis* the remedy is less efficacious, in that it much more rarely effects a cure than in the pre-tubercular stage; yet it does more good than all the other remedies of the Pharmacopœia combined,—alleviating the cough, increasing the strength, weight, and general health of the sufferer, often retarding or even arresting the pulmonic disorganization, almost always greatly prolonging life, and in rare instances, in conjunction with other measures, effecting a cure. It is a question of some importance to decide how the remedy does good in these cases. Its value, before the occurrence of any lesion, as a preventive of consumption, indicates that its influence during phthisis is not directly upon the local lesion, but upon the general condition of the system. This inference is borne out by clinical experience. The general symptoms commence to improve before the local lesions, and sometimes, although the patient fattens and gets stronger for a time, the pulmonic affection steadily increases; again, in some instances the oil fails to increase the weight of the patient or sensibly to affect the general nutrition, and in these cases it never does any good. In true *tuberculosis*, cod-liver oil, like all other remedies, is of very little, if any, value.

In cases of *defective nutrition*, when pallor, anæmia, loss of strength, and, perhaps, emaciation, occur without any obvious cause, cod-liver oil

is often of great service, especially when the subject is a child. Indeed, in children these symptoms are simply the result of a very mild action of the same depressing causes whose more intense malign influence produces scrofula.

In persons broken down with any of those chronic diseases which take the form of dyscrasia, the remedy is often of great service. Thus, in the cachexia of *tertiary syphilis* it is invaluable. The disease by whose relief and cure cod-liver oil first achieved its reputation is *chronic rheumatism*. I think, however, that it is much more efficacious in those cases in which the rheumatic disease has been grafted upon a scrofulously-tainted constitution, or in those cases in which the patient has been broken down by the disease, or by other agencies, so that there is what may be styled a general nutritive dyscrasia, than in simple chronic rheumatism; yet in obstinate *sciatica* and *lumbago* trial of it should always be made. In *gout*, *oleum morrhue* is of little service, and should be used only in the very chronic form of the disease, and when there is a generally disordered nutrition.

In *nervous affections*, especially in *neuralgia*, in *skin-diseases*, in fact, in any chronic disorder in which the patient is feeble and presents a condition of general depraved nutrition somewhat similar to that seen in consumption, cod-liver oil may be exhibited with advantage.

ADMINISTRATION.—The dark oil has been esteemed most highly by some authorities, especially by De Jongh, who asserts that it contains more of the biliary principles than does the pale oil, and even believes that the products of decomposition in it increase its beneficial action. It is, however, never employed at present, because of its exceedingly repulsive taste, and because it is very prone to disagree with the stomach. One of the difficulties in the use of even the pale oil is the very common real or imagined inability of the patient to take it. Without doubt, this very often arises from its nauseous taste, to lessen or disguise which various expedients are resorted to, with more or less doubtful success. Sometimes a piece of salt taken into the mouth just before the oil, which is also immediately followed by another lump of salt, suffices. It is said that some prefer the oil in emulsion made with some strong aromatic water. The addition of an equal part of glycerin and one-half to one drop of the oil of bitter almonds to the dose certainly lessens the taste of the medicine. Some patients take it best in the froth of ale or porter, the glass being first half filled with the malt liquor, then the oil being carefully floated on the top without touching the sides of the glass, and the remainder of the vehicle put upon the top of it. Most of the patients requiring oil are also benefited by the use of alcohol; and my experience with the remedy is that the most generally successful plan of exhibition is to place, according to the exigencies of the case, from one to three tablespoonfuls of whisky or brandy in a tumbler, add not so much water, put the oil in the centre, and toss the whole down the throat, the head being held well back, the

mouth wide open, and the lips not touched by the medicine. The stimulus of the alcohol often enables the stomach to digest the oil when otherwise it could not do so. Sometimes it is necessary to commence with a single small daily dose, even a single teaspoonful, which is best taken at bedtime, and gradually to increase the amount as the patient becomes habituated to it. Children almost always learn to tolerate the taste of the oil, or even become in a short time fond of it. The usual dose is for an adult a tablespoonful three or four times a day; for a child one year old, a teaspoonful. When infants cannot digest cod-liver oil, inunctions may sometimes be practised with advantage. Drs. N. A. Randolph and A. E. Roussel state that they have seen in such cases the oil appear in the *stercora* (*Phil. Med. Times*, xiv. 239).

ACIDUM PHOSPHORICUM—PHOSPHORIC ACID. U.S.

Phosphoric acid, which results from the burning of phosphorus in the air, is prepared by the action of sulphuric acid upon bone-ash, which consists chiefly of calcium phosphate. The official acid is the tribasic acid of chemists. *Acidum Phosphoricum Dilutum*, U.S., contains ten per cent. by weight of absolute ortho-phosphoric acid. It is a colorless, inodorous, sour liquid, of a syrupy consistence, which has a very acid reaction, but is not corrosive to animal tissues. The bibasic pyrophosphoric acid is said to be a cardiac sedative (*Journ. of Anat. and Physiol.*, xi.).

THERAPEUTICS.—Phosphoric acid has been used to a considerable extent abroad as a tonic and alterative in *scrofulous affections*. Upon the digestive organs, in my experience, it has little effect, and I have never been able to perceive that it is an astringent or an alterative to the alimentary glands. In *scrofulosis* and rickets it is, I think, inferior to the phosphates. Dose, five to fifteen drops, diluted.

PHOSPHATE OF CALCIUM.—The phosphate of calcium is, as is well known, an essential ingredient of bone, of which, indeed, according to the analysis of Berzelius, it forms more than fifty per cent. (*Traité de Chimie*, Paris, 1833). It should not be forgotten, however, that it exists in notable quantities in all the tissues, and is probably as essential an ingredient of their structure as of that of bone. Whenever it is taken out of the food of animals, although they be otherwise well fed, sooner or later they waste, sicken, and die. Chossat fed pigeons exclusively on corn containing very little of the phosphate of calcium, and found that after some months they wasted, were affected with diarrhoea, and died (*Comptes-Rendus*, t. xiv.). According to Roloff (*Virchow's Archiv*, Bd. xlv. p. 302), a herd of cows which had been fed upon hay from a certain meadow were very much out of health, and suffered from *fragilitas ossium*. On examination, the hay was found to be nearly free from earthy salts, and upon bone-meal being given to the cows they recovered their health in four weeks. The same authority further

states that, in some meadows with which he is acquainted, the disease is endemic among the cows because the grass is so poor in phosphates. Haubner also affirms (*Schmidt's Jahrb.*, Bd. cli. p. 138) that cattle fed exclusively upon potatoes, or upon roots very poor in phosphates, fail to fatten, become weak, and are apt to suffer from caries, but that if the phosphate of calcium be given they rapidly improve; and E. Voit (*Zeitschr. f. Biologie*, xvi. 198) states that rachitis without emaciation can be produced in three or four weeks in young dogs by taking the phosphate of calcium out of the food. Hegar (*Schmidt's Jahrb.*, Bd. cli. p. 138) has considered the absorption of the phosphate of calcium, when given as a medicine, very doubtful, because when he exhibited it freely there was no increase in the amount of the phosphoric acid or of the earthy bases in the urine. Böker (*Ibid.*), on the other hand, has found that if the drug be given to those wet-nurses whose milk contains an abnormally small amount of phosphates, the milk soon becomes rich in the earthy salts, and L. Perl (*Virchow's Archiv*, lxxiv. 54) has found that administration of the phosphates is followed by an increase in their amount in the urine. Further, Albert Riesell (*Hoppe-Seyler's Medicin.-chem. Untersuch.*, p. 318) has shown that the phosphates are eliminated by the intestines, and therefore that even if it were a constant fact that their renal excretion is not augmented by their administration, it would not prove that they are not absorbed. M. Teissier has found that in the early stages of phthisis there is a very great increase in the excretion of the earthy phosphates by the kidney (*Le Mouvement Méd.*, Sept. 1875), and the researches of Professor Beneke* (*Schmidt's Jahrb.*, Bd. cli. p. 138) are said to have shown that this increased renal elimination, which plainly occurs in several allied diseases, is not accompanied by any increase in the amount ingested in the food, or decrease of the amount eliminated by the intestines, and that, consequently, there is a very decided wasting of the normal phosphates of the body. This being so, the use of phosphates in these diseases is as rational as that of iron in anemia.

THERAPEUTICS.—According to Dusart (*Archives Gén.*, 6e sér., t. xv.), to Beneke (*loc. cit.*), and to Teissier (*loc. cit.*), the diseases in which the phosphate of calcium is especially indicated are rachitis, osteomalacia, phthisis, and scrofulosis. It is evident that the indications for the earthy salts are very strong in the first two of these affections; and clinical experience has certainly borne out the results of a priori reasoning. In scrofulosis, the call for the drug is not so plain; but Professor Beneke states that in many cases, if the urine be examined, it will be found to be abnormally rich in earthy phosphates, and that under these circumstances the remedy is of the greatest value. Cases are not rare of children of slow development, often seemingly well nourished and ro-

* I have not had access to the original memoir of Beneke, *Zur Würdigung des Phosphors Kalkes in physiolog. und therapeut. Beziehung*, Marburg, 1870.

bust, and yet really pale and with flabby flesh, but without any distinct symptoms or marks of scrofulosis or of rachitis. Under these circumstances, the child is in a condition allied to that of the diathesis spoken of, and of the value of the phosphate of calcium I have no doubt. In cases of *delayed union after fracture*, the present remedy is seemingly indicated, especially since Dusart (*loc. cit.*) has experimentally proved that when given to animals whose bones have been broken it hastens union and makes the callus abnormally heavy and firm. The phosphate of calcium has been recommended in various diseases other than those mentioned, but its value is much more doubtful. Bennett commends it in *chronic phthisis*; Piorry (*Journ. de Chim. Méd.*, t. ix., 1863), in *syphilitic periostitis*; Beneke, in *syphilitic gummata*; Schönian, and also Kugelmann, in the *menorrhagia* of anæmic women. Professor Beneke calls attention to the use of it during *pregnancy*, and believes that it exerts an influence on the foetus, so that women who have borne, it may be, only rachitic or scrofulous children will bring forth healthy offspring.

ADMINISTRATION.—The U.S. Pharmacopœia recognizes the *Precipitated Calcium Phosphate* (*Calcii Phosphas Precipitatus*), a white, inodorous, tasteless powder, which is prepared by dissolving bone-ash in muriatic acid and precipitating with ammonia. This may be employed in doses of ten grains three or four times a day, but, owing to its insolubility, is not so useful as the so-called *lacto-phosphate of lime*. This preparation, originally suggested by Dusart and Blache (*Archives Gén.*, t. xv. p. 67), is made by the action of lactic acid upon the phosphate of calcium, and was found by those experimenters to be soluble in all proportions not only in water but also in the gastric juice. There is prepared by the druggists in this city an emulsion containing fifty per cent. of cod-liver oil and two grains of the lacto-phosphate of lime to the drachm, which has appeared to me to be the best of all the alternative preparations in cases of the character spoken of in the section on therapeutics. It certainly is very often more easily digested than the pure oil. The dose is a teaspoonful to a tablespoonful, or even more, according to the age.

Under the name of *chemical food*, or *compound syrup of the phosphates*, a very complex preparation has been much used in disorders attended with impaired nutrition, such as the lacto-phosphate of lime has been recommended in. I have had no experience with it, but very much doubt its being superior, or even equal, to the latter drug.

COLCHICI SEMEN—COLCHICUM SEED. U.S.
COLCHICI RADIX—COLCHICUM ROOT. U.S.

Colchicum autumnale, or *meadow saffron*, whose products the above drugs are, is a little plant growing in Continental Europe and in England. It is not really the root that is officinal under the name of *colchicum root*, but the thickened swollen end of the stem, with the little bulblet

whose office it is to develop a new plant. This *corm* is solid and fleshy, an inch and a half to two and a half inches in length, with a longitudinal groove, having a nail-like process (the *bulblet*) at its base. In the shops it is very commonly kept in transverse slices, which are notched and cordate; the taste is bitter, hot, and acrid. Colchicum seeds are nearly round, about an eighth of an inch in diameter, and of a bitter, acrid taste. The active principle of both seed and corm is an alkaloid, *Colchicine*, whose individuality was first made out by Geiger and Hesse. According to Hübler, it is slowly soluble in water, readily so in alcohol, and not at all so in ether: with concentrated nitric acid it makes a violet solution, which when diluted with water becomes yellow; with concentrated sulphuric acid it strikes an intense yellow. By the action of mineral acids and by other agencies it is resolved into a brownish-green insoluble resin and a crystallizable neutral substance, soluble in water, *Colchicine*.

PHYSIOLOGICAL ACTION.—When taken in dose of sufficient size, colchicum acts upon man as a poison, producing repeated, uncontrollable vomiting, with nausea and retching, and also violent purging, at first of serous character; afterwards the passages become smaller, more mucous, with flakes in them, and finally in some cases bloody. Abdominal pain may be absent or present, but if present is generally griping; sometimes there is gastric burning. Nervous symptoms have been prominent in some of the severe cases. In one instance, it is said, a feeling of numbness or prickling was complained of by the patient; but this seems not to be common. Spasms are very frequent, and sometimes convulsions, which may be fatal, are present. Muscular pains are not rarely experienced, in some cases replacing the spasms, and probably in all other cases coincident with them is great muscular weakness, amounting, as death approaches, to paralysis. Finally, a condition of collapse develops itself, the circulation fails more and more, the pulse, which has been frequent and feeble, becomes rapid and thready, the skin cold, pale, or livid, and bedewed with sweat, and death from exhaustion results. Consciousness is preserved until the last. The effect of lethal doses of colchicum on the urinary secretion varies: sometimes the kidneys seem to be nearly unaffected almost to the last; sometimes their functional activity is decidedly increased, but in other cases it is diminished, and even suppression of urine has been noted. The symptoms produced by the largest therapeutic doses of colchicum are slowing of the pulse, nausea, vomiting, abdominal uneasiness, borborygmi, and free purging, together with a sense of prostration and of weakness. The occurrence of the inflammatory changes after the hypodermic injection of colchicine proves that the irritant principle of colchicum acts by absorption, and that the intestinal symptoms are not simply due to a local action,—deductions confirmed by the chemical experiments of Asehoff, who found colchicine in the liver, kidneys, heart, lungs, and blood of a rabbit poisoned with one and a half grains of it.

Upon most animals colchicum acts very much as it does upon man, in poisonous doses producing, as prominent symptoms, severe and often bloody purging, vomiting, great prostration, embarrassed respiration, finally more or less pronounced paralysis, and death, not rarely preceded by convulsions. Reflex actions are lessened, and finally abolished (Albers, Rossbach), in the frog; but Rossbach affirms that there is a precedent stage of convulsions with excessive reflex activity; in warm-blooded animals this first stage of excitement is rarely, if ever, seen. According to the elaborate experiments of Rossbach, the motor nerves and the striated muscles are not affected by the poison, but the higher nerve-centres, the spinal cord, and the peripheral sensory nerves suffer palsy. The same observer found that the circulation was very little influenced, that the pneumogastrics were not affected until near death, and that the splanchnic and intestinal vagi escaped altogether. In no case do reflex spinal convulsions occur at any time.

Using Merek's colchicine in the laboratory of the University of Pennsylvania (*University Medical Magazine*, vol. i.), Adolfo Ferrer y Leon confirmed the results of Rossbach, that the alkaloid has very little influence upon the circulation, although when the dose was sufficiently large there was some cardiac depression. He also noted that the sensory nerves were especially affected. Jacobi (*Sajous Annual*, 1891) affirms that absolutely pure colchicine is physiologically inert, but that it is transformed in the system into a brown, amorphous, oxidation product, *oxydicolchicine*, which produces the poisoning symptoms commonly attributed to colchicine. He confirms the conclusion of Rossbach, that there is paralysis of the motor-cord, and believes that death is usually due to centric respiratory paralysis.

The outcome of our present physiological knowledge seems to be that colchicine, in toxic dose, paralyzes the peripheral sensory nerves and finally the motor tract of the cord with the respiratory centre, and has very little action upon the circulation. On the other hand, as was first pointed out by Schroff, and since confirmed by Rossbach (*Pharmak. Untersuch.*, Bd. ii.), the rapidity of death in colchicine-poisoning is not at all in proportion to the size of the dose. Thus, Schroff noticed that one and a half grains of colchicine produced death in the rabbit in fourteen hours, whilst fifteen grains killed in eleven hours. This failure of relation seems to be explicable only by the supposition that colchicine kills chiefly by its irritant action on the alimentary canal, and, not being in any dose corrosive, requires time to work out the fatal result, through the instrumentality of a gastro-enteritis. This deduction is confirmed by the long-protracted course of the poisoning after small doses. Thus, Aschoff noted death on the ninth day in a pigeon which had received one-fourth of a grain of the alkaloid.

After death from colchicum, the blood is generally found very dark and imperfectly coagulable; but whether this is due to a direct action

of the poison, or is the result of the slow death by asphyxia and exhaustion, has not been determined. The chief changes are, however, in the alimentary canal, the mucous membrane of which is much swollen, intensely congested, sometimes ecchymotic, or with blood free in the intestine.

Geiger (*Annal. Chem. Pharm.*, vii. 274), Hoppe, Aschoff (*Vierteljahresschrift für Prakt. Pharm.*, vi.), Schroff (*Oester. Zeitschrift f. Prakt. Heilk.*, 1856), and Albers (*Deutsche Klinik*, 1856, xxxvi.) have experimented with colchicine, and have shown that it causes symptoms similar to those produced by colchicum,* of which it is without doubt the active principle. The closer studies of Schaitanoff, Rossbach, and Paschkis (*Schmidt's Jahrb.*, cci. 232) appear to have yielded contradictory results. Schaitanoff and Paschkis found that the alkaloid notably increases the arterial pressure; Rossbach, that the circulation is but little affected; while in Rossbach's experiments there was a narcosis which seems to have been replaced in the experiments of Paschkis by a peculiar loss of sensibility. The last observer noted also that neither the vagi nor the splanchnics were affected. All observers appear to agree in stating† that the chief force of the poison is expended upon the alimentary canal, at least in mammals, and that after death, even when the alkaloid has been given hypodermically, the intestinal mucous membrane is found much inflamed, as is also very frequently the inner coat of the stomach. Paschkis has found that the normal excitability of intestinal peristalsis by galvanization of the pneumogastric nerve is destroyed by colchicine.

The action of poisonous doses (one to two grains) of colchicine has been studied upon dogs by Dr. Samuel R. Percy. The symptoms are very similar to those produced by colchicine; they are—increase in the frequency of the pulse, severe purging with tenesmus, vomiting, finally great slowing of the pulse and failure of the heart's action, and death without convulsions. The urine, at first increased, was afterwards suppressed. On post-mortem examination, the mucous membrane of the intestines was found highly inflamed, that of the stomach slightly so, and the heart and arteries were filled with black tarry blood, similar to that of colchicine-poisoning. On the other hand, Paschkis asserts that one and a half grains of colchicine injected into the jugular vein of a dog produced no results whatever. It is evident that the two experimenters had different substances. Ferrer (*University Med. Mag.*, vol i) finds that colchicine acts chiefly upon the motor, and not, as does colchicum, upon the sensory nerves, and that whilst it stimulates the peripheral vagi, it does not depress the heart-muscle.

* Dr. R. Lewins's experiments (*Edinb. Med. and Surg. Journ.*, vol. lvi., 1841) may be employed for comparison. He used colchicum.

† Unfortunately, the works of nearly all these investigators are known to me only at second-hand. Not having had access to the original papers, I have been forced to depend upon abstracts in various journals.

The main interest to the therapist in the physiological study of colchicum, of course, is in regard to its action in small therapeutic doses. The most prominent result of the ingestion of such amounts is gastro-intestinal disturbance, as shown by abdominal uneasiness, colicky pains, borborygmi, loss of appetite, moderate purging, and sometimes nausea,—symptoms differing in degree only from those of poisoning by the drug. Before they come on, however, there is a lowering of the pulse-rate, sometimes as much as twelve beats per minute. Upon the skin the medicine occasionally acts, producing in some cases *diaphoresis*, and it is said that the amount of this action is in inverse ratio to the effect on the bowels. According to Schroff, the one-hundredth of a grain of *colchicine** is rather more than the therapeutic dose, and produces purging, lasting for several days, with griping pains, cerebral distress, a pulse at first lowered but afterwards accelerated, and a secretion of thick lateritious urine. Any nervous symptoms, such as vertigo, headache, muscular weakness, which may be present as the result of the administration of colchicum, are probably sympathetic upon the gastro-intestinal irritation. It is evident that colchicum influences the bowels powerfully, and probably in this way acts as an eliminative. But in the minute doses often used with advantage in disease, purging does not occur, and consequently increased elimination, if it takes place, must be through the kidneys: great interest therefore attaches to the influence of the remedy upon the urinary secretion. In considering this, the effects of poisonous and of therapeutic doses must not be confounded, for it is very evident that an irritation which causes suppression of urine may, when present in a much milder degree, produce an increased flow.

It seems very certain that in moderate doses, repeated at regular intervals, colchicum very often increases the flow of urine. In 1828, Chelius announced that during its administration in gout the amount of uric acid eliminated is nearly doubled. Dr. R. Lewins (*Edinburgh Medical and Surgical Journal*, 1841, vol. lvi. p. 200) submitted the urine of several persons suffering from gout, taken before and after the administration of colchicum, to Professor Christison, who found in the

* Drs. Malet and Combemale (*Comptes-Rendus*, civ. 515) have made a series of experiments to determine the dose of colchicine. They find that if given by the stomach it causes when in the dose of 0.0002 gramme per kilogramme in the lower animals no diarrhoea, but polyuria; of 0.00025 gramme per kilogramme, violent purgation, with a little general depression; of 0.000476 gramme per kilogramme, violent bloody diarrhoea, with salivation, polyuria and great feebleness, lessening of the temperature, and rapid respiration. Given hypodermically, the diuretic dose is 0.00015 gramme, the purgative dose 0.00025 gramme, and the toxic dose 0.00035 gramme, per kilogramme. When given to the healthy man by the mouth it produces in doses of 0.0002 to 0.003 gramme mild headache, muscular weakness, abdominal pains, increased frequency of the pulse, thirst, increased diuresis; in doses of 0.005 gramme, diarrhoea and diminution of the urine. In experiments upon two gouty individuals under the influence of a purgative dose of colchicine (0.0005 gramme) the urine was lessened in quantity, as was also the elimination of urea, but the elimination of uric acid was distinctly increased.

colchicum-urine the *proportion* of urea nearly double, and that of uric acid greater* than, that of the other specimens.

In 1852 Dr. MacLagan (*Edinburgh Journ. Med. Sci.*, 3d series, vol. xiv. p. 24) analyzed the urine of three cases of rheumatism before and after the exhibition of colchicum: in two instances the *proportion* of urea was very greatly increased, that of uric acid slightly so. In the third case the effect just noted happened at first, but not afterwards.

On the other hand, Professor Stillé states that Graves and Gardner affirm that the urates diminish under the use of the medicine. It is evident that these different results are not so contradictory as they seem, for it is possible that in one case the colchicum may so act as to increase the elimination of urea, in another that of uric acid, and that when one of these is increased the other may be unaffected, or even diminished.

Further, when the medicine purges freely it is very probable that elimination by the kidneys is lessened; and no account of this is taken by any of the observers whose original papers I have seen. Moreover, these observers also all contented themselves with noting the *proportion* of urea and uric acid in the urine, when it is evident that the mere *proportion*, unchecked by the absolute amount of urine secreted during the twenty-four hours, is no criterion as to the absolute amount eliminated. Dr. A. B. Garrod (*Med.-Chir. Trans.*, 1858, xli. 348) has made a study of the subject in such a way as to avoid this fallacy, and found that the elimination of urea and uric acid was sometimes increased, but that, on the whole, no marked effect was produced. Dr. Noel Patton (*British Med. Journ.*, i., 1886) states that in his experiments on dogs small doses of colchicum increased very distinctly the elimination of urea and uric acid, as well as the amount of the urine; while large doses lessened the amount of urinary secretion and increased slightly the daily elimination of urea and uric acid. He believes that the increase was due to an increased production, because after the administration of the drug the daily elimination did not fall below the norm. I do not think, however, that at present we are warranted in considering it established that colchicum materially influences nitrogenous elimination.

The action of the drug upon the urine during health is evidently very closely connected with the question just discussed. Here again we find conflicting and insufficient testimony. Dr. Bird (*Urinary Deposits*, Phila., 1859, p. 354) quotes Professor Kramer's† experiments as showing that colchicum does not increase the amount of solids eliminated, and intimates that his own investigations had given similar

* Dr. Harley (*The Urine and its Derangements*, Phila., 1872, p. 81) makes the assertion that colchicum diminishes the excretion of uric acid and even the urea: as, however, he does not deem it necessary to give any authority for the assertion, and as he does not appear to have made any elaborate chemical examination himself, not much weight is to be attached to his testimony.

† Kramer's paper was published in *Keller's Archives*, Dec. 1847, and is inaccessible to me.

results. Dr. Hammond (*Proc. Phil. Acad. Nat. Sci.*, Dec. 1858), on the other hand, in a series of experiments in which every care to avoid fallacies, by maintaining equality as to diet and exercise, was observed, found that while squill and digitalis only increased the watery part of the urine, both the organic and the inorganic solids were remarkably increased by colchicum.

In regard to *colchicine*, the experiments of Professor S. R. Percy (*Amer. Med. Times*, April, 1862, p. 167) indicate, but are much too few to prove, that in gout it increases the elimination of urea and uric acid.

THERAPEUTICS.—Our knowledge of the use of colchicum in disease is purely empirical, based upon clinical experience; and our acquaintance with its physiological action is not sufficient to enable us even to explain fully what experience has taught, much less to guide us in our use of the drug. *Gout* is the one disease in which colchicum is almost universally recognized as a specific. It may be advantageously employed both as a preventive of the paroxysm and to lessen its severity when developed. During an attack of gout, from ten to twenty drops of the wine of colchicum root may be exhibited every four hours until some decided evidence of its action, such as nausea or slight purging, is induced. It should always be borne in mind that although looseness of the bowels may be useful, yet when colchicum purges the gouty patient actively it mostly fails in achieving the desired therapeutic result. Its action is most favorable when its influence is felt chiefly upon the skin and the kidneys. To effect this desired result, it is often well to restrain the tendency of the drug to act upon the bowels, by combining it with opium. This is especially the case in debilitated subjects, in whom anything like over-purgation must be avoided with the most scrupulous care. By large purgative doses of colchicum the paroxysm of gout may often be suppressed; but experience has shown that this use of colchicum is dangerous, the suppression being sometimes followed by serious internal disease, apparently due to a transfer of the gouty irritation. Between the paroxysms, colchicum may be steadily exhibited to the gouty subject in small doses (ten drops of the wine of the root three times a day); and often great advantage is derived from its combination with iodide of potassium. This combination is especially useful in irregular atonic gout, such as is most frequently seen in women of feeble nervous organization who have inherited the diathesis, but is sometimes present even in robust men. Ten grains of the iodide and ten drops of the colchicum wine may be given three times a day. Speculations as to how colchicum cures gout appear to me useless in the present state of our knowledge: until we know more of the physiological action of the drug and of the nature of the disease, one theory seems as good as another.

In *rheumatism*, colchicum has been highly recommended by some, but has never come into such general use as in gout. In the inflammatory variety of the disease it is of but little value, except in purgative

doses, and is mostly administered in the form of *Scudamore's Mixture*, which is composed of magnesia and its sulphate with wine of colchicum root. In *subacute rheumatism*, the combination of colchicum and iodide of potassium, already spoken of, is very useful.

Colchicum has been administered in various diseases, but when there is no rheumatic or gouty taint is at present very rarely used.

Toxicology.—The symptoms of poisoning by colchicum have been already enumerated. The fatal dose varies, but is small. Professor Geo. B. Wood (*U.S. Dispensatory*, 13th ed., p. 1504) states that death has been produced by two drachms and a half of the wine of colchicum root; and Taylor (*Medical Jurisprudence*, 2d ed., vol. i.) records a case in which three drachms and a half proved fatal. On the other hand, recovery has taken place after the ingestion of an ounce.* According to the experiments of Schrott, *colchicine* is eighty to one hundred times stronger than the fresh corm. According to Heinrich,† 0.15 grain of *colchicine* will produce poisonous symptoms in man, and in Krahmer's experiments (*Journal für Pharmakodynamik*, ii. 561) 0.3 grain caused in an adult violent serous purging, lasting for four days, and accompanied with severe tenesmus. Casper has seen death result from a quantity of the wine containing 0.025 to 0.03 gramme (0.37 to 0.45 grain) of *colchicine*; but, according to Husemann, recovery has taken place after the ingestion of 0.045 gramme of the alkaloid. Dr. Geo. W. Major (*Canada Med. and Surg. Journ.*, Dec. 1873) records seventeen cases of poisoning from one bottle of wine of colchicum seeds occurring in Montreal, seven of which proved fatal. The patients had been vomiting and purging almost continuously for many hours when first seen, and the symptoms were exactly those of the stage of collapse of severe cholera morbus. In no case was the purging bloody. Consciousness was preserved to the last, and in only one case was there anything like convulsions. There was decided numbness of the extremities; and a peculiar hoarseness of the voice was especially noted.

The treatment of colchicum-poisoning is as follows. If the stomach and bowels have not been freely evacuated, administer at once an emetic and a cathartic, so as to empty the alimentary canal; allow the patient to drink freely of warm water, to aid in these operations and to act on the kidneys. Give freely of tannic acid, as the only known chemical antidote; although experiments upon animals have shown that it is not to be relied upon. To check the vomiting and purging, administer opium freely; and to allay the irritation, cause the patient to drink freely of albuminous matter, such as white of egg dissolved in water: the tannic acid having been given as soon as possible after the taking of the poison, the demulcents are useful in the more ad-

* See case in *L'Union Médicale*, Aug. 1848.

† Quoted by Husemann.

vanced stages. Symptoms of gastro-enteritis or of collapse are to be met as they arise.

ADMINISTRATION.—Colchicum is never used in substance; the wine of the root is deservedly the most popular preparation. It has been asserted that colchicine hypodermically administered is especially efficacious in rheumatism; the dose is one-fiftieth of a grain (*Berl. Klin. Wochenschr.*, 1877, 197).

The official preparations from the seeds are: the *tincture* (*Tinctura Colchici Seminis*—15 per cent.), dose, half a teaspoonful to one and a half teaspoonfuls; the *wine* (*Vinum Colchici Seminis*—15 per cent., dose, half a teaspoonful to one and a half teaspoonfuls; and the *fluid extract* (*Extractum Colchici Seminis Fluidum*), dose, two to six minims.

The official preparations of the root are: the *wine* (*Vinum Colchici Radicis*—40 per cent.), dose, ten to fifteen drops; as a purgative, half a fluidrachm; the *extract* (*Extractum Colchici Radicis*), dose, one to two grains, and the *fluid extract* (*Extractum Colchici Radicis Fluidum*), dose, two to four minims.

SARSAPARILLA—SARSAPARILLA. U.S.

The root of *Smilax officinalis*, *Smilax medica*, *Smilax papyracea*, and other species of *Smilax*, woody vines inhabiting Mexico and the northern portions of South America. There are in commerce a number of varieties of sarsaparilla, the two most important of which are the *Honduras* and the *Brazilian*. The former of these is almost the only sarsaparilla used in this country. It occurs in bundles two or three feet long, composed of several very long, thin roots, folded upon themselves, the whole being bound round by a number of turns of the root. The Brazilian sarsaparilla also comes in cylindrical bundles, each of which is closely wrapped about by a very flexible stem: it mostly has fewer rootlets than the Honduras variety. The crude sarsaparilla has little or no smell, but its taste, which is at first simply mucilaginous, soon becomes, if the root be chewed, persistently acid. According to Professor Geo. B. Wood, the degree of this acidity is the best measure there is of the activity of any specimen of the drug. There are in sarsaparilla three active glucosides,—*Parillin*, of Palotta, *Saponin*, of Otten, and *Sarsaponin*, of Schulz. To these glucosides, separate or combined, various names have been given by various investigators, such as *amilarin*, *salseparin*, *sarsaparillin*, *parallinic acid*. The three principles belong to the saponin group, and resemble in physiological action saponin from quillain bark. According to Kobert, sarsaponin is about the most active poison to the red blood-disks known, but is less active as a cardiac paralyzant than are most saponins. To it sarsaparilla is believed to chiefly owe any medical value it may possess. Palotta asserts that thirteen grains of parillin will cause vomiting, constriction in the throat, weakness, diaphoresis, and depression of the circulation. On the other hand, Böcker, of Bonn, has exhibited it in doses of a like

amount without producing any symptoms whatever (*Journ. für Pharmakodynamik*, Bd. ii. p. 23). There does not seem to be reason for believing that the saponin principles, in the largest therapeutic dose, of sarsaparilla are in sufficient amount to exert a perceptible influence upon the human system. It has, indeed, been asserted that sarsaparilla acts as a diuretic and diaphoretic; but the only record I have met with of any careful experimentation is that of Böcker (*loc. cit.*). That investigation seems to show conclusively that the drug has no marked influence upon these secretions. If, therefore, sarsaparilla have any value whatever in disease, it must be simply as an alterative,—as a remedy which in some unknown way modifies nutrition.

THERAPEUTICA.—Sarsaparilla has been used, and still is used, to such an enormous extent in medicine that it seems impossible to believe that it is destitute of therapeutic virtue. It is not in accordance with the plan of the present work to enter into an elaborate discussion of the recorded clinical experience with it: suffice it to say that, although the evidence is contradictory, on the whole there is a decided preponderance in favor of the value of the drug in *chronic syphilis* and in *chronic scrofulous diseases*. I have used it largely, but always in combination with more powerful alteratives, so that it is impossible to decide how much of the good achieved has been due to its influence. There are two distinct methods or objects of the use of sarsaparilla in syphilis: one as an adjuvant to mercury in the secondary stage; the other as an adjuvant to the iodide of potassium, or as a sole reliance, in the advanced tertiary cases, especially where the constitution is very much broken down by the disease. It is stated that, in the latter condition, very often during its use the appetite will gradually increase, the spirits rise, the secretions become more and more normal, and the strength grow day by day.

ADMINISTRATION.—Sarsaparilla is never given in substance, but in one of the following preparations:

Decoctum Sarsaparillæ Compositum, U.S.—*Compound Decoction of Sarsaparilla*.—This is made from sarsaparilla, sassafras, guaiacum wood, liquorice root, and mezereum, and is an imitation of the famous "*Lisbon Diet-Drink*." Dose, three or four fluidounces three or four times a day.

Syrupus Sarsaparillæ Compositus, U.S.—*Compound Syrup of Sarsaparilla*.—This contains sarsaparilla, liquorice root, senna, oil of sassafras, oil of anise, and oil of gaultheria, and is a very popular preparation, on account of its pleasant taste: it affords the only vehicle I know of capable of disguising the taste of the iodide of potassium. The dose of it is one to two tablespoonfuls three or four times a day.

Extractum Sarsaparillæ Fluidum, U.S.—*Fluid Extract of Sarsaparilla*.—Dose, half a teaspoonful three times a day.

Extractum Sarsaparillæ Fluidum Compositum, U.S.—*Compound Fluid Extract of Sarsaparilla*.—This contains sarsaparilla, liquorice root, sassafras, and mezereum. The dose is a teaspoonful.

GUAIACI LIGNUM—GUAIAAC WOOD. U.S.
GUAIACI RESINA—GUAIAAC RESIN. U.S.

The heart-wood of *Guaiacum officinale* and of *Guaiacum sanctum*, and the resin of *Guaiacum officinale*, a large tree growing in the West Indies. Guaiac wood, or *lignum-vitæ*, is imported in billets, but very generally is kept in the shops in the form of raspings or shavings. It is a very dense wood, having a dark-olive or brownish-green color. It is inodorous, but becomes somewhat fragrant when rubbed or heated. Besides the resin, it contains an extract which is believed to have medicinal properties.

Guaiac resin is obtained to a slight extent by spontaneous exudation from the living trees; much more largely by boring a hole into the centre of one end of a billet, placing the other end in the fire, and catching the melted resin as it runs out; and still more frequently by boiling the chipped wood in salt and water and skimming off the resin as it rises to the surface. Guaiac occurs in irregular lumps or masses, of a dark reddish-brown greenish color externally, offering a conchoidal fracture with somewhat translucent edges. The odor is feeble, peculiar, agreeable, increased by heat. The taste is at first very slight, but, as the resin melts in the mouth, it becomes very acrid and persistent. It is an exceedingly complex body, containing three acids, the *guaiaconic acid* of Hadelich, the *guaiac acid* of Righini, and the *guaiacresinic acid* of Hlasiwetz, besides *guaiac yellow*, a peculiar resin, and other substances. Landerer asserts that he has found in it a peculiar crystallizable substance, which he calls *guaiacin* (Husemann, *Die Pflanzenstoffe*, p. 1106.)

When a lump of guaiac is freshly broken, it offers a dark, blackish surface, which on scraping or bruising becomes yellowish; on exposure, the well-known greenish tint is acquired, owing to a spontaneous oxidation. The ease with which the resin undergoes oxidation is its most distinctive characteristic. As already stated, the change occurs on simple exposure to the light. According to Wollaston, it is most rapid and perfect in the focus of the violet rays of the spectrum, while in the focus of the red rays the original color is regained. Oxidizing or ozonizing agents, such as nitric acid, chromic acid, iodine, bromine, and chlorine, produce this oxidation very rapidly and very thoroughly, the resin acquiring an intense blue color.

PHYSIOLOGICAL ACTION.—Guaiac is believed by some to act as a diaphoretic, and to do good by increasing the elimination of the skin; but, as I have not been able to obtain either from medical literature or from the exhibition of the medicine any distinctive proof of its having such action to any marked extent, I have preferred to consider the drug as an alterative. When taken internally, very little sensible effect results, unless the dose be so large as to irritate the stomach.

THERAPEUTICS.—Guaiac has been very largely employed in *chronic*

syphilis, in connection with sarsaparilla, and is an ingredient of its most favorite preparations. It has also had a good deal of repute in subacute and chronic rheumatism. Dr. William Murrell (*Med. Press and Circular*, November, 1890) states that in dose of ten to thirty grains the resin given in electuary is very useful as an antirheumatic laxative in various diathetic affections, such as *sciatica*, *tonsillitis*, *chronic rheumatism*, etc. The dose of the simple (*Tinctura Guaiaci*—20 per cent., U.S.) or of the ammoniated (*Tinctura Guaiaci Ammoniata*—20 per cent., U.S.) tincture is from one to two teaspoonfuls, administered, preferably in milk, three or four times a day.

MEZEREUM, U.S.—*Mezereon* is the bark of *Daphne mezereum* and of other species of *Daphne*, native shrubs of Europe. It is a thin, grayish, tough, flexible bark, occurring in long strips folded upon themselves, nearly odorless, but having a very acrid taste. It contains a neutral, crystallizable, bitter glucoside, *Daphnin*, besides a volatile acrid principle. *Mezereon* is intensely irritant, and its ointment (*Unguentum Mezerei*) is used as a stimulant dressing to very indolent ulcers and to keep blisters sore or maintain issues. Internally, in small doses it is believed to be an alterative, but is never used except in combination with sarsaparilla. In overdoses it is an active poison, producing severe vomiting, purging, and gastro-intestinal inflammation. Sometimes the symptoms of the poisoning are simply those of collapse, with unconsciousness and other nervous disturbances, such as are seen in children from intense gastro-intestinal irritation (case, *Brit. Med. Journ.*, 1882, vol. ii. p. 521).

JAMBUL.—The bark of the *Eugenia jambolana*, an East Indian tree, has long been used in India as a stomachic astringent in *diarrhœa* and as a specific in true *diabetes*. Its active principle has not been determined, but appears to be present in the bark, in the seeds, and also in the rind of the fruit (see *Therap. Monatsch.*, 1893); neither have we detailed knowledge as to the physiological action of the remedy. Mr. Thos. Christy (*P. J. Tr.*, 1888) found that when sufficient diastatic matter was mixed with fifty grains of starch to convert forty-five per cent. of the latter in fifty minutes into sugar, the addition of twenty-five grains of powdered jambul seeds reduced the conversion of the starch eighty-eight per cent. In Professor Binz's experiments (*Verhandl. der Kongr. für Innere Med.*, Wiesbaden, 1886), in dogs rendered diabetic by phlorizin, according to the method of Von Mehring, the exhibition of jambul reduced the excretion of sugar from fifty to ninety per cent. without producing any evidences of poisoning.

Clinical reports indicate that in some cases of glycosuria jambul exerts a powerful influence for good, and I have myself seen the sugar entirely disappear from urine under its influence. On the other hand, I have seen it fail to produce any effect, and it is not possible at present

to give any reason for this difference of action; but as no cases of poisoning or disagreeable results from it have been reported, the drug is worthy of full trial in almost any case of glycosuria. The fluid or solid extract of the bark, fruit, or rind of the fruit may be used. The commencing dose of the fluid extract of the bark may be considered to be ten minims, three times a day, rapidly increased to a half drachm or more if no result follow. Dr. Vix gave about ten drachms a day of the extract made from the rind of the fruit. In some of his cases this dose produced violent diuresis.

TARAXACUM. U.S.—The root of the common dandelion, *Taraxacum officinale*, is believed to have the property of altering the action of the liver; although no effect is to be witnessed from a single dose of the drug, however large, other, at least, than some nausea. Diuretic properties have also been ascribed to taraxacum; but the only evidence brought forward to establish this is the vulgar name which the plant bears both in English and in French. If useful at all, it is in those cases of *dyspepsia* in which there is habitual torpor of the liver, with costiveness. It must be given very freely and continuously for weeks before any good effect is to be looked for. The U.S. Pharmacopœia recognizes a fresh juice extract (*Extractum Taraxaci*) and a fluid extract (*Extractum Taraxaci Fluidum*), either of which may be used in doses of one or two drachms, administered after meals.

ICHTHYOL.

Ichthyol is a substance first prepared by Schroeter by the distillation of a peculiar bituminous sulphurous mineral obtained from the deposits of fossil fish. It occurs in commerce in the form of the ichthyo-sulphate of sodium and ichthyo-sulphate of ammonium. The ammonium ichthyol is a red-brown, clear, thick liquid, of a hot bituminous taste and smell, at a high heat burning without ash, making with water a clear, reddish-brown solution of a weak acid reaction, which, when treated with hydrochloric acid, yields a dark resinous precipitate. Sodium ichthyol is a dark, tar-like substance of an alkaline reaction, perfectly soluble in water. Both these preparations combine with fat and vasoline in all proportions. The ichthyol preparations are very rich in sulphur, containing, it is said, ten per cent. According to Baumann, they yield themselves so readily to oxygen that they are powerful reducing agents.

THERAPEUTICS.—According to Baumann and Schotten, ichthyol has little apparent action on the general system, and when given in doses of five drachms to dogs produces no symptoms save diarrhœa. As a local remedy it has been extravagantly praised by Unna, Kiosner, and a large number of German dermatologists and surgeons, and has also received strong encomiums in America. When applied freely in a paste form to the sound skin it produces slight irritation and burning.

It is asserted to have, when used as a local application, peculiar alterative properties, and also the power of penetrating through the skin so as to be able to act as an alterative anodyne and discutient, in diseases not only of the skin but also of the subjacent tissues. The cases in which value is attributed to it are characterized generally by inflammatory enlargement or inflammatory pain.

In various skin-diseases ichthyol has been used with alleged remarkable results, in chronic *eczema*, chronic *urticaria*, *acne*, *intertrigo*, *lupus*, *keloid*, etc. In *lepra* Unna combines its internal and external use (dose, 15 grains a day). It has also been recommended in the strongest terms for the relief of various ulcerations of the skin and for the prevention of putting in *smallpox*, and also in *erysipelas*. In *lumbago* and other forms of *muscular rheumatism*, in *rheumatic* or *gouty joint-disease*, indeed, in almost every form of subacute or chronic *gout*, according to Schweininger, Lorenz, and others, a few rubbings with pure ichthyol or a fifty-per-cent. ointment will produce an immediate and remarkable effect. It has been largely used in the treatment of *sprains*, *contusions*, *burns*, and *frost-bites*. If one-half that has been said of it be true, it is a remedy of extraordinary power and value. Schmidt has even seen it soften and disperse a *lipoma*, and D. Hayes Agnew commends it very highly in the treatment of recent *lymphatic enlargements*. I have used it in sprains with apparently some relief. When the skin is intact and not irritated, the ichthyol itself or a fifty-per-cent. ointment may be employed. In *erysipelas* Von Nussbaum covers the affected part, after thorough disinfection, with a thick layer of equal parts of ichthyol and vaseline, and this in turn with a thick layer of salicylated cotton. The result is said to be immediate, the disease disappearing in a single day. In various skin-diseases and ulcerations the strength of the application may vary from one to fifty per cent. Lorenz affirms that in acute *coryza* and inflammations of the nose or mouth a mixture of one to ten per cent. of ichthyol and vaseline is very efficacious. Both Unna and Lorenz deny that it has any antiseptic properties.

FAMILY IV.—ANTIPERIODICS.

CINCHONA. U.S.

THE U.S. Pharmacopœia formerly recognized three varieties of Cinchona,—namely, the *Cinchona Flava* or *Yellow Cinchona*, *Cinchona Pallida* or *Pale Cinchona*, and *Cinchona Rubra* or *Red Cinchona*. At present, under the general heading of Cinchona, it recognizes the bark of all species of the genus yielding when assayed by the official process not less than five per cent. of the alkaloids and two and five-tenths per cent. of quinine.

The genus Cinchona contains numerous species, yielding quinine and its congeneric alkaloids, indigenous to the western and northern portions of South America, where they grow upon the slopes of the Andes, at an altitude of from five to ten thousand feet. Formerly the only cinchona known to commerce was collected by the *cascañeros*, or woodmen, and exported in large bundles or bales, usually covered by raw hide (*seroons*). The natural commerce, however, in the quinine barks has almost disappeared under the conjoint influence of excessive production by cultivation and reckless destruction of the original forests. At present the world's market is supplied with the cinchona barks chiefly from plantations in the Himalaya Mountains, in Ceylon, and in Java. For a full account of this most important industry the reader is referred to the very able article by Professor H. H. Rusby in the seventeenth edition of the United States Dispensatory.

CHEMICAL CONSTITUTION.—Besides tannic, kinic, and kinovic acids, and other important substances, the cinchona barks contain quinine and quinidine, cinchonine and cinchonidine. Out of these alkaloids quinicine and cinchonine are readily formed artificially, but, so far as is known, they do not exist in nature. There are therefore two isomeric alkaloidal groups: quinine, quinidine, quinicine; cinchonine, cinchonidine, cinchonine.*

QUININA—QUININE. U.S.

This alkaloid was first distinctly separated from the other ingredients of the bark by Pelletier and Caventou in 1820. When quinine is precipitated by an alkali from a solution of its salt, it usually falls

* Out of the quinine alkaloidal groups have been formed by chemists various isomeric alkaloids. For physiological study of these see *Archiv. Physiol. Norm. et Path.*, v., 1893.

as a hydrate, which may be crystalline. By sufficient heat the hydrate is melted and the water is driven off. On cooling, the alkaloid, now free from water, forms a white, opaque, crystalline mass.

The neutral, official *quinine sulphate* (*Quinina Sulphas*, U.S.) occurs in light silky crystals, soluble in seven hundred and forty parts of cold or in thirty of boiling water, readily soluble in alcohol, very freely so in acidulated solutions, nearly insoluble in ether. The aqueous solution, upon the addition of bromine water, and afterwards of ammonia, assumes a green color. According to Dr. G. Kerner, if the original solution be colorless and clear and in a clean test-tube, one-thirty-thousandth part of the alkaloid can be recognized by this chlorine-ammonia test. When to one hundred parts of the salt, dissolved in nineteen hundred and twenty parts of cold dilute acetic acid (sp. gr. 1.042), are added successively four hundred and eighty parts of alcohol (sp. gr. 0.837) and sixty parts of a saturated alcoholic solution of iodine, crystals of *Herapathite* separate, in the form of right-angled quadrate rhombic leaves, which when seen by transmitted light are olive-green, but in reflected light are bright metallic green, resembling the elytra of Spanish flies. When heated, the sulphate of quinine becomes phosphorescent, emitting a pale-green light at 155° to 160° C., and at a higher temperature melts, with the development of purplish vapors. When the neutral sulphate of quinine is dissolved in water acidulated with sulphuric acid, it is converted into the soluble bisulphate, which may be obtained in orthorhombic prisms by evaporation.

PHYSIOLOGICAL ACTION.—Quinine or its salts in powder or solution are, when applied upon a part denuded of its epidermis, very active irritants. Upon the skin they have little or no influence, but upon the mucous membranes they exert a very perceptible stimulant or irritant action.

A. Eulenburg found that when quinine was brought into contact with a nerve it did not cause contraction in the tributary muscles, but when placed upon the muscles themselves it induced immediate violent action. He therefore concludes that it is not a nerve-irritant, but a musculo-irritant. When it is administered to dogs in sufficient quantity, it produces restlessness, followed by muscular tremblings, which have been compared to those of paralysis agitans, loss of power deepening into more or less complete paralysis, great dyspnoea, and cerebral symptoms, such as anaesthesia, blindness, stupor, or violent delirium, dilated pupils, coma, and convulsions. When the drug is introduced by the stomach, vomiting generally occurs, and at times diarrhoea also.* Death has been shown by Heubach to be produced, at least in the lower animals, by a failure of the respiration.†

* See F. M. Melier, *Mémoires de l'Académie*, t. xii. p. 722, 1843; Wm. O. Baldwin, *Amer. Jour. Med. Sci.*, April, 1847; P. Briquet, *Traité thérap. de Quinquina*, Paris, 1855.

† The present is perhaps as suitable a place as any to notice certain researches upon the relations of alkaloids to protoplasm. The relation between medicinal substances and the

The first symptoms of cinchonism, as produced by small therapeutic doses (ten grains) in man, are usually ringing in the ears, slight fulness in the head, and perhaps some deafness. With the use of larger doses these symptoms are intensified: the deafness is very marked, disturbed vision* may exist, and the flushed face, with the sense of distention in the head, may point towards a cerebral congestion, which is in some cases relieved by spontaneous epistaxis. In decided cinchonism, giddiness and staggering in walking are very common. After toxic doses, severe headache, delirium, stupor, complete deafness and blindness, dilated pupils, embarrassment of respiration, great weakness, convulsions, paralysis, and finally collapse, may result, either comatose or delirious. Quinine deafness usually passes off rapidly, but may be permanent. A. Erlenmeyer reports a case of alleged quinine-poisoning, in which the chief symptom was a strychnic-like condition of all the reflexes (*Centralb. Nervenheilk.*, June, 1890). Amaurosis, with a peculiar retinal ischæmia, has been noted (*Archives of Ophthalmology*, x.; for blindness lasting twenty-one days, see *Brit. Med. Journ.*, 1886, i. 823).

The minimum fatal dose of quinine is not known, but it must be large, and probably varies very much. Dr. Clapton details (*Medical Times and Gazette*, April, 1864) a case in which a soldier took at one dose an ounce of the sulphate, stirred up in some water, without the induction of any more serious symptom than a mild stupor; a similar case is mentioned by Dr. Lente, on the authority of Dr. Woodhull; and a third is recorded by Taussig (*Stillé's Therapeutics*, vol. i. p. 507). Dr. R. G. Wharton records (*Amer. Journ. Med. Sci.*, April, 1844) a case in which during thirty-six hours a half-ounce was taken without vomiting and without ill effect. I cannot help suspecting that in all of these cases much of the drug passed through the intestines without absorption. In the famous case of Bazire, five ounces taken in the course of ten days caused death. Fatal instances of poisoning by quinine are very rare in literature, but Husemann (*Therap. Monat.*, Jan. 1888) has made a collection of cases in which death has been attributed to the alkaloid,—not always, in my opinion, with correctness.

A close physiological study of quinine can best be made by investigating its effects upon the different systems of organs *seriatim*; and this shall now be done.

Cerebrum.—According to the experiments of Briquet, a solution of sulphate of quinine injected into the carotid will in some cases produce

tissues upon which they act is certainly a very close one, and very probably is chemical in its nature. Dr. Rosbach (*Pharm. Untersuch.*, Bd. i., Hft. iii.) found that various alkaloids sensibly modify the properties of albumen, and believes that they form a chemical compound with it. Under the influence of the poison the albumen coagulates at a much lower temperature, and is deprived of its affinity for osone. The alkaloids also precipitate the albumen from its osonized solution.

* I have seen complete temporary amaurosis produced in a lady by twelve grains of quinine.

meningitis. In doing this, it is evident, the salt acts rather as an irritant to the membranes of the brain than as a nervous stimulant: indeed, experimental evidence proving that quinine is a cerebral stimulant seems to me to be wanting. The chief proof that the alkaloid does act as a stimulant lies in the fact that persons who have been taking it regularly for some time will occasionally, upon the sudden withdrawal of their daily dose, manifestly be less active without than with it. Briquet may be right in his belief that in small doses it acts as a nervous stimulant, but the proof of his correctness at present is clinical rather than experimental. When given in toxic doses to the lower animals, probably all of the cinchona alkaloids produce epileptiform attacks. Dr. J. Jakoubowich (*Revue des Sciences Méd.*, 1873) has noticed such effect with quinine in dogs, and it has been produced with cinchonidine in various animals. Chirone and Curci found that in the pigeon this action of cinchonidine is prevented by ablation of the cerebral hemispheres, but Professor Albertoni objects with much force that these observers gave the pigeon the alkaloid too soon after the ablation, while it was still profoundly affected by the shock and hemorrhage of the operation (*Arch. f. Exper. Path. u. Therap.*, xv. 278). Professor Albertoni found that, if the pigeon was allowed to recover, the cinchonidine was capable of causing convulsions; also that in dogs with the motor zone of the cerebral cortex destroyed, the alkaloid caused epileptiform attacks, and that therapeutic doses do not increase the excitability of the cerebral cortex in the dog. The subject is one of great interest in connection with the circumstance, noted for quinine by Brown-Séquard and confirmed by Albertoni as regards cinchonidine, that in epileptics the attacks are rendered decidedly more frequent by the cinchona alkaloids. The present evidence indicates that this increase is not due to an influence upon the cerebral cortex, but can hardly be considered sufficient to be conclusive. In very large doses quinine without doubt abolishes the functions of the cerebrum. Louis Dupuis (*L'Action physiol. de Quinine*, Paris, 1877) found that reflex action was normal in poisoned dogs and rabbits, although there was complete loss of sensibility, and he naturally concludes that the latter was of cerebral origin.

Special Sense.—The disorders of special sense produced by quinine seem to be the result of a direct action upon the peripheral sense organs. Dr. Kirchner (*Sitzungsberichte Phys.-Med. Gesells. Würzburg*, 1881, 161) found, in rabbits, cats, and guinea-pigs which had been poisoned with quinine or with salicylic acid, very great congestion of the internal ear and of the labyrinth, with bloody exudation, and with, in some cases, the ear-drum swollen into a bladder-like body by serous exudation. These observations of Kirchner are very interesting, as throwing light upon the cause of the tinnitus aurium and deafness of cinchonism; they are in close accord with the statements of Dr. Roosa (*Amer. Journ. Med. Sci.*, 1874), that sufficient doses of the alkaloid cause

congestion of the blood-vessels of the middle ear, and also with an observation of my own in a person who suffered with chronic inflammation of the middle ear of one side, and in whom a dose of quinine not too large would produce tinnitus aurium of that side, without affecting the sound ear.

Medical literature contains the records of nearly seventy cases of more or less complete amblyopia produced with quinine. (See Kaspar Pischl, *Medical News*, vol. lxiii., 1893.) Sometimes the blindness develops abruptly; more usually it comes on gradually. The length of time which it lasts varies: it may subside with the going off of the specific action of the drug, but not rarely it persists for days, and has lasted as long as three months. The color sense is probably first affected; certainly it usually does not recover itself until after the return of central vision. When the blindness is not complete there is usually pronounced contraction of the field. The pupils are said to be dilated and unresponsive to light.* The ophthalmoscopic examination commonly, but not always, has revealed pallor of the optic disks, with excessive lessening in the size of the retinal vessels; indeed, in some cases there has been complete obliteration of the vessels of the optic nerve. Graefe has, however, noted quinine-blindness with normal ophthalmic appearances, whilst Dickinson affirms that he has seen the optic disks swollen and having the appearance of an ordinary choked disk. The subject has been experimentally studied by Dr. De Schweinitz upon dogs. (See *Trans. Amer. Ophthal. Soc.*, 1891-93.) In these animals the ophthalmological appearances were similar to those which have been noted in man, whilst upon microscopical examination evidences of endo-vasculitis with, in some cases, thrombosis were discovered. Dr. De Schweinitz also found that the prolongation of the quinine-blindness was capable of producing a true atrophy of the optic nerve. It is probable that the primary lesion in these cases is inflammation of the vessels. As the result of an idiosyncrasy, I have seen complete temporary amaurosis produced in a lady by twelve grains of quinine. Usually, however, much larger doses are required.

Spinal Nerves and Centres.—Schlockow was the first to notice a stage of increased reflex activity produced in the frog by quinine: its existence was subsequently denied by A. Eulenburg (*Reichert's Archiv*, 1865), but has been reaffirmed by H. Heubach (*Centralbl. f. Med. Wissensch.*, 1874, 674) and by my pupil, David Cerna, who agree in finding that it occurs only after very minute doses. In his investigations made in the laboratory of the University of Pennsylvania, Dr. Cerna found that this stage of excitement is probably caused by a stimulant influence upon the peripheral sensory nerves, as it did not occur when the ab-

* According to Dr. Rogers (*Journ. Amer. Med. Assoc.*, 1899), one or two hours after the ingestion of twenty grains of cinchonine sulphate there can usually be observed paroxysms of accommodation, which may increase until it becomes almost complete. It seems hardly possible that this phenomenon, if an habitual one, could have been overlooked by other observers.

dominal aorta was tied previous to the exhibition of the alkaloid (*Phila. Med. Times*, x. 493). Two facts, first pointed out by Dr. T. A. Chaperon (*Pflüger's Archiv*, 1869, 295), have been so abundantly substantiated that we must accept them as established. They are—in *small* doses quinine causes in the frog a lessening of the reflex activity, which is removed by section of the medulla, but in *large* doses it produces a permanent palsy of reflex activity. The first of these actions has usually been considered to show that the alkaloid stimulates Setchenow's centre in the base of the brain; but Dr. Sedgwick (*Journ. of Physiology*, iii. 22) believes that the inhibition is such as occurs when a sensitive nerve is galvanized, and is the result of a stimulation of the peripheral afferent cardiac pneumogastric nerve-endings. He bases his theory chiefly on the fact which he has discovered, that atropine prevents the primary inhibition of reflexes by quinine. This is, however, readily explainable without the adoption of the theory of Sedgwick, and, as the results which he obtained after division of the pneumogastries are scarcely in accord with his theory, it is still most probable that quinine is a stimulant of Setchenow's centre. The cause of the permanent influence upon reflex activity has not yet been accurately determined. Chaperon and Wild found that the motor-nerve trunks are unaffected, but this does not prove that the spinal centres are paralyzed, especially as Wild's experiments seem to show that the nerve-endings in the muscles are attacked. (See below.) A. Eulenburg (*Reichert's Archiv*, 1865) asserts that voluntary movements persist after reflex actions, and that the quininized frog will turn into its normal position when laid upon its back, although ordinary reflex actions are completely abolished. This, if correct, certainly shows that it is either the sensory nerves or the receptive centres of the cord whose paralysis by quinine puts an end to ordinary reflex movements. So that, accepting the various results reached by experimenters, it is probable that in frogs quinine first excites and then paralyzes the peripheral sensitive nervous system. How far this applies to man is uncertain. According to the experiments of H. Kobert (*Archiv f. Exper. Path. u. Therap.*, xv. 49), very large doses of cinchonine, and probably therefore of quinine, lessen the excitability of the muscles. This is confirmed by the experiments of R. B. Wild (*Brit. Med. Journ.*, vol. ii., 1887), who finds that solution of quinine one to one thousand brought in contact with the isolated muscle of the frog diminishes irritability of the muscle and alters to some extent its relations with stimulation. The peripheral nerve-endings appear to be more sensitive than is the muscle, for when a solution of one to four thousand was employed galvanization of the nerve failed to elicit a response, although the muscle contracted when the current was applied to it directly.

Abdominal Organs.—Upon the stomach and intestines quinine acts very much as a simple bitter. In moderate doses it stimulates digestion and increases the appetite; in large doses it not unfrequently causes

nausea and vomiting. When there is any morbid irritability of the mucous membrane of the stomach or bowels, its irritant action is often very marked; and its continued use in large doses has been known to cause gastritis.

Many years since, M. Piorry asserted that a large dose of quinine would produce a distinct immediate lessening of the size of the spleen in cases of intermittent; but the testimony of very numerous observers to the contrary is so concurrent as to render the truth of his observation highly improbable. Several observers* have stated that the exposed spleen of an animal can be seen to contract when sulphate of quinine is injected into the stomach, veins, or cellular tissue; but other investigators† have failed in their attempts to produce this asserted contraction. The experiment necessitates such abnormal exposure of the organ that only a very pronounced and very constant diminution could establish the assertion that quinine produces contraction of the spleen, and our present knowledge indicates that the alkaloid has no immediate decided influence on the size of the organ.

Organs of Circulation, and Blood.—Briquet, who first studied closely the action of quinine upon the circulation, found that in large doses it lowers the arterial pressure in the lower animals. The experiments have been confirmed by various observers, notably by Schlockow (*De Chini Sulfavici*, etc., Bratisl., 1860), A. Eulenburg (*Reichert's Archiv*, 1865), and Cerna (*loc. cit.*, 184). It has been abundantly proved that the alkaloid thrown into the jugular vein, introduced into the coronary artery, or in any way brought in contact with the heart, lessens the force and frequency of the pulsations, and finally produces diastolic arrest; also that this result is not influenced by separation of the mammalian heart from the nerve-centres, and occurs in the cut-out frog's heart. In man, very large doses of quinine (thirty to sixty grains) lower the force and frequency of the pulse; a pulse-rate of forty has been noted, and in reported cases of quinine-poisoning the pulse has been imperceptible at the wrist. Under the latter circumstances the pulse-rate may be increased, but the cardiac force is reduced to a minimum. The evidence is conclusive that both in man and in the lower animals quinine in sufficient amount is a powerful depressant to the heart-muscle or ganglia.‡

Schroff (*Med. Jahrbücher*, 1875) found that in the quinized animal neither galvanization of a sensitive nerve nor asphyxia was able to

* M. Piorry, *Archives Océrales de Médecine*, 1847; M. Pagès, *Gazette Médicale*, 1848; also Dr. Küchenmeister, *Archiv für Physiol. Heilkunde*, Bd. x.; M. Mosler, *Pathologie der Leukæmie*, Berlin, 1872, p. 451; Jerusalemky (*Centralblatt f. Med. Wiss.*, 1876, p. 476). The latter observer believes the contraction to be caused chiefly by an action on the peripheral splenic nerves and muscles.

† Magendie (*Gas. Méd.*, 1847), and especially L. T. Bochefontaine, *Recherches expérimentelles à la Contractilité de la Rate*, Paris, 1873.

‡ Pantellejeff (*Centralbl. f. Med. Wissensch.*, 1880, xviii. 529) states that atropine will cause the heart arrested by quinine to recommence its action.

produce vascular contraction and rise of blood-pressure, and Jerusalemsky (*Centralbl. f. Med. Wissensch.*, 1876, p. 476) asserts that in frogs dilatation of the vessels could be seen.* Further, Professor Kobert, experimenting with the excised organs of the warm-blooded animals, and Mr. Wild, experimenting with the tortoise, prepared according to the method of Dr. Stevens and Donaldson, have found that very weak solutions of quinine sulphate (one part to five thousand) cause enormous dilatation of the vessels, with consequent increased rapidity of passage through them of liquid under pressure. It is probable, therefore, that the fall of the arterial pressure in poisoning by quinine is in part the result of an action upon the vessels.†

Both Schreff and Jerusalemsky noticed that the fall of arterial pressure produced by quinine is preceded by a rise of the pressure, accompanied with an increase of the cardiac action. This observation has been confirmed by G. Sée and Bochefontaine (*Compt.-Rend. Acad. Sci.*, t. xvi. p. 267); but no observer seems to have shown that the rise of pressure is more than a temporary phenomenon. Sée and Bochefontaine affirm that the increased cardiac action continues some time after the pressure begins to fall. The primary rise of pressure may be the result of a stimulant action upon the vaso-motor centres, as Jerusalemsky found that it was not produced after division of the cord. Jerusalemsky attributes the increase in the pulse-rate to paralysis of the inhibitory apparatus, a view which is supported by the assertion of Cerna that previous section of the pneumogastric prevents the quickening of the pulse-rate.

I have never been able to perceive any depressant action upon the circulation in man after ordinary therapeutic doses (three to five grains) of quinine, and I believe that in tonic doses quinine produces no perceptible sedation of the circulation, but that the largest antiperiodic doses have a distinct influence.‡

According to Bonorn and Arvedi, to Magendie, to Monneret, to Me-lier, and to Baldwin, in animals killed with quinine the blood is found to be dark, defibrinated, fluid, and incapable of forming a clot. Briquet, however, denies that this alteration of the blood is constant, or even common, in quinine-poisoning, as he found it in only four out of twenty-

* M. Chirone believes that by quinine the heart is arrested in active dilatation. The theory is very improbable. See *Rivista Clinica di Bologna*, abstracted in *Journ. de Physiol. Norm. et Patholog.*, 1876, p. 844.

Heubach, in a series of experiments on the influence of galvanization of a sensitive nerve upon the circulation after the exhibition of quinine, failed to detect any paralyzing action of the drug, although in some of his experiments the reflex activity was paralyzed.

† When, in Wild's experiments, the action of quinine was maintained for a length of time, the dilatation was finally followed by contraction, which contraction was in all probability the outcome of a post-mortem rigidity.

‡ Some studies have been made upon the action of the drug on the capillaries of the brain, but the evidence is contradictory and insufficient. Consult *Psychological and Medical-Legal Journal*, 1875, p. 33; also *Archives of Medicine*, I. 33.

three dogs so sacrificed; and he believes that it is merely an accident dependent upon the method of death,—a conclusion which has been confirmed by Dr. H. A. Hare. In a series of analyses Briquet found that the continued use of quinine augments the proportion of fibrin, but lowers that of the red corpuscles.

In 1867* Professor Binz announced the fact that quinine added to human blood in the proportion of one part to four thousand immediately checks and in a short time arrests the amœboid movements of the white blood-cells. Confirmation of this has been furnished by Scharrenbroich (*Inaug. Dissert.*, Bonn, 1867), by Kerner (quoted in *Practitioner*, vol. vii. p. 321), by Geltowsky (*Practitioner*, vol. vii.), and by Jerusalimsky (*Centralbl. f. Med. Wiss.*, 1876, p. 476). The minimum effective strength of the solution has been found to vary in different species of animals, and even in different individuals of the same species.

It is a matter of great interest to determine whether quinine acts in the living organism as on the stage of the microscope; and, to settle this point, Professor Binz (*Virchow's Archiv*, 1869, Bd. xlv. p. 138) has experimented according to the method of Cohnheim. He found that when the mesentery of curarized frogs to which quinine had been given was exposed upon the stage of the microscope, no accumulation of white blood-cells in the small vessels, or passage of them out into the tissues, occurred upon irritation; or, if after a time these phenomena commenced, they were at once checked by a small hypodermic injection of the alkaloid. When the inflammatory process had already commenced in a "Cohnheim frog," an injection of quinine would cause the out-wandering of the corpuscles to cease, and would bring about a gradual clearing of the white cells from the choked-up vessels. Professor Binz further took two young cats, and, after poisoning one of them with quinia, examined their blood. In the blood of the unpoisoned animal the white cells were far more abundant than in that of the poisoned cat. From these facts Professor Binz deduces the conclusion that quinine acts destructively in the system upon the white blood-corpuscles, in the same way as when they are out of the body. Dr. Geo. R. Cutter (*Psycholog. Medico-Legal Journ.*, Feb. 1875) and Dr. H. A. Hare (*Phila. Med. Times*, xv. 43) have experimentally confirmed the effect of quinine in preventing the extrusion of white blood-cells from the frog's mesentery, and A. Martin† (*Inaug. Dissert.*, Giessen, 1868) has also found that the action of the drug is apparent in the centre of parenchymatous organs, such as the liver.

On the other hand, Schwalbe‡ could detect no difference in the blood of a cat before and after poisoning by quinine; and the experi-

‡ Quoted by Kerner, *Müller's Archiv*, Bd. i. p. 203.

ments of Geltowsky (*loc. cit.*) upon frogs and guinea-pigs have yielded similar results: in all cases after fatal poisoning by the alkaloid the movements of the corpuscles were found to be very active.

The correctness of the original observation of Professor Binz upon the out-wandering of the white blood-corpuscles in the Cohnheim frog must be considered as established, but it is not proved that the failure of the blood-corpuscles to escape from the irritated vessels is due to the arrest of their amoeboid movements by the quinine. In a series of experiments Dr. H. A. Hare (*loc. cit.*) found that the vessels in the cinchonized frog were much more contracted and had their walls much thicker than in a corresponding frog without quinine. This contraction of the vessels is thought by Dr. Hare to be the result of a direct action exerted by the drug upon the muscular coat of the arterioles. It is certain that the alkaloid reduces very markedly the force of the heart. It is, therefore, possible that the quinine prevents the out-wandering by lessening the force which is driving the corpuscles and at the same time increasing the resistance of the capillary walls. It must be considered still doubtful how far quinine affects the white blood-corpuscles in the circulation even when it is administered in poisonous doses. When therapeutic doses are employed, the doubt as to its powers is of course still stronger.

It would seem that quinine acts also upon other portions of the blood than the white corpuscles. Manassein (*Ueber die Dimensionen der rothen Bluthorperchen unter verschiedenen Verhältnissen*, Berlin, 1872) has found that in fever occurring in the lower animals the red corpuscles are diminished in size. If in this condition a decided dose of an antipyretic, such as quinine or alcohol, be given, and the temperature falls, the globules resume their normal size. That the change is due to the fall of the temperature rather than to a direct action of the drug is, I think, demonstrated by the fact of its occurrence whenever the fever-heat is lowered by the application of external cold. The experiments of Manassein, therefore, do not prove that quinine exerts any direct action on the red corpuscles. The investigations of Binz (*Arch. f. Exper. Path. u. Pharm.*, Bd. i., Heft i., 1873), however, appear to show that the alkaloid lessens the ozonizing power of the blood; for he found that in young cats to which he had given a very large but not fatal dose of quinine the freshly-drawn blood affected the tincture of guaiac much less than it normally should.

When blood is drawn from the body and allowed to stand, acid is developed in it. Zunst (*Inaug. Dissert.*, Bonn, 1868), who has studied this subject most closely, divides the investigation into study of the production of acid in the time from the escape of the blood from the vein to its coagulation, and study of the slow changes which increase its acidity when coagulated until putrefaction has fairly set in. Professor Binz believes that this development of acid is due to oxidation, and by an elaborate series of experiments has determined that quinine

(also sulphate of bebeerine and picrate of sodium in almost as great degree) inhibits these changes very greatly in both their varieties. These experiments are in accord with the previous ones of A. Schulte (*Centralbl. f. Med. Wissensch.*, Nov. 1871): the facts may, therefore, be considered proved.

If ozonized oil of turpentine be dropped into an alcoholic solution of guaiac resin, no alteration of color occurs; but if a drop of blood be added, the blue appears at once: i.e., the blood acts as a carrier of ozone from the turpentine to the resin. Professor Binz has found that quinine, even in so small an amount as one part in twenty thousand, has a perceptible influence in preventing this. Similarly, when into a dilute watery solution of the sulphate of indigo carbonate of sodium is thrown until the reaction is decidedly alkaline, and a little blood, and subsequently ten drops of ozonized turpentine, are added, a green color begins at once to develop, and in a little while passes into the clear yellow of isatin. In this case also the blood acts as a carrier of ozone; and Binz and his pupil Ransoné (*Inaug. Dissert.*, Bonn, 1871) have found that quinine also inhibits this action, one part of it added to a thousand of the mixture delaying the change of color for an hour. In these experiments Binz used a large number of different salts of quinine, and found that they acted identically. That the action of the alkaloid was on the blood, not on the indigo and guaiac solutions, was shown by the fact that when similar solutions without the blood were shaken in the air and absorbed ozone, the characteristic colorations of its action were produced just as readily when quinine was absent as when it was present. Binz also proved that the red corpuscles were the portions of the blood affected. On adding crystallized hæmoglobin from horses' blood to the guaiac solution he found that it acted as an ozone-bearer between the turpentine and the guaiac, and further demonstrated that quinine had the power of preventing this action.

As it is established that quinine exerts some antipyretic action (see p. 637) in ordinary fever, it is an exceedingly plausible theory that the lowering of temperature is due to a checking of the ozonizing power of the blood. To attribute, however, the general medical virtues of quinine to an action on the white corpuscles seems to me unreasonable; for from the experiments of Professor Binz himself upon the lower organisms it would appear that quinine acts upon all animal germinal matter; and it is probable that the protoplasm of the nervous system, being more specialized than that of the white corpuscles, would be more susceptible to the influence of the alkaloid. Professor Binz states that both conine and camphor act more forcibly upon the white corpuscles out of the body than does quinine, and Drs. T. Lander Brunton and Theo. Cash have found that morphine, veratrine, and codeine check the ozonizing power of the blood, while digitaline, picrotoxine, and caffeine increase it. Each of these principles has its own peculiar physiological action, differing from that of quinine and

the other alkaloids (*St. Bartholomew's Hosp. Rep.*, xviii. 269). It seems, therefore, to me absurd to attribute such diverse physiological actions to the one common property of the group, and I think that we must consider the antozonizing power of quinine as simply one of its functions, and not as the basis of all its relations with the human organism.

Antiseptic Action.—As long ago as 1765, Dr. Pringle (*Observations on Diseases of the Army*, London, 1765) called attention to the fact that cinchona bark, in decoction or powder, has the power of preventing for a time putrefaction in flesh; and more recently the subject has been studied by Mayer, by Pavis, by Hallier (*Das Cholera-Contagium*, Leipzig, 1867), by Herbst, by Polli, and especially by Binz (*Virchow's Archiv*, 1869, Bd. xlv. p. 68; and *Untersuchungen über das Wesen der Chininwirkung*, p. 20), to whose elaborate articles I must refer my readers for details and references. The experiments of these authorities have demonstrated that quinine in the proportion of one part to three hundred will preserve for a long time flesh, meat, milk, butter, urine, albumen, etc., and will check very markedly the alcoholic fermentation in honey or in syrup. Professor Binz has proved that this antiseptic action is due to a poisonous influence exerted by the quinine upon the fungi which are the immediate cause of the changes. According to his experiments, the larger infusoria, such as *Paramecia* and *Colpoda*, are killed by a solution of quinine of the strength of one in eight hundred immediately, of one in one thousand after some minutes, of one in twenty thousand after some hours. Upon the ordinary mould *Penicillium*, upon *Vibrios* and *Bacteria*, as well as upon the higher infusoria, quinine acts with a similar fatality. In the case of the *Vibrios* and *Bacteria* a decidedly stronger solution than the one mentioned is required to quiet movement. Bochefontaine (*Archives de Physiologie*, July, 1873) found that a solution of one per cent. was needed for a vigorous rapid action, and that some active granules could even be found in it after three days. According to Binz, the singularity of the influence of quinine is shown by the fact that a solution of salicin in the proportion of one part to forty does not kill *Paramecia* and *Colpoda*. Indeed, these infusoria were not even affected by this strong solution of salicin, and they endured a solution of morphine of one part to one hundred and twenty for an hour, and a five-per-cent. solution of strychnine for some minutes. Although fungi will appear after a time in ordinary solution of the sulphate of quinine, I think it must be considered well established that this and other salts of the alkaloid are extremely poisonous to the fungi of putrefaction and of other ordinary fermentations.

Uterus.—In 1871, Dr. Monteverdi announced (*Annales et Bulletin de la Société de Médecine de Gand*, May, 1871) that quinine is a uterine stimulant, causing at times in the gravid womb contractions sufficiently violent to induce abortion, and, when given during labor, intensifying greatly the uterine pains, and after labor causing rapid expulsion of

the placenta and arresting uterine hemorrhage; affirming, further, that in amenorrhœa or in menorrhagia from uterine inertia its action is no less marked. Although this has been received as new the world over, so long ago as 1855 Dr. John S. Wilson (*Southern Medical and Surgical Journal*, p. 341, 1855) called attention to the uterine action of quinine, and in 1860 reasserted his belief (*Southern Journal of Medicine*, Sept. 1860), which in the mean while had been confirmed by Dr. J. H. Rich in the *Charleston Medical Journal and Review*; and in 1858 Dr. Jos. J. West (*Savannah Journal of Medicine*, i. 19) wrote, "Many regard the use of quinine as dangerous and even criminal in any diseases in pregnant women. The belief of these persons is that this substance exercises a direct influence upon the uterus, causing powerful contractions and expulsion of the fœtus. And to support this notion they are ready to bring forward innumerable instances of abortion after its use,—of cases of sudden suppression relieved by a prompt use of the same remedy." He then goes on to say that these abortions, etc., were due to the intermittent fever and not to the drug. Surely this is enough to show that the oxytocic action of quinine was believed in many years ago by numbers of our Southern practitioners. The question now is whether the drug has any such action. It is evident that the answer to this should be made out in three different ways. First, Is there any evidence of quinine producing abortion in healthy women or in females of other animals? Second, How strong is the evidence of its producing abortion in women suffering from ague? Third, What is the evidence in regard to the action of quinine during labor?

In regard to the first of these sub-questions, the only affirmative evidence I have met with is in the experiments of M. Rancillia (*L'Union Médicale*, 1873), who saw abortion in two bitches follow the administration of from six to nine grains of quinine: as the pups in one case were already dead before the administration of the drug, it would seem that this investigation was not on such a scale as to be at all conclusive. Moreover, I have given quinine to two pregnant cats, in one case in sufficient quantity to cause death, without disturbing the products of conception. Furthermore I have met with no evidence that quinine is capable of inducing abortion in healthy pregnant women. Dr. Sayre's case (*American Practitioner*, 1871, p. 260) is certainly no proof whatever that quinine will originate labor, as labor had commenced under the influence of the hot and cold douche and other measures employed before the quinine was given. Professor Chiara, of Milan, has furnished (*L'Union Médicale*, Nov. 20, 1873) very strong evidence that quinine is incapable of originating uterine contractions in healthy pregnant women. In his public service, two doses of a gramme (15.34 grains) each were given without effect daily for two successive days to eight women all in the eighth month of pregnancy. It being necessary to cause abortion, one gramme was given daily to one woman for seven days, to another for three days, without in either instance any effect,

so that the labor had to be brought on in the usual manner. On the whole, I believe that the first question must at present be answered in the negative.

In answer to the second sub-question, some evidence has already been adduced to show that abortion may be so caused. To it may be added the assertion of Dr. Walraven (*Bost. Med. and Surg. Journ.*, 1873) that he has frequently seen the exhibition of quinine followed by abortion, the record of two cases of such character by Dr. Burt (*Medical and Surgical Reporter*, 1870), and no doubt the affirmations of others which I have not seen. Opposed to this, however, is the overwhelming fact that the great body of the profession have for centuries been giving quinine in one form or other to pregnant women indiscriminately, and if abortion had been produced it must have been noted long ago. Further, direct testimony is not wanting. Malaria often induces abortion, and Dr. Erwin (*St. Louis Medical and Surgical Journal*, March, 1872), Dr. Jas. C. Harris (*American Practitioner*, April, 1872), and Dr. A. Russwurm (*American Practitioner*, 1871, No. 4, p. 127) testify from personal experience that quinine will arrest abortion from such cause. Dr. J. A. Ashford (*National Medical Journal*, Oct. 1871), Dr. Beauchamp (*American Practitioner*, 1870), Dr. Rooker (*Ibid.*), Dr. J. S. May (*Ibid.*), and Dr. A. d'Arcourd (*Medical News and Library*, May, 1873) have given the alkaloid to hundreds of pregnant women in large doses without result. Other testimony might be adduced; but it seems to me incredible, in the face of daily experience, that even the largest therapeutic doses of quinine are abortifacient in malarial fevers or in health.

In regard to the third sub-question,* it seems to me proved that quinine in full doses (ten to twenty grains) is a very powerful stimulant to the uterine contractions during labor. The pains it produces so exactly simulate the natural ones as to indicate that they are not so much caused by a specific action of the drug as by its arousing the general nervous forces of the system. Be this as it may, most of the leading accoucheurs of this city and of New York are accustomed to rely upon quinine in cases of uterine inertia from exhaustion.†

Voluntary Muscles.—C. G. Sauterson, in a series of experiments both upon cold- and warm-blooded animals, has found that quinine acts directly upon the muscle-fibres, increasing the susceptibility and power of the muscle, but, especially in the cold-blooded animal, causing it to

* For details of the evidence the reader is referred to the third edition. Consult also *Practitioner*, xvii., xviii., xix.

† Certain experiments of Wild (*Brit. Med. Journ.*, vol. II., 1887) suggest that the quinine may act directly upon the muscle-fibres of the uterine walls. He found that when the solution of quinine sulphate, one part to a thousand, was brought in contact with the isolated œsophagus of the frog, the œsophagus first shortened, and afterwards lengthened beyond its normal limit, the change probably being, as believed by Wild, due to stimulation first of the weak longitudinal muscular fibres, and later of the more internal stronger circular fibres, as the quinine penetrated the coats. The muscle-fibres of the œsophagus are similar to those of the uterus.

become fatigued more readily than normal (*Arch. f. Exper. Path. und Pharm.*, xxx., 1892).

Kidneys and Elimination.—The manner in which quinine finds entrance into the blood has been especially studied by Dr. Kerner (*loc. cit.*). As the gastric juice is very acid, it is evident that the alkaloid will be rapidly dissolved in the stomach and be put into the conditions most favorable for its absorption: if, however, the salt of quinine escapes from the stomach into the intestines, it will be liable to be precipitated by the alkaline juices, as well as by the bile, whose acids form very insoluble salts with it. The presumption is therefore strong that, when gastric absorption fails to take place, at least a portion of the quinine will pass out with the feces. That this actually does occur has been proved by Kerner and others, who have found the alkaloid in the excrement of persons taking it. As the blood is alkaline, it would appear probable that the quinine salt so soon as entering it would be precipitated. That this does not occur, according to the researches of Kerner, is due to the solvent power of the gases contained in normal blood.

The authority mentioned found that one thousand parts of blood which was defibrinated and deprived of its gases, at a temperature of 36° C. dissolved in an hour only 0.398 part of pure quinine. Water saturated with carbonic acid gas dissolves the sulphate of quinine pretty freely; and Kerner also experimentally determined that when a neutral solution of a salt of quinine is added to a very dilute solution of carbonate of sodium no precipitate occurs. It would appear, then, that the quinine is held in solution in the blood by reason of the loosely-combined carbonic acid gas in that fluid.

It has been proved by the analyses of Landerer (*Repertorium für Pharmacie*, Bd. xxv., 1836), of Dietl (*Wiener Medizinische Wochenschrift*, 1852), of Briquet (*loc. cit.*), of Binz, and of De Renzi (*Bull. Therap.*, t. xci. p. 45), that quinine escapes from the body through the kidneys. According to Briquet, it may generally be found in the urine half an hour after the administration of a large dose. Its removal, according to the researches of Binz, goes on slowly, for it is stated (*loc. cit.*, p. 167) that in six experiments only a little more than two-thirds of the ingested quantity was excreted in the first forty-eight hours. Further, De Renzi, Yvon, and Dietl (*Die Pflanzenstoffe*, 1883, p. 1443) have found it in the urine six or seven days after the ingestion of the last dose. Dr. L. Thau, however, in three experiments, out of the 4.4586 grammes of the alkaloid which were given, recovered from the urine passed during the forty-eight hours 4.3 grammes, so that only 0.1586 gramme remained unaccounted for. A portion of this residue was perhaps lost in the chemical operations; but it is probable that some of the quinine is eliminated through other channels than the kidneys, since Professor Binz has found it in the saliva of a poisoned dog, and Landerer (*Buchner's Repertorium*, 1839 and 1842) states that he has

detected it in the urine, sweat, tears, milk of nursing women, and in the serum of dropsical effusions, while Albertoni and De Renzi find it abundant in the bile when it has been taken by the mouth, but not when it has been given hypodermically. Dr. Thau determined that from a third to somewhat less than half of the ingested quinine escapes from the body in the first six hours, and that in the first twelve hours about three-fourths are excreted.* Welitschkowski found (*St. Petersb. Med. Wochenschr.*, 1876) an elimination of sixty-five per cent. the first day, and twenty-five per cent. the second day. Prior gives the second day as the usual final limit of elimination. I think we may consider that after a few doses the alkaloid is practically eliminated in forty-eight hours, but that when it has been given continuously, or when kidney-disease or great feebleness of circulation exists, the system may contain a notable amount of the quinine for a longer period. The researches of Welitschkowski are in accord with those of Jürgensen and Thau in showing that in cardiac and renal disease and in low fevers elimination proceeds very slowly, more of the alkaloid being thrown off in the second than in the first six hours after its ingestion.

Ranke was, I believe, the first to notice that quinine produces a great decrease in the elimination of uric acid. This was confirmed by H. V. Boase (*Inaug. Diss.*, Dorpat, 1862) and by Dr. G. Kerner (*Pflüger's Archiv*, 1870, iii. 93). The latter observer found that, when about nine grains of quinine were taken in divided doses during the course of the day, the urea was decreased not quite one-eighth, the uric acid to a little less than one-half, the kreatinine was slightly increased, and the nitrogenous material decreased about one-ninth. When a very large dose (thirty-eight grains) was taken in the morning, the urea and the kreatinine were each decreased about one-fourth, as was also the collective nitrogenous material; the phosphoric acid was lessened about one-fifth, and the uric acid about four-fifths. Zuntz (quoted by G. Strassburg, *Archiv für Exper. Path.*, Bd. ii. p. 343) found that twenty-five grains of quinine reduced his elimination of urea nearly forty per cent. A. Schulte also found 1.8 grammes of quinine depress the elimination by the kidneys thirty-nine per cent. (*Inaug. Diss.*, Bonn, 1870); yet in the experiments of Unruh (*Virchow's Archiv*, 1869, xlviii. 227) the action of the alkaloid in depressing urea elimination was not constant,

* Dr. G. Kerner (*Pflüger's Archiv für Physiologie*, 1870) asserts that the quinine as excreted is in an amorphous, uncrystallizable form. He also has discovered in the urine of persons taking quinine a peculiar substance, sometimes amorphous, sometimes in acicular prismatic crystals, free from bitter taste, possessing the quinine inflorescence, which he believes to be a derivative formed in the body from the ingested alkaloid. He has not been able to get this substance in such quantity as to analyse it or further examine it, but has produced a principle (*dihydroxyle quinine*) which he believes to be identical with it by acting on quinine with the permanganate of potassium. An elaborate series of experiments have shown that the dihydroxyle quinine is physiologically inert. This dihydroxyle quinine must be produced in small amount, if at all, as there is abundant evidence that quinine is largely excreted as quinine (see *Pharm. Journ. and Trans.*, ix. 125).

and in the trials of H. Oppenheim (*Pflüger's Archiv*, 1880, xxxiii. 446) the excretion of urea was actually increased. Nevertheless, the experiments, upon the dog, of Rabuteau (*Bull. Thérap.*, lxxv. 475) and of Hermann von Boeck (*Untersuchungen über die Zersetzung des Eiweisses im Thierkörper*, Munich, 1871), bear strong evidence to the fact that quinine does decrease the elimination of urea; and the recent very elaborate studies of Dr. Prior (*Pflüger's Archiv*, Bd. xxxiv. p. 237) warrant us in believing it established that quinine powerfully depresses the elimination of the nitrogenous excretory principles. That such decrease is due to diminished formation, and not to lessened elimination, seems proved by the fact that in Prior's experiments there was no increase of nitrogenous excretion beyond the norm following the omission of the quinine. It seems to be established that quinine has a direct or indirect depressing influence upon the tissue-changes of the human organism.

Contrary to what might have been expected, Strassburg, in an elaborate series of experiments, found that quinine had no decided effect upon the elimination of carbonic acid either in healthy or in fevered rabbits. These observations of Strassburg are opposed by those of Boeck and Bauer (*Zeitschr. für Biolog.*, Bd. x.), who found that in cats large doses of the alkaloid cause in the first stage of their action lessened carbonic acid production, but that when the convulsions appear the carbonic acid is increased as the result of the increased muscular activity. Professor R. H. Chittenden (*Studies from the Laboratory of Yale University*, vol. ii. p. 223) found that fatal doses of quinine given to fasting rabbits had no decided effect upon carbonic acid production until just before death, when both the animal temperature and the excretion of carbonic acid fell distinctly. On the other hand, small doses of quinine seemed to cause a gradual falling off in the carbonic acid elimination. Although the evidence is somewhat contradictory, it appears to show that any action of quinine upon carbonic acid elimination must be very feeble and uncertain.

THERAPEUTICS.—At present our estimate of the value of quinine in disease, and our knowledge of its therapeutic use, rest solely upon clinical observation, although recent researches have enabled us to frame at least a plausible explanation of the method in which it overcomes malarial disease.

On account of its power of arresting or preventing putrefactive fermentation by killing the microscopic entities which produce such changes, Professor Binz has recommended it in the so-called *septic diseases*. The chief evidence which he produces is in some ten experiments made upon dogs and rabbits. In each of these experiments two similar animals were poisoned with putrescent liquids, and to one of the pair quinine was freely administered. In two cases the cinchonized animal recovered, while its fellow perished; in three experiments neither of the animals died; and in the other five trials the cinchonized animal lived from two to twenty-four hours longer than the other.

These experiments are certainly too few and indecisive to prove in any degree Professor Binz's view. To my mind they indicate very strongly that quinine has no such influence over the disease as he claims for it. If living germs in the blood were really the cause of the septic symptoms, and if quinine killed such germs, its action would be as manifest and as unmistakable as it is in intermittent fever. The results of Professor Binz's experiments indicate no such specific action, but rather that the quinine in such cases does good by sustaining the nervous system, or in some other unknown manner. In *pyæmia* in man, quinine has been frequently employed, but exerts no specific action.

It has not, that I know of, been proved that therapeutic doses of quinine lower, to any marked extent, bodily temperature in the healthy man. Dr. G. Kerner and Dr. Jürgensen have each noticed that full doses of quinine appear in a healthy man not to affect sensibly the temperature, but to prevent the rise which normally occurs from exercise. Thus, in Kerner's experiment, certain gymnastic exercises, which when performed in his ordinary state elevated his bodily temperature 2° C., affected the latter to the extent only of 0.2° to 0.35° C. when quinine was freely exhibited.

Even Dr. C. Liebermeister (*Deutsch. Arch. f. Klin. Med.*, 1867, Bd. iii.) acknowledges that numerous experiments have shown him that the alkaloid has no constant action on the bodily heat in health, and details a case in which forty grains administered within seven hours caused no depression of temperature. The same authority claims, however, that by a very large number of experiments he has demonstrated its power of lessening fever-heat. In one hundred and seventy-eight observations in *typhoid fever*, twenty grains of the quinine having been given during the night, the morning temperature was lower than that of the previous evening by, on the average, 1.63° C. On one hundred and seventy-six different occasions a scruple of quinine was given during the day; sixty-nine times the temperature was lower in the evening than in the morning, ten times it was the same as in the morning, and ninety-seven times it was higher than in the morning. A committee appointed by the London Clinical Society (*Transactions*, 1870, vol. iii. p. 201) experimented with the drug on about fifty cases of various diseases. They assert that the antipyretic action of large doses was very decided, appearing within from one to two hours after the exhibition of the drug, and lasting from a few to many hours. In a very recent publication Liebermeister states that he has given some ten thousand doses of quinine as an antipyretic and has almost unbounded confidence in it. He insists that from twenty to forty-five grains must be given *within the hour*, and not repeated oftener than once in twenty-four or forty-eight hours.

Naunyn and Quincke (*Reichert's Archiv*, 1869) found that sometimes quinine prevented the development of fever after the division of the spinal cord in animals, but in other cases failed to do so. Binz

(*London Practitioner*, p. 4, 1870) has achieved similar results: he says that if the conditions of the fever are too favorably constituted the effect of the quinine fails thoroughly. The drift of our present clinical evidence seems to indicate that quinine exerts in febrile disease a decided antipyretic action, which is especially manifested during those stages of disease in which the natural tendency is towards a lowering of temperature. In *typhus* and *typhoid fever*, *scarlatina*, severe *erysipelas*, *rheumatic hyperpyrexia*, etc., after the use of the cold bath (see Part I.) twenty grains of the alkaloid are often efficacious in delaying the return of the excessive fever. If the experiments spoken of above be correct, this reduction of temperature must be due to an action on the tissues and not on the central nervous system. It would seem, however, more probable that quinine acts as an antipyretic by stimulating the inhibitory chemical centre; but decision of this must be reserved for future investigations. As an *antipyretic* the drug may be used whenever there is serious elevation of temperature, except it be in cases of simple inflammation of the brain or its membranes. All antipyretic remedies appear to act more strongly on children than on adults; and accordingly Dr. Rapmund (*Deutsche Klinik*, 1874, p. 51) has found quinine of the utmost service in serious diseases of children with high temperature, especially *lobular pneumonia*. Much of the failure which has hitherto attended its employment undoubtedly has been due to a faulty method of administration.

As a simple tonic, quinine is largely used, especially in combination with iron. I am not entirely convinced that it is of much more value in simple debility than is quassia or other simple bitters; but if, as is probable, it be true that quinine lessens to a very great extent the elimination of nitrogen, i.e., the consumption of tissue, the general practice is well founded. Dr. Hare (*Boston Med. and Surg. Journ.*, vol. cxiv, p. 73), as the result of observations made upon himself, believes that quinine has a distinct action in increasing the formation of the red blood-corpuscles. If this be correct, it must have especial value as a tonic.

When administered in very large doses, quinine, as has been already shown, acts as a powerful depressant, and as such it has been used by Briquet and other French physicians in *rheumatism*. As much as sixty or seventy grains a day have been given, and it is beyond dispute that under the influence of these heroic doses the symptoms of inflammatory rheumatism have often rapidly abated; but the method has found little favor out of France, and is less efficient and more dangerous than other plans of treatment now in vogue.

In *inflammatory rheumatism*, after the acute symptoms have abated, when the patient shows evident signs of weakness, especially if there be profuse sweating during sleep, fifteen grains of quinine daily are often of great service.

Quinine and its salts have the remarkable property of converting the chemical rays of the spectrum into light, or, in other words, of

rendering visible the ordinary invisible rays of the solar or other spectrum. Connected with this fact is probably the phenomenon known as the fluorescence of quinine. When a colorless watery solution of one of its salts is examined, a pale-blue line upon the surface is very noticeable; and Professor Stokes has shown that solution of quinine has the power of entirely stopping certain of the rays of light, so that when a beam is transmitted through it to light up a second vessel of the solution this latter displays no fluorescence. Dr. H. Bence Jones (*Lectures on Pathology and Therapeutics*, London, 1867) has found that when the electric light is used this test is so delicate that one grain of the alkaloid may be detected in 1,450,000 grains of water. He has also discovered that man and animals are pervaded by a substance which, in its action on light and in many chemical reactions, very closely resembles, if it be not identical with, quinine. Believing this substance to be probably an alkaloid, he has given it the name of *animal quinoidine*. Drs. Edward Rhoads and William Pepper, Jr. (*Pennsylvania Hosp. Reports*, vol. i., 1868), have made observations upon ten cases of malarial fever in which no quinine had been used, and have found the fluorescence of the blood to be from 0 to $1\frac{1}{2}$, instead of from 3 to 6, which is said to be normal. Dr. Chalvet (*Schmidt's Jahrb.*, Bd. cxli. p. 152) has, however, shown that this fluorescent substance exists in various foods, and is probably of vegetable origin, so that it is extremely unlikely that there is any pathological connection between the absence of the fluorescent body from the blood and malarial fever.

The researches of Laveran, of Marchiafava and Celli, of Osler, and of Councilman render it probable that malarial disease is caused by certain organisms in the blood. Of these organisms, at least three different forms have been detected. In one of these forms rapid multiplication by segmentation is going on. According to the investigations of Professor Osler, confirmed by Dr. Councilman, this segmenting organism is found only in or about the chill period of the acute malarial paroxysm. The second form of the organism is a quiescent crescent, which is found only in cases of malarial cachexia. The third supposed stage or form of organism is flagellate; but no connection has as yet been made out between this and any special stage of malarial poisoning. Dr. Councilman has found that fifteen grains of quinine given daily for several successive days usually arrest the paroxysm of an intermittent, and at the same time greatly lessen the number of segmenting organisms in the blood. In his cases after several daily doses of twenty-five grains the segmenting organism always entirely disappeared. No effect upon the crescentic organisms was produced by even excessive doses of quinine or of arsenic. As the value of these therapeutic agents in chronic malaria is thoroughly established, it is at present not possible to explain why they do not affect the crescentic organisms: it is indeed not altogether certain that these represent one of the life-stages of the segmenting organism and have etiological connection with malarial fever.

Quinine in its relations to *malarial fever* may be considered first as a prophylactic, secondly as a curative agent.

The value of the daily use of quinine to persons exposed to a malarial atmosphere has now been thoroughly tested in all portions of the world. In North and South America, in Europe, in Africa, in India, the prophylactic powers of quinine have been tried on the largest scale in connection with the military and naval services, and the testimony is unanimous in favor of the drug. A single citation will serve to illustrate this fact.* Dr. J. B. Hamilton (*Indian Medical Gazette*, Nov. 1, 1873) reports the case of a battery of one hundred and thirty-five men, quartered at Jubbulpore, East Indies, in the same barracks with an infantry regiment. Each of the artillerymen received three grains of quinine every other day; to the infantry none was given. The result was that while three hundred out of the five hundred men of the regiment were sick at one time with malarial disease, at no period was more than four per cent. of the battery affected. The dose of quinine as a prophylactic may be considered as three grains in the morning and two in the evening.

As long ago as 1831 an anonymous writer in Germany called attention to quinine as a specific in epidemic *cholera*, basing his argument upon the supposed malarial nature of the disease, since which date there have been published various papers claiming excellent results from the use of the remedy. (See *Quinine in Cholera*, by Erskine B. Fullerton, Columbus, Ohio, 1893.) Professor Fullerton believes that the remedy acts in the alimentary canal by inhibiting the growth of the cholera germ, and claims great value for it when given in doses of from fifteen to twenty grains in the course of two hours at the onset of the disease, also as a prophylactic.

In *intermittent fever*, when there is sufficient time, it may be well to precede the quinine by a mercurial or other purge. If the expected paroxysm be so near that there is not sufficient time for the action of the purgative, the antiperiodic should be administered without previous preparation of the patient. The value of purgatives in obstinate intermittents, as an adjuvant to quinine, is often overlooked, although in some cases the employment of purgatives, and of such diuretics as cream of tartar, seems to be almost essential for its successful use.

When there is necessity for prompt action, the antiperiodic may be given in a single dose, or in any other method that the circumstances of the case will allow; but ordinarily the best plan is to commence the exhibition of the drug about eight hours before the expected paroxysm, and to continue in hourly doses until from three to four hours before the attack is due.

In *pernicious fever*, or *malignant malarial poisoning*, no time should be lost after the first paroxysm in getting the patient cinchonized, as it

* See also K. M. Downie, M.B., *Indian Medical Journal*, March 1, 1872.

may be uncertain whether the attack be of the quotidian or of the tertian type. At least thirty-five grains of the alkaloidal salt should be administered during the first twenty-four hours of intermission, and twenty-five grains during the second; in very severe types of the disease much larger doses even than these are necessary, less than fifty grains of the drug sometimes appearing to do but little good.

In *remittent* or *bilious fever* it may often be advisable to give purgatives and febrifuges, but it is not proper to delay the exhibition of the antiperiodic on their account. As soon as the remission has appeared, the exhibition of quinine should be begun. Local inflammations or even severe cerebral symptoms occurring during a remittent fever are no contra-indications to the use of the specific. When gastritis exists, other channels of entrance than the stomach should be employed, on account of the local irritant action of quinine.

When the symptoms in remittent fever are severe and seemingly continuous, it may be not only proper, but necessary for the saving of life, to exhibit quinine freely during the period of fever. In large doses the alkaloid is probably antipyretic as well as antiperiodic, and I do not know of any theoretic or clinical objection to its use during the period of fever.

In *malarial intermittent neuralgia*, as in all other forms of abnormal manifestations of malarial disease, quinine is efficient, although it may be necessary to use it in large doses.

In *neuralgia* which, although not dependent upon malaria, assumes the intermittent type, quinine will often temporarily set aside the paroxysmal attacks, and sometimes effect a cure. The same fact may be stated in broad terms as true of *all non-malarial intermittent* affections. In the great majority of such cases, unfortunately, the action of the quinine is only temporary, and any controlling power is soon lost.

The amount of quinine required in ordinary cases of malarial fever and the method of its administration, have been the subjects of almost endless discussion. As the result of much experience and reading, I am convinced that it is better to use the remedy in large doses at intervals than to administer it continuously in smaller amounts. In this climate twelve grains of quinine a day will usually put an end to a mild intermittent, but the paroxysm will be very apt to recur, even if six grains of the alkaloid be afterwards given daily for some weeks. I believe it is better to administer from fifteen to twenty grains in the beginning, sufficient to produce very pronounced cinchonism and to arrest the disease at once. The full physiological effect of the drug should then be maintained for two or three days, and no more of it given except at regular intervals. The paroxysms have undoubtedly a great tendency to return on the seventh day after their arrest, and every seventh day for some weeks full cinchonism should be produced. If the observation of Councilman that large doses of quinine entirely

destroy the malarial organism be correct, the practice just spoken of has a foundation in scientific as well as in empiric observation.

Various idiosyncrasies exist towards quinine. Professor Karamitsas asserts that in some persons it produces hæmaturia (*Bull. Therap.*, xvii. 53): it not very rarely causes vesical irritation. In rare cases (*Brit. Med. Journ.*, ii., 1869; *Berlin. Klin. Woch.*, 1877, 294; *Phila. Med. Times*, x. 166) a few grains given internally suffice to cause great œdema of the face and limbs, accompanied with a pronounced erythematous rash, in some cases closely resembling that of scarlatina (*N. Y. Med. Record*, xxi. 627), the whole subsiding in a few days, with desquamation of the cuticle. I have myself seen two grains of quinine produce a furious general urticaria, with great subdermal swelling and cardiac depression, seriously threatening life: in this instance different members of the same family had the same idiosyncrasy. Purpura has also been ascribed to the alkaloid (*Boston Med. and Surg. Journ.*, cix. 587). Chevallier describes (*Gaz. des Hôpitaux*, 1850) a peculiar affection of the skin, etc., as occurring among workers in the bark.

Local Use of Quinine.—The effect of quinine upon the lower organisms has suggested its local use in various disorders supposed to depend upon the presence of such entities. Thus, Dr. Henke (*Deutsches Archiv für Klin. Med.*, Bd. xii. p. 630), finding some peculiar motile cells in the sputa of whooping-cough, employed inhalations of quinine with asserted good results. Dr. Henke was not, however, the first to suggest either this fungoid pathology of whooping-cough or the use of quinine. Professor Binz in 1870 (*Amer. Journ. Obstetrics and Diseases of Women*, iii.) claimed that quinine had a specific action in whooping-cough, provided it was given in large doses in solution, so as to come in contact with the mucous membrane in its passage through the pharynx; and in 1871 Letzerich (*Ibid.*, vol. iv. p. 761) announced that whooping-cough was due to a fungus in the lung. Professor Dawson (*Ibid.*, 1873) has confirmed the value of the method of Professor Binz; but, if the fungoid theory be—as I do not believe—true, the plan of Henke must certainly be the better one. The use in hay fever, as recommended by Helmholtz, of a weak tepid solution (gr. j to iii—fʒi), as nearly neutral as possible, freely applied to the nasal mucous membrane, has not achieved general recognition, and any influence which the alkaloid has in either whooping-cough or hay fever probably depends upon its direct influence upon the mucous membranes. In the later stages of gonorrhœa the topical employment of its solution (gr. v to x—fʒi) is often serviceable.*

ADMINISTRATION.—Owing to its bitter taste, sulphate of quinine is generally given in pill, which may be made with gum, or simply by

* Walerian Sokolow affirms that the local application of quinine to wounds has a very remarkable effect upon the granulation tissue, a similar effect being produced by the administration of the drug by the mouth. (For details, see *Inaug. Dissert.*, 1891, abstracted in *Schmidt's Jahrb.*, 1892.)

adding a little sulphuric acid to the alkaloidal salt and quickly rubbing up the pasty mass into pills before it hardens. When a rapid action is desired, the quinine should be given in powder, or in solution made by adding a drop of dilute sulphuric acid for every grain of the salt. In the use of pills of quinine, care should be exercised to see that they are soft and fresh, for when old and hard they not unfrequently pass through the bowels unchanged. The ready-made "sugar-coated" pills kept in the shops should be avoided, as uncertain in their action. The taste of the powder is best covered by chocolate or by liquorice.

When sulphate of quinine is given *hypodermically* it acts with much greater promptness and apparently with greater force than when administered by the stomach. Albertoni and Ciotto (*Bull. Thérap.*, xc. 403) found that when they injected it into the jugular vein it failed to appear in the bile, but when they administered it by the mouth it was freely eliminated with that secretion. Biliary salts of quinine are so insoluble that their reabsorption must be effected, if at all, very slowly: hence possibly the superior efficiency of the hypodermic method. The local irritant action of quinine, however, forbids its hypodermic employment except in cases of great emergency. Given in this way, it very generally produces great local disturbance (abscesses, ulcers, etc.), and in several cases has caused fatal tetanus (*Lancet*, 1876, i.). When it is so given, care should be taken to have an excess of acid (tartaric is the best) in the solution, to prevent precipitation of the quinine by the alkaline juices of the cellular tissue. *Quinine Bisulphate* (*Quinina Bisulphas*, U.S.) is soluble in ten parts of water, and should be preferred for hypodermic use: even its solution should be slightly acidulated. Ten grains of quinine injected under the skin are probably equivalent to fifteen grains given by the mouth.

Contra-indication.—On account of its irritant properties, quinine must be used with caution when there is irritability or inflammation of any part of the gastro-intestinal tract. It is strongly contra-indicated by inflammation of the middle ear, and may greatly and permanently increase dulness of hearing. The statement of Dr. M. Friedmann (*Wien. Med. Presse*, 1884) that ergotin, and that of W. B. Dewees (*Univ. Med. Mag.*, 1890) that chloral greatly lessens the tinnitus aurium produced by quinine and salicylic acid need confirmation. Any irritation of the genito-urinary tract counter-indicates the use of quinine, and the affirmation of Dr. R. S. Williams that in *malarial hæmaturia** quinine in-

* In certain regions of country persons suffering from malarial poisons have intermittent attacks of hæmaturia, or probably, to speak more correctly, of methæmoglobinuria, in which the hæmaturia has been attributed by many practitioners to the influence of the sulphate of quinine. The facts, however, that quinine never produces methæmoglobinuria in healthy individuals, that the attacks are accompanied with chill, fever, and sweat, following, according to Carreau, absolutely the course of the paroxysm of intermittent fever, and that, though quinine is used everywhere, the methæmoglobinuria occurs only in certain localities, certainly seem to prove that the attacks are really due to a peculiar form of malaria and not to the quinine. The most elaborate account I have met with is that published in Guadeloupe, in

creases the bleeding from the kidneys (*Progress*, vol. iii., 1888-89), and should be avoided, challenges investigation.

Quinine Hydrobromate (*Quinina Hydrobromas*, U.S.) is soluble, at 59° F., in fifty-four parts of water and in 0.6 part of alcohol. It is stated that a ten-per-cent. solution in a mixture of twenty-five parts of alcohol and seventy-five parts of water is not irritant when used hypodermically.

The *tannate of quinine*,* although not officinal, has been used to some extent, and is certainly not inefficient. It has the great advantage of not being disagreeable to the palate, but is less active and less certain than the more soluble salts of the alkaloid, and is also much slower in its operation. If given at all, it should be in doses one-third greater than those of the sulphate.

The *double bimuriate of quinine and urea*, although not official, has been used to a considerable extent for hypodermic injections. It is said that a fifty-per-cent. watery solution, when thrown into the cellular tissue, produces very slight local irritation. It is also affirmed to contain about sixty-one per cent. of the alkaloid, and it is certainly capable of producing cinchonism.

QUINIDINÆ SULPHAS, U.S.—*Quinidine sulphate* occurs in long, shining, silky, acicular crystals, soluble in one hundred parts of water at 59° F., in seven parts at 212°, readily soluble in alcohol, nearly insoluble in ether. It is a basic salt, like the sulphate of quinine, readily taking another equivalent of acid. It behaves like its isomer with chlorine and ammonia, but is distinguished by rotating light powerfully to the right, instead of moderately to the left. It probably closely resembles quinine in its physiological and therapeutic properties, and is an efficient antiperiodic: the dose is about one-third larger than that of quinine.

Dextro-quinine, a brown, amorphous substance, derived from chinoidine, is said to answer all the tests for quinine except to polarize to the right. It is probably an impure quinidine.

CINCHONINÆ SULPHAS—CINCHONINE SULPHATE. U.S.

The pure alkaloid cinchonine crystallizes in prisms and needles. The official *cinchonine sulphate* is in short oblique prisms of a very bitter taste, soluble, at 59° F., in sixty-six parts of water, more freely in

1891, by Dr. J. Carreau (*Le Méthémoglobinurie Quinique*, 1891; see also Dr. Coromilas, *Bull. Soc. de Méd. Pratique de Paris*, 1891). Dr. Pispiris (*Le Progrès Méd.*, xix., 1891) affirms that in some cases of malarial fever not only the internal administration but also external friction of the sulphate of quinine will provoke serious gastro-intestinal hemorrhage. It does not, however, appear probable that the quinine in his cases was the cause of the bleeding.

* For an elaborate discussion of the therapeutic value of this salt, see *Bulletin de l'Académie*, Paris, 1872.

boiling water, readily soluble in alcohol. From its solution in chlorine-water it is precipitated white by ammonia. Bill's test for it consists in adding the ferrocyanide of potassium in slight excess to its solution. A yellowish white curdy precipitate is the result. On gently heating, this redissolves, but is again deposited, when the liquid cools, as abundant golden-yellow crystals.

PHYSIOLOGICAL ACTION.—Conzen (quoted by Husemann) has found that the action of cinchonine on infusoria and on fermentation is similar to but weaker than that of its sister alkaloid, and that on the movements of the white blood-corpuscles its influence seems transient. Laborde states that pure quinine does not cause epileptiform convulsions in the lower animals, although commercial quinine does so on account of its impurity, and that in poisoning with cinchonine violent epileptiform convulsions are a chief symptom (*Compt.-Rend. Soc. Biolog.*, iv. 1882). M. Bochefontaine (*Compt.-Rend. Acad. Sci.*, t. xcvi. p. 503) affirms, however, that quinine does convulse, although less actively than does cinchonine, which latter alkaloid he found to vomit less than quinine. According to Johnsen, the effect of cinchonine upon the elimination of urinary solids is even more powerful than that of quinine. It is eliminated unchanged, appearing in the urine in half an hour, and disappearing after massive doses only in ninety-six hours,—the great bulk being thrown off in the first twenty-four hours (*Pflanzenstoffe*, p. 1480). In Bochefontaine's experiments the relative strength of cinchonine to quinine was about 10 to 16 (*Ibid.*, p. 506); in Bernatzik's (on dogs only) as 4 to 5.

THERAPEUTICS.—As an antiperiodic, cinchonine exerts a similar influence to quinia, but is probably about one-third weaker than that alkaloid, and must be used in correspondingly larger dose. Dr. J. B. Hamilton (*loc. cit.*) affirms as the result of experiment that cinchonine as a prophylactic against *malaria* is even superior to quinine. As a tonic I have never been able to perceive that cinchonine acts differently from quinine.

CINCHONIDINÆ SULPHAS, U.S.—*Cinchonidine sulphate* occurs in white, silky, lustrous needles or prisms, odorless, of a very bitter taste, soluble in seventy parts of water, freely soluble in acidulated solutions. It polarizes to the left, and is not fluorescent. G. See and M. Bochefontaine found that the lethal dose of cinchonidine for the frog is 0.015 gramme; for the dog, 2.50 grammes. The symptoms in the dog are general feebleness, titubation, increase of pulse-rate and arterial pressure, vomiting, salivation, convulsions,—less severe than those caused by quinine,—great loss of muscular power, stupor, fall of arterial pressure and of temperature, death from arrest of respiration (*La France Méd.*, 1883, 527). A boy aged five years took one hundred and twenty-eight grains in solution during six hours without vomiting. There were then convulsions, followed by great collapse, fall of temperature, pulselessness (with seventy-four cardiac beats per minute), dilated

pupils, muscular relaxation, and, finally, death; consciousness was preserved to the end (*N. Y. Med. Journ.*, xxxix. 1884). It is evident that this alkaloid closely resembles its congeneric alkaloids in its action upon the human organism. Clinical experience has proved it to be a reliable tonic and antiperiodic. According to Byasson, it is eliminated by the kidneys unchanged. It has been claimed that it produces less disagreeable symptoms, both gastric and cerebral, than does quinine; but Dr. Rafferty, who has administered three hundred ounces of the sulphate, affirms that it is more apt to cause nausea and vomiting. The dose is one-third greater than that of quinine. Dr. De Sograis has found the *bromohydrate* given hypodermically in doses of 4 to 6 grains very efficacious (*Arch. G n rales*, xvii. 711).

CHINOIDINUM. U.S.—*Chinoidin*, or *Quinoidin*, is a blackish substance, with an almost resinous fracture, which is obtained by the evaporation of the mother-liquor after the crystallization of the alkaloids out of it. This substance contains probably amorphous quinine and cinchonine, besides quinidine and cinchonidine. It is an excellent tonic and antiperiodic, and, on account of its cheapness, is largely used in some of the eleemosynary institutions of this city. It should be administered in about double the dose of quinine, and is most efficient in solution, but, on account of its taste, is often given in pills. Its solution should be made with acetic acid and water, aromatics being freely added, as it is apt to cause nausea.

The U.S. Pharmacopœia recognizes for use as a tonic an infusion of bark (*Infusum Cinchonæ*—6 per cent.), dose, a wineglassful; a tincture (*Tinctura Cinchonæ*—20 per cent.), dose, one to two teaspoonfuls; a compound tincture (*Tinctura Cinchonæ Composita*—10 per cent.—*Huxham's Tincture*), which, as a tonic, is the best preparation of the bark, and is a very elegant remedy in convalescence, in doses of one teaspoonful to a tablespoonful; also a *fluid extract* and a *solid extract* (*Extractum Cinchonæ Fluidum* and *Extractum Cinchonæ*), the doses of which are five to fifteen drops or grains respectively.

CINCHONAMINE.—This alkaloid was discovered by Arnaud (*Compt. Rend.*, vol. xciii.) in the *Cuprea* bark from Colombia, probably the product of *Remijia pedunculata* and *Remijia Purdieana*. Its physiological action has been partially investigated by S e and Bochefontaine (*Compt. Rend.*, vol. c.). In poisonous doses it produces violent convulsions in the dog, with fall of the arterial pressure. It also arrests the heart in diastole, and increases especially the secretion of the salivary glands. Its influence upon man has not, so far as I am aware, been studied, but its botanical and chemical relations make it probable that it resembles quinine in its physiological and therapeutical properties.

WARBURG'S TINCTURE.—This is a dark-brown liquid, prepared in accordance with a very complicated formula,* which has obtained an extraordinary reputation in India and other tropical countries in the treatment of severe *remittent* and *malignant malarial fevers*. The testimony is so strong as to its remarkable and almost certain efficiency that it cannot be questioned, and entitles the tincture to rank above all other remedies. The method of administration is as follows. The bowels having been freely opened, a half-ounce of the tincture is given undiluted, all drink being withheld, and at the end of three hours a second half-ounce is in similar manner exhibited. Soon after the last dose a profuse and very aromatic perspiration sets in, and convalescence is usually secured. The remedy is also commended in one-drachm dose in acute *nervous exhaustion* and *collapse* without organic disease.

EUCALYPTUS. U.S.

The *Eucalyptus globulus*† is a large tree, native of Australia. The leaves, which are alone officinal, contain, besides tannic acid, a volatile oil, which, when pure, is nearly colorless, of a warm, mint-like taste, with a bitter after-taste, and a peculiar mint-like odor. This oil is freely soluble in ether, alcohol, and the fatty oils, and is obtained by distillation or by acting on the leaves with ether. It does not undergo oxidation into a resinous mass on exposure to the air, and is remarkable for its power of resisting the influence of concentrated sulphuric acid. It has been affirmed that the leaves of *Eucalyptus* contain also an alkalioid; but Rabuteau (*Bull. Thérap.*, lxxxiii. 549) has demonstrated that this is an error. All the virtues of the remedy probably reside in the

* For formula, see *Med. Times and Gaz.*, 1875, ii. 541; or *Phila. Med. Times*, vi. 126; or *London Practitioner*, xviii. 62.

† Attention was first called by Labillardière in 1792 to the value of the *Eucalyptus globulus*, but it was not until 1860 that M. Ramel commenced the culture of the tree in Paris and induced the Prefect of the Seine to order its cultivation on a large scale. Since that time it has been largely introduced into Europe, Algeria, South Africa, and California, and in some of these countries planted forests are now growing and spreading. The tree is remarkable for combining extreme hardness of wood with a rapidity of growth asserted to be about five times that of our ordinary trees; it is even affirmed that shingles made of it are fire-proof. Its capability for absorbing and evaporating water is extraordinary, and to it has been attributed the freedom of Australia from malarial climatic influences. Indeed, it is stated that a tree will evaporate ten times its weight of water in twenty-four hours, and numerous examples are given in which swamps in Europe and Algeria have been rapidly converted by it into dry ground. It is believed to destroy malaria not only by draining the soil, but also by yielding balsamic exudations to the air: however this may be, there is at present very strong evidence as to its power of rendering infected districts healthy. As, however, the consideration of this belongs to the subject of hygiene rather than of therapeutics, the reader is referred for detailed information to the following memoirs: *Regulus Carlotti, L'Eucalyptus, son Rang parmi les Agente de la Matière Médicale*, Ajaccio, 1872; M. Gimbert, *L'Eucalyptus Globulus, son Importance en Agriculture, en Hygiène et en Médecine*, Paris, 1870; Waterer, *Bulletin de la Société d'Acclimatation*, 1872; *London Medical Record*, Dec. 1873; *London Lancet*, ii., 1877.

Under the name of *Eucalyptintha*, a liquor distilled from the leaves of the *Eucalyptus* has appeared in European commerce.

volatile oil, which is in greatest abundance in the leaves. According to the researches of Stanislas Martin (*Bull. Thérap.*, lxxxiii. 453), the oil is entirely absent from the bark of plants grown in Southern France and Corsica, but exists in that from Australia and Algeria.

PHYSIOLOGICAL ACTION.—Locally, the oil of Eucalyptus acts as a decided but not very intense irritant, and the first effect of large doses is burning in the mouth and fauces, with increased secretion of saliva, followed very soon by a feeling of warmth in the stomach.

The general effect of the same dose of the oil appears to vary considerably in different individuals; but the following summary comprises the facts as nearly as may be. After the ingestion of from ten to twenty drops, a period of mental and physical activity is often apparent, followed by a feeling of calm and serenity. By larger doses, or in susceptible persons by the doses mentioned, there is caused increased disturbance of the digestive organs, ending often in loose stools having the odor of the oil, with augmentation in the frequency and force of the pulse. Gubler adds to these symptoms an increase of temperature; but in Gimbert's experience febrile manifestations, although occasionally occurring, were not usually present. In some cases the medicine acts very disagreeably, producing violent cardiac palpitations or intense headache: how far these are directly dependent upon the drug, or are sympathetic upon its local action on the stomach, is uncertain. If the dose be repeated, or if a larger amount be taken at once, a period of sedation manifests itself; the pulse loses its force, and the animal temperature is abated. After doses of seventy-five grains, Binz noted numbness of the limbs, with a feeling of excessive weight in them. If the use of the remedy be persisted in, a state of asthenia is induced; the temperature falls as much as a degree and a half, and the pulse even to fifty (Gimbert, *Archives Générales*, 1873, xxi. 141); the respiration becomes less frequent, and the muscular weakness extreme, so that raising the arm to the mouth is painful; the sensations are blunted, but the intellect is absolutely unaffected. In an old man who took eighty drops, the power of motion almost disappeared, and he affirmed that he lost for the time being all sense of the presence of his limbs, so that he was unconscious of possessing them when he shut his eyes, although his intellect was perfectly clear throughout. In a case reported by Dr. Alfred Neale (*Australian Med. Gaz.*, xii., 1893), a little over half an ounce of the oil of Eucalyptus is said to have produced death in fifteen hours in a healthy boy: the only recorded symptoms were violent dyspnoea with collapse.*

Upon the lower mammalia the oil of Eucalyptus appears to act precisely as it does on man. According to the experiments of Gimbert, the hypodermic injection of the oil is immediately followed by a period

* As a quart of very bloody serum was found in the pleural cavity, and as the boy was not seen professionally until he was in *articulo mortis*, much doubt attaches to this case.

of excitement, seemingly in great measure due to the intense local irritation; after about half an hour, if the dose has been sufficiently large, the animal begins to stumble and totter in walking, the breathing grows more and more slow and irregular, the limbs give way, the ears droop, the muscular weakness becomes profound, and death, preceded often by partial convulsions, occurs through failure of respiration. In Gimbert's experiments the heart always continues to beat after breathing had ceased. As the motor nerves and the muscles retained their functional power after death, the failure of motility and reflex activity must have been central, and Gimbert concludes that the drug in toxic doses is therefore a *paralyzant to the spinal cord and the medulla*. This conclusion was also attained experimentally by Binz (*British Medical Journal*, i., 1874). Various observers accord in stating that after toxic doses there is, in animals, a decided fall of temperature. It would appear from the experiments of Hermann Schlager that after hypodermic injections the temperature sometimes rises, probably as the result of the local irritation (*Die Physiol. Wirk. d. Eucal. glob.*, Inaug. Diss., Göttingen, 1874). The same observer noted that the arterial pressure was greatly lessened. As this fall occurred after paralysis of the par vagum by section or by atropine, and also after vaso-motor paralysis by section of the cord, it must be due to a *direct action upon the heart*. This was confirmed by the direct influence of the drug upon the cut-out heart of the frog. The oil is probably eliminated by the lungs, skin, and kidneys. In the experiments of Professor Binz, the day after the ingestion of seventy-five drops the breath smelt of the drug, and the perspiration of amylic alcohol. The urine began to have the odor of the oil an hour and a half after its ingestion, and continued to have it for thirty-six hours. Dr. Gimbert states that the odor imparted to the urine resembles that of violets, and is very similar to that caused by turpentine.

Binz states that upon the lower infusoria the oil acts even more powerfully than does quinia; and its antiseptic properties are without doubt very great (Gimbert, *Archives Générales*, xxi. 137). Mosler (*Deutsches Archiv f. Klin. Med.*, 1872, x. 160) affirms that in dogs whose spleens were exposed, injections of tincture of the leaves of Eucalyptus produced a decided contraction of the viscus. According to Gimbert, the excretion of urea is enormously increased by the use of the drug.

THERAPEUTICS.—The chief use that has been made of Eucalyptus is as an antiperiodic. So far as I know, Dr. Joseph Koller (*Wiener Medizinische Wochenschrift*, xxii., 1872) has employed it upon a larger scale than any one else. He used it in four hundred and thirty-two cases, of which two hundred and ninety-three had suffered from previous attacks. Of the tertians 75.57 per cent., of the quartans 70 per cent., and of the quotidians 67.89 per cent. yielded to the remedy. He recommends it as especially valuable in obstinate cases in which quinine has been taken again and again. Lorinser (*Wiener Medizin. Wochen-*

schrift, xix., xx.), Haller (*Wiener Medizin. Wochenblatt*, xxvi.), Bohn (*Berlin. Klin. Wochenschrift*, 1872), Carlotti (*loc. cit.*), Cortan (*Montpellier Medical*, May, 1872), Gimbert (*loc. cit.*), Gubler (*loc. cit.*), Tristany, of Spain (*Buchner's Repertorium*, xix., 1870), J. H. Musser (*Therap. Gaz.*, 1886, 369), and others, bear testimony to the value of Eucalyptus in malarial diseases; while Brudell (*Bulletin Thérapeutique*, May, 1875), Seitz (*Bayer. Aerzt. Intell. Blatt*, 1870), and Papillon (*Gazette Hebdomadaire*, 1872) affirm it to be of little or no value. The weight of testimony is in favor of the possession of decided antiperiodic powers by Eucalyptus, and where the cinchona alkaloids have failed, or for any reason cannot be taken, it ought to be tried. Oil of Eucalyptus (*Oleum Eucalypti*, U.S.) is also one of the best stimulating expectorants that we possess: in both acute and chronic bronchitis it may be exhibited when there is free secretion. I have found that children bear it very well in proportionally large doses. From one-half to one drachm a day may be given, in divided doses. The fluid extract (*Extractum Eucalypti Fluidum*, U.S.) may be given in doses of from five to ten minims.

ACIDUM PICRUM—PICRIC ACID.*

Picric or *Carbazotic Acid* is not officinal, but has been used to some extent in medicine. It occurs in pale-yellow, shining scales, but is employed by the therapist only in the form of a salt, on account of the deleterious influence of the pure acid on the gastric mucous membrane: the picrate of potassium, of sodium, or of ammonium may be used; but the last is the one generally chosen.

Physiological Action.—The only detailed study of picric acid known to me is that of Dr. W. Erb (*Die Pikrinsäure*, Würzburg, 1865). This observer found that the daily use of a grain (for ninety days) of a picrate produced, in a rabbit, yellowness of the conjunctiva, of the inner surface of the ear, and of the urine, with an occasional slight diarrhoea and great loss of weight, without any elevation of temperature. After a time the animal seemed to grow accustomed to the remedy, so as to regain in great measure its flesh. Three grains a day caused, in about two weeks, the death of the rabbit, with symptoms of inanition. All the tissues, except the nervous, were stained of an intense reddish-yellow color, as was also the urine. Eight grains produced falling temperature, weakness, diarrhoea, collapse, and death, sometimes preceded by tremblings and even by convulsions, in about twenty-three hours. Most of the tissues were stained yellowish red. The most remarkable physiological effect of the poison occurred in the blood. The blood of animals slowly killed by a picrate was of a dirty-brown color, with distinct nuclei both in the red blood-disks and floating free in the serum. Dr. Erb found that this alteration in the cor-

* Picric acid scarcely belongs in this chapter, but, as it has attracted most attention as an antiperiodic, in the ignorance which exists as to its physiological action I have here introduced it.

puscles occurred during life and was accompanied by a decided increase in the number of the white corpuscles. These alterations in the blood were apparently the cause of death, and seem to have been due, so far at least as concerned the red disks, to a direct action of the poison upon the blood; for Erb found that identical or very similar alterations occurred in these corpuscles when the blood was mixed with the picrate of sodium outside of the body. Dr. Von Beck (*Charité-Annalen*, xvii., 1892) reports urticaria and measles-like eruptions produced by the prolonged use of the ammonium picrate.

Erb found picric acid to act on man as on the lower animals. Twenty-four hours after the ingestion of fifteen grains of it the yellow color was very plain in the conjunctiva, the skin, and the urine. The temperature was not elevated, and gastric disturbance was usually absent, but sometimes it was severe. As in animals, so in man, picric acid was found abundantly in the urine. A teaspoonful produced no more violent symptoms in a man than bad vomiting and purging (*Wiener Med. Presse*, xxiii. 1526).

Professor Binz (*Virchow's Archiv*, Bd. xlvi. p. 130) has found that picric acid exerts upon the infusoria an influence similar to, but much feebler than, that of quinia.

THERAPEUTICS.—The carbazotate of ammonium has been strongly recommended by various authorities in malarial disorders; but in the experiments of Erb the result was so negative that the possession of any antiperiodic powers by the drug is doubtful,* although Mr. H. M. Clark (*Lancet*, i. 1887) affirms that he has treated with it ten thousand cases of malarial disease with such good results that he has abandoned the use of the cinchona alkaloids. He gives from one-eighth to one-half grain four times a day in pill,—one-third of a grain being the average dose. As an *anthelmintic*, the picrate has also been commended; but Erb found it powerless in cases of *tænia*, and for the destruction of the round-worm and thread-worm there is an abundance of safer and even more efficient remedies. A matter of the gravest importance is the asserted efficiency of the remedy in *trichiniasis*. Erb has produced slow poisoning with a picrate in rabbits which had been fed upon affected meat, and, on examining their bodies after death, found the trichina everywhere, even in the walls of the intestines, in very active life. On the whole, the testimony so far seems to indicate that picric acid has no value as a therapeutic agent, unless, indeed, Dr. Graeme Hammond be correct in affirming (*New York Med. Journ.*, Jan., 1890) that it is a specific in *exophthalmic goitre*. Erb states that in robust adults from nine to fifteen grains a day may be given for a long time with safety; but I should fear the effects of more than half that quantity.

FAMILY V.—ANTIPYRETICS.

ACIDUM CARBOLICUM—CARBOLIC ACID. U.S.

Phenic Acid, Phenylie Alcohol, is a substance obtained from coal-tar by distilling at a temperature of between 300° and 400° F., adding to the distillate a hot concentrated solution of potassa, and, after this, water, separating the light oily matters which rise to the top, and adding muriatic acid to the heavy alkaline bottom layer, when impure carbolic acid separates. This impure carbolic acid (*Acidum Carbolicum Crudum*, U.S.) is of a dark color, and contains several congeneric bodies, especially xylie and cresylic acids.* For disinfectant purposes these appear to be at least of equal value with the carbolic acid, and therefore the crude product of the above-detailed process is very largely used. Carbolic acid is separated from its allies and obtained in a pure state with some difficulty, by a process too complex to be discussed here. When finally procured, it occurs at ordinary temperatures in minute, colorless, transparent plates, or long rhomboidal needles, often fused into a mass, having a hot, corrosive, peculiar taste and a peculiar odor, resembling but decidedly different from that of creasote. If, on exposure to the air, phenic acid becomes brown, it contains impurities. When opportunity is afforded, solid carbolic acid absorbs water from the atmosphere and melts into an oily-looking, colorless liquid. It is inflammable, neutral to test-paper, but combines with bases; soluble in about twenty parts of water, very soluble in alcohol, acetic acid, ether, glycerin, and the volatile and fixed oils. Nitric acid converts it into picric acid.

PHYSIOLOGICAL ACTION.—Carbolic acid is exceedingly poisonous to all forms of life, from the lowest to the highest. Much of its employment in medicine depends upon its action on infusoria and fungi; and

* *Cresol, Cresylol, or Cresylic acid*, boiling at a temperature higher than carbolic acid, is a later product of the fractional distillation of coal-tar. It is undoubtedly a very powerful antiseptic, and Henri Delpianque (*Thesis*, Paris, 1898) affirms that it is much stronger in its germicidal influence than carbolic acid, and only one-quarter as strong as a poison to the higher animals. It forms with sulphuric acid a compound which is odorless, soluble in water, and, according to Frankel (*Zeitschr. f. Hygiene*, 1889), scarcely irritating, a four per-cent. solution being readily retained in the mouth. The experiments of Frankel have led him to the conclusion that *cresol-sulphuric acid* is much more powerful as a disinfectant than is carbolic acid. If these claims be correct it ought to have value in practical medicine.

yet its direct internal and external use in human medicine is quite large. Its physiological action is therefore to be viewed from two distinct stand-points: first, its influence upon the higher animals and man; secondly, its action on the lowest animal and vegetable forms.

According to Dr. Isidor Neumann (*Archiv f. Dermatol. u. Syphilog.*, Jahrgang i., 1869, p. 425), to Dr. Ernest Labée (*Archives Gén.*, 6e sér., t. xviii. p. 451, 1871), and to Salkowski (*Pflüger's Archiv*, Bd. v., 1872), when a poisonous dose of carbolic acid is given to a frog there is produced a paralytic condition which usually affects first the hind legs,* but eventually spreads to the front legs and involves all parts of the body. After a time there are developed tetanic convulsions, which are apparently reflex in their nature, and are said to be excited by external stimuli or irritations.

Carbolic acid acts upon mammals in very much the same way as upon the batrachian. According to W. Kempster (*Amer. Journ. Med. Sci.*, July, 1868), in the mouse and rat it causes intense muscular weakness, followed by violent convulsions and stupor. In the rabbit (Neumann, Salkowski), phenylic alcohol produces muscular weakness, often accompanied by tremblings and restlessness, at last giving place to violent convulsions. Before these have fairly set in, the animal is generally unable to stand; and during them he lies on his side, kicking into mid-air. Early in the poisoning the respiration is very much affected; and the death, which usually occurs in the midst of convulsions, appears to be owing to a *paralysis of the respiration*, since in acute cases the heart is found beating continuously immediately after death. According to the researches of Dr. Jules Lemaire (*De l'Acide Phénique*, 2d ed., Paris, 1865), in the dog symptoms very similar to those detailed above are caused by lethal doses of the drug; and Husemann (*Schmidt's Jahrb.*, Bd. clv. p. 274) states that in mammals and in birds the characteristic phenomena of carbolic acid poisoning are clonic convulsions, sinking of the temperature, diminution of sensibility, dyspnoea, free salivation and secretion of tears, keratitis, and conjunctivitis. According to the latter authority, albuminuria and hæmaturia are occasional phenomena. Upon man carbolic acid acts as upon other mammals. Reserving the details for the section on Toxicology, it is sufficient for our present purpose to state that the prominent symptoms induced by lethal doses are disturbance of respiration, coma, muscular weakness, and, in some cases, convulsions. A closer investigation of the action of large doses of carbolic acid is best made by studying the effects upon the different systems *seriatim*.

Nervous System.—Upon the cerebrum phenylic alcohol appears to exert a direct influence, which, although not very intense in the lower animals, in the higher species, and especially in man, results in the early production of stupor.

* According to Lemaire, when a frog is allowed to swim in water impregnated with carbolic acid, the front legs are the first affected.

The convulsions are not peripheral, since they do not occur in a limb whose connection with the spine has been severed by division of the nerve, and do take place in a leg which has been protected against the local action of the poison by tying the artery (Salkowski, Labée). They are, therefore, either cerebral or spinal. Although there is a distinct conflict of evidence, it seems to me established that they are of *spinal origin*. Labée and J. R. Haynes failed to get them after section of the cord, but in the far more numerous experiments, upon frogs and mammals, of Salkowski, of Berb and Jogel (*Gaz. Med.*, 1872), of J. S. Stone (*Phila. Med. Times*, ix.), and of T. Gies (*Arch. f. Exper. Path. u. Pharm.*, xii. 401), convulsions occurred after destruction of the medulla, section of the cord, and other operative procedures separating the brain from the lower nervous system. The failures of the first-named experiments are explainable by the facts that the paralyzing influences of carbolic acid are usually first manifested upon the hind legs, and that very large doses of the acid were employed. The spinal convulsions are accompanied by increased reflex activity, which is lost as the paralytic state is reached, so that carbolic acid appears *first to stimulate and then depress the spinal centres*. Stone asserts that the stimulation is preceded by a primary depression, due to stimulation of Setschenow's inhibitory centre in the medulla.

In carbolic acid poisoning the nerves and muscles are not distinctly paralyzed, galvanic stimulation of a nerve after death eliciting vigorous response in the tributary muscle (Salkowski, *loc. cit.*, p. 338; Hoppe-Seyler, *loc. cit.*, p. 476); but the very careful experiments of Gies (*loc. cit.*, p. 413) have proved that such muscles are less sensitive and more easily exhausted than in the unpoisoned animal.

Circulation.—The action of carbolic acid upon the heart is not a very marked one, but there can be little doubt that in sufficient amount the drug *depresses the heart*. After death from acute poisoning the heart is usually found to be beating regularly (Salkowski), but in some cases of slow poisoning the death has seemed to be ultimately caused by cardiac diastolic arrest. In Hoppe-Seyler's manometrical studies (*Pflüger's Archiv*, 1872, v. 475) the arterial pressure was not affected until convulsions came on, when it rose from the effects of the general muscular contraction. It afterwards fell very decidedly, and permanently. Reduction of the arterial pressure has been shown by Gies to be the characteristic effect of the carbolic acid: in his experiments moderate doses of the acid failed to affect the pressure after section of the cord, whilst in the normal animal neither asphyxia nor stimulation of a sensitive nerve elevated the lowered pressure, although the heart was beating forcibly,—facts that demonstrate that carbolic acid *paralyzes the vaso-motor centre* in the medulla before it markedly affects the heart.

Respiration.—According to Salkowski (*loc. cit.*, p. 344), Labée, and other authorities, in the first stages of carbolic acid poisoning the respi-

ration is remarkably increased in frequency. This acceleration Sal-kowski believes to be due partly to a stimulant action upon the peripheral vagi, and partly to a similar influence upon the respiratory centres. He states that the respirations are very shallow, and that the diaphragm scarcely participates at all in them, but that if the cervical vagi be cut they become much slower, deep, and regular. On the other hand, if carbolic acid be given to an animal suffering from section of the pneumogastrics, the slow breathing is very much accelerated. From the former of these facts the German investigator draws the conclusion that the accelerated breathing produced by phenylic alcohol is in part due to a stimulation of the peripheral vagi, and from the latter fact that it partly arises from a similar action upon the respiratory centres.

Temperature.—According to the researches of Dr. Hobart A. Hare (*Therap. Gaz.*, 1887, 519), carbolic acid injected into rabbits produces a very distinct fall in the bodily temperature, which is usually but not always coincident with the lowering of the arterial pressure. In the calorimetric studies made by Dr. Hare the effect upon heat-production and heat-dissipation in the normal animal appeared to be various, sometimes production and sometimes dissipation being alone affected, while in other cases both functions were altered. Some years ago, Emil Erls (*Schmidt's Jahrbücher*, Bd. clxiv. p. 148) found that in mild putrid poisoning in animals carbolic acid diminished greatly the fever-heat; when the poisoning was more severe it had no influence. The calorimetric studies made by Dr. Hare upon febrile animals were fairly constant in their results, although the method of experimentation was not satisfactory, because the acid was given to the febrile animals at a time when it was uncertain what would have been the production of heat without its influences (see foot-note, p. 627.) Nevertheless the experiments indicate that carbolic acid may affect the thermogenetic functions of the body in two ways: first, by diminishing the production of heat; secondly, by increasing the dissipation of heat.

In sufficient concentration carbolic acid seems to be poisonous to all forms of protoplasm. Dr. T. M. Prudden (*Amer. Journ. Med. Sci.*, lxxxi. 82) finds that in strong solution it paralyzes, in weak solution depresses, the movements of the batrachian white blood-corpuscles and ciliated cells; and Labée has determined that outside of the body it materially affects the blood of mammals. Both Labée and Hoppe-Seyler (*Pflüger's Archiv*, v. 476), however, affirm that the blood of higher animals poisoned by carbolic acid presents nothing abnormal: so that the symptoms it produces must be the result of a direct influence upon the various tissues.

Post-mortem examinations of animals killed by carbolic acid have yielded varying results. In Lemaire's investigation, nothing abnormal was found except intense injection of the alimentary mucous membrane, a pseudo-membranous and purulent inflammation of the bronchial tubes, with a disseminated lobular pneumonia or else congestion

of the lungs and of the nerve-centres. Professor Bruckmüller, in Neumann's investigation (*loc. cit.*, p. 429), found the cells of the liver and kidneys in a state of fatty degeneration. This process, which seemingly was the counterpart of the changes in phosphorus-poisoning, was always more advanced in the kidneys than in the liver. Dr. Neumann states that it was always present in his numerous autopsies, and that it is a constant phenomenon; but Salkowski (*loc. cit.*, p. 273) was unable to find it in a number of examinations. In man, the post-mortem appearances are very much the same as in animals. If the acid has been ingested in a concentrated form, white, hardened spots are found upon the mucous membrane of the mouth, œsophagus, stomach, and even intestines. They are, of course, due to the local action of the poison, and are sometimes blackish in the centre, or even blackish throughout, and very generally are surrounded by a red inflammatory zone. The liver, spleen, kidneys, and indeed all the organs, are found filled with dark, imperfectly-coagulated blood, such as is habitually found after death from asphyxia. According to Husemann, the fatty degeneration of the liver and kidneys is not either in man or in animals a constant or characteristic phenomenon of carbolic acid poisoning. Renner found the renal epithelium degenerated in a man who had been fatally poisoned by the drug (*Journ. de Pharm. et de Chim.*, p. 456, Dec. 1871).

As the internal use of carbolic acid in such diseases as gangrene of the lungs is so closely connected with the question of its chemical history in the system and its elimination from the body, the latter is of very great interest. Since carbolic acid coagulates albumen, its absorption unchanged into the blood would seem a matter of doubt: yet in some form or other it certainly is absorbed, as is proved by the history of its elimination and by its having been found in the blood (Hoppe-Seyler, *Pflüger's Archiv*, Bd. v. p. 479). In exactly what form it circulates in the blood is not known; but most probably it is as an alkaline carbolate. Lemaire (*loc. cit.*, p. 77) states that it may be found in the breath of poisoned animals; but Hoffmann asserts that it is burnt up in the system, because he failed to detect it in any of the secretions. In this conclusion he is, however, certainly in error; for it has been distinctly proved that carbolic acid is rapidly eliminated from the system. It has been detected in the urine by Almén (*Zeitschrift f. Analyt. Chemie*, Bd. x. Heft vii.), by Patrouillard (*Journal de Pharmacie et de Chimie*, Dec. 1871, p. 459), by Salkowski (*Pflüger's Archiv*, Bd. v.), by Hoppe-Seyler (*loc. cit.*), by Waldenström (*Zeitschr. des Allgemein. Apothek.-Vereines*, Jan. 10, 1872), and by Hauxmann (*Ibid.*); and Hoppe-Seyler (*loc. cit.*, p. 480) has detected it in the saliva. It is probably eliminated in all the secretions. The researches of Baumann (*Zeitschr. f. Physiol. Chem.* 1878, 350), which have been substantially confirmed, show that the carbolic acid is changed into a peculiar sulphocarbollic acid, a sort of ether-sulph-acid, having the formula $C_6H_5O \cdot SO_3OH$, which finally unites with potash and is eliminated as a sulphocarbo-

late; when large quantities of the acid are administered, some of it escapes unchanged, for in a fatal case of poisoning Patrouillard (*Zeitschr. des Allgemein. Apothek.-Vereines*, p. 460) obtained an oily fluid, believed to be pure carbolic acid, by shaking the urine with ether, allowing the mixed fluids to separate, and removing the ethereal layer and evaporating.

Although, as stated, carbolic acid is to some extent eliminated from the system, a portion of it is burnt up in the body. The black coloring-matter of the characteristic urine of carbolic acid poisoning is in all probability an *educt from carbolic acid*, formed by its partial oxidation. Hauxmann has proved that it is not altered hæmatin or any fixed coloring principle, by finding that the urine is cleared up by heating after the addition of an acid; and his conclusion is corroborated by the observation of Dr. Stevenson, of Guy's Hospital (*Brit. Med. Journ.*, April, 1870), who found that the black urine does not contain more than a normal proportion of iron. When carbolic acid is oxidized outside of the body, as by the action of permanganate of potassium, oxalic acid is formed; and Salkowski has found that when phenic acid is given to animals oxalic acid appears in the urine. Other observers have, however, failed to find these oxalates. Fr. Schaffer (*Journ. f. Prakt. Chem.*, xviii. 282), A. Uerbach (*Virchow's Archiv*, lxxvii. 226), and E. Baumann and C. Preusse (*Zeitschr. f. Physiol. Chem.*, iii. 156) found that the phenol was at least in part oxidized into *hydrochinon*, and partly into a greenish-black substance upon which the coloring of the urine seems to depend. The researches of L. Brieger (*Zeitschr. f. Klin. Med.*, 1881, ii. 25) led him to the conclusion that when carbolic acid is taken in not too large quantities a portion of it unites with sulphuric acid, and a portion of it is converted into various colored oxidation products, some of which are very poisonous. According to the experiments of W. Kochs, this change occurs in the large abdominal glandular viscera (*Arch. f. Physiol.*, xx. 64, xxiii.). Schmiedeberg has recently come to the conclusion that no phenol is oxidized in the body, but that it is all eliminated in combination with sulphuric acid, or to a less extent with glyco-uronic acid (*Arch. f. Exper. Path. u. Therap.*, xiv. 288). The evidence is, however, too strong against this view, and the true conclusion seems to be that when carbolic acid is taken in *great excess* it is in part eliminated as carbolic acid, and that the remainder of it (the whole of it when taken in moderate amount) is in part escapes in combination with an alkali as *sulpho-carbolic* and *glyco-uronic acids* and is in part oxidized in the system. (See also page 663.) Reule affirms that when the sulphuric acid has all been appropriated phosphoric acid is attacked by the phenol and a phospho-carbolate formed (*Munch. Med. Wochens.*, 1890).

Städeler (*Ann. d. Chem. und Pharm.*, Bd. lxxvii. p. 17) discovered that when sulphuric acid was freely added to cow's urine the latter yielded upon distillation carbolic acid, and concluded therefrom that

normal urine contains carbolic acid. He has been corroborated by Buliginsky (*Hoppe-Seyler's Med.-Chem. Untersuch.*, p. 234) and by Hoppe-Seyler (*Pflüger's Archiv*, 1872, Bd. v. p. 470), and phenol is certainly a constituent not only of the urine of cattle, but also of that of men, dogs, horses, and probably other animals. Baumann has succeeded in producing carbolic acid out of fibrin by a protracted digestion with the pancreatic glandular substance, and Nencki and Brieger have found that it is constantly present in normal human feces. It is probable, as asserted by Salkowski, that the acid is formed in the organism as a late product of the pancreatic digestion. Its elimination by the urine is enormously increased in ileus (one-hundredfold, Salkowski), and diminished in anæmia, phthisis, scorbutus, scrofula, and cancer (Brieger, *Med. Centralbl.*, 1878, p. 545). Hoppe-Seyler's theory that the acid does not pre-exist in the urine, but is formed out of indican during the processes employed for procuring it, is not tenable. It appears to be formed from the albuminous substances, tyrosin being an intermediate product, since Brieger has found that the taking of large doses of tyrosin is followed not by elimination of tyrosin, but by a great increase of the urinary phenol. It is quite possible that the phenol is formed in the intestine by fermentative changes, as Baumann has noticed the closely-allied substance indol produced by the putrefactive changes in a mixture of albuminous substance with a small quantity of pancreas and a little carbonate of ammonium. (See *Pflüger's Archiv*, xii. 862.) In this connection it is interesting to note that Christiani has not been able to find phenol in the urine of chickens fed upon vegetable diet, although a notable amount is present when a flesh diet is allowed (*Zeitschr. f. Physiol. Chem.*, ii.). In a series of experiments Dr. I. Munk obtained three grammes as the average excretion of twenty-four hours from a horse (*Arch. f. Thierheilkunde*, viii. 104).

Local Action.—The local action of carbolic acid is very decided. Applied to the skin, it produces at once a burning pain, and in a few minutes a peculiar white spot. If the acid be removed, the pain continues for some minutes, and the white color changes to a dark or red stain, which gradually fades away as the skin desquamates. On a prolonged application, carbolic acid does not blister, but causes the formation of an eschar. A curious local action of carbolic acid, to which attention was drawn almost simultaneously by Dr. Erasmus Wilson (*Journal of Cutaneous Medicine*, June, 1870) and by Dr. J. H. Bill, U.S.A. (*American Journal of the Medical Sciences*, Oct. 1870), is due to the property which it has when applied in concentrated form of causing very great local anæsthesia. The complete loss of feeling is not confined to the tissue killed by the drug, but extends some little distance inwards.

THERAPEUTICS.—In the doses in which it is usually given, carbolic acid exerts no perceptible effect upon the system. It has been used to a considerable extent in zymotic diseases for the purpose of destroying

the poison in the blood. Even, however, if such poison be micrococci or bacteria there is no reason for believing that these are more sensitive to the action of the drug than is the human organism; and clinical experience with the acid in these diseases has certainly demonstrated its uselessness. The study of its physiological action has failed to show the possession of any property which should render the medicine valuable in constitutional diseases. Our physiological knowledge conforms with clinical experience in showing that carbolic acid is of no value in constitutional diseases, and it is employed directly in medicine only for its local effects.

Internally, carbolic acid is a very valuable remedy in the treatment of various forms of nervous irritability of the gastro-intestinal mucous membranes, especially when there is also a tendency to fermentative changes in the food, as the result of imperfect digestion. In *nervous vomiting*, and in *gastrodynia*, it may be given in doses of from one to two grains, repeated at intervals varying from fifteen minutes to two hours, according to the symptoms of the case. In *diarrhœa of irritation*, as well as of *relaxation*, it is often of the greatest service. The combination of one or two grains of carbolic acid with ten to twenty grains of bismuth, given in emulsion or in capsules, is one of the most generally useful of diarrhœa mixtures.* In *gangrene of the lungs* the internal administration of carbolic acid combined with the use of a weak solution, ten drops to the ounce, by atomization, is said to be of great use. The use of carbolic acid as an antipyretic, as inaugurated by Professor H. M. Desplats (*Gaz. Hebdomadaire*, xvii., 1880), has not found favor, and is scarcely justifiable.

The external use of carbolic acid belongs to the domain of surgery rather than of medicine, and I shall discuss it very briefly. As a *caustic*, carbolic acid is not available when large masses of tissue are to be destroyed, but it may often be employed with advantage against *condylomata* and similar growths. Even in such cases, to be efficient, it must be in the most concentrated form. In *diphtheria*, *ulcerated sore throat*, and *aphthous stomatitis*, its concentrated solution in glycerin may be carefully applied, by means of a camel's-hair brush or a mop, as a mild caustic scarcely capable of destroying sound tissue. In various forms of *indolent ulcer*, in *ill-conditioned wounds*, carbolic acid affords a very useful stimulant application; in "*burns*," properly diluted with oil (gtt. x to fʒi), it is one of the very best remedies that can be used, relieving pain by its anæsthetic properties and at the same time lessening suppuration and facilitating cicatrization.

Dr. Bill (*loc. cit.*) has employed carbolic acid as a local anæsthetic, in a number of cases of minor operations, always with the result of pre-

* In dispensing this, if capsules be used, the two ingredients should be thoroughly mixed before putting in; if an emulsion be employed, the bottle should be stood on its cork or laid upon its side, to prevent permanent separation of the bismuth.

venting or greatly mitigating pain. His plan in opening a *felon* is to soak the fingers for fifteen minutes in warm water containing three per cent. of the acid, and then to draw a brush dipped in the concentrated acid along the line of the incision. Sometimes, when a deep incision is necessary, a sensitive part is reached. Under these circumstances he is accustomed to brush out the wound anew with the anæsthetic.

So far as I know, the first to suggest and employ *deep injections* of carbolic acid as a means of combating *deep-seated inflammations* was Dr. J. A. Eames (*Brit. Med. Journ.*, May, 1873); but the method has been especially studied by Professor C. Hueter (*Deutsch. Zeitschr. f. Chir.*, iv. 1874; *Schmidt's Jahrbücher*, Bd. clxiv. p. 141). He employs a two-per-cent. solution, a weaker one not being efficient, and a stronger one endangering the coagulation of the blood and of the exudation in the inflamed tissue. Of this solution he uses at one time never more than half a drachm, and generally less than this. After anæsthetizing the skin by the local application of carbolic acid, he introduces the hollow needle into the centre of the inflammation obliquely, so as to diminish as far as possible the chances of the introduction of air. To avoid the danger of throwing the acid directly into the circulation, the needle is not connected with the syringe until it is seen that no blood comes out through it. If the extent of inflamed tissue be large, several injections are practised at one time: in acute cases they are usually repeated twice a day, in chronic cases every day, or every other day. Dr. Hueter has made about a thousand of these "parenchymatous injections," and only ten times has any inflammation been excited by them. The pain is usually very slight, and the relief apparent in one or two days at most. In *chronic synovitis*, the drug is thrown into the joint once in two or three days, and the method has been practised by Dr. Hueter with asserted extraordinary success in *glandular swellings* and *inflammations*, *phlegmons* of all grades and characters, *erysipelas*, *poisoned wounds*, *inflamed bursæ*, *hydrocele*, and even in *bone-disease*.

The practice has been followed with satisfaction by Dr. Aufrecht in *erysipelas* (*Centralbl. f. Med. Wissen.*, 1874, p. 129), by Senator (*Berlin. Klin. Wochenschr.*, 1876, p. 69), Mader (*Centralbl. f. Chir.*, 1877, p. 376), and Kunze in acute and subacute *rheumatism* (*Centralbl. f. Med. Wissen.*, 1874, p. 479), by Hagen in several diverse inflammations (*Schmidt's Jahrb.*, Bd. clxiv. p. 146), and by I. Schmidt in *chronic synovitis* (*Centralbl. f. Chir.*, 1876, p. 552). Dr. Hagen has even used these injections with very excellent results in three cases of severe *angina* which he believed threatened diphtheria, throwing the remedy into the neighborhood of the second tracheal cartilage. Dr. Moses K. Taylor (*Amer. Journ. Med. Sci.*, April, 1882) has used injections in one hundred and fifty cases of *buboes* and otherwise enlarged glands, with uniform success. He throws into the inflamed part about twenty minims of an eight-grain solution of the acid, previously chilling the surface with

an ether spray. The total evidence seems to show that this method of treatment is both safe and effective.

Toxicology.—The number of fatal cases of carbolic acid poisoning now on record is quite large, and the list is constantly growing.* The symptoms, although varying within certain limits, are, on the whole, quite uniform. They almost always appear in a very short time after the ingestion of the poison. Sometimes the rapidity of the fatal result almost equals that of prussic acid poisoning. Thus, Dr. Taylor, U.S.N. (*Phila. Med. Times*, vol. ii. p. 284) records a case in which about an ounce is supposed to have been ingested, and in which the man fell unconscious within ten seconds after taking the fatal draught, two minutes afterwards was totally unconscious, pulseless, with irregular distant gasping respirations, and in less than a minute later was dead, apparently from cardiac paralysis, since the impulse of the heart was entirely lost before the cessation of respiration. Generally some minutes elapse before the symptoms develop themselves: nausea, cold sweats,† and stupor deepening rapidly into insensibility and collapse, are the most frequent phenomena. During the period of insensibility, complete abolition of reflex movements and anæsthesia of the mucous membranes have sometimes been noted (case, *Journ. de Pharm. et de Chim.*, Dec. 1871): indeed, it is scarcely doubtful that in all cases both sensibility and reflex movements are profoundly affected. Convulsions are only exceptionally present. The symptoms of collapse are usually well developed, and the pulse is generally feeble and very frequent, but has been recorded as being reduced to from forty to fifty per minute (case, *Med. Times and Gaz.*, April, 1871). Hæmoglobinuria has been noted. Dyspnœa is often extreme; the respirations may be stertorous, are usually very rapid, and, in the advanced stages, shallow. In very rapid cases they are irregular and suspended at intervals. Total temporary amaurosis, with contraction of the pupil, has been noted (case, *Berlin. Klin. Wochenschr.*, xix. 748). Death may occur in a very few minutes; but usually the patient lives from one to ten hours, and life has been protracted for sixty hours (case, *Sydenham Soc. Year-Book*, p. 446, 1871-72; amount taken, one and a half ounces of the commercial acid). In some cases a great amendment has occurred and consciousness been restored, but after some hours rather sudden fatal collapse has come on (case, *Brit. Med. Journ.*, Feb. 1861). The minimum fatal dose of carbolic acid is not known; but half an ounce has several times caused death (*Med. Times and Gazette*, 1870, ii. 474; *Phila. Med. and Surg. Rep.*, Jan. 1870; *Lancet*, 1878, ii. 510), and a little over a drachm is reported to have killed a man sixty-four years old (*London Lancet*,

* References to one hundred and sixty-nine cases of carbolic acid poisoning have been collected by H. Robert (*Schmidt's Jahrb.*, xciv. 229).

† The excessive sweating sometimes seen in carbolic acid poisoning Th. Gins believes to be of central origin, since in a poisoned cat with one sciatic nerve cut, no sweat came from the injured part.

1869, i.); in a case of puerperal metro-peritonitis fifty drops contributed towards the fatal result (Dr. A. D. L. Napier, *Trans. Med.-Chir. Soc. Edinb.*, ii. 75).

The free external use of carbolic acid is by no means devoid of danger: Dr. Falekson, after two hours' exposure to carbolic acid spray, recovered from his urine thirty grains of carbolic acid (*Arch. f. Klin. Chirurg.*, xxvi. 204), and he describes a marasmus or chronic poisoning resulting from the surgical use of the remedy. The symptoms are said to be headache, loss of appetite, bronchial irritation, which finally may become very severe, severe pains in the region of the kidney, recurring vomiting, pruritus, or various paræsthesiæ, and loss of power in the legs. (See also paper by Dr. Wallace, *Brit. Med. Journ.*, April, 1870.)

There have been numerous cases of acute poisoning from the external use of carbolic acid. A single vaginal injection has produced very severe constitutional results (*Schmidt's Jahrb.*, Bd. cci. p. 129). Professor R. Köhler reports (*Ibid.*, Bd. clv. p. 276) the cases of two journeymen joiners, suffering from scabies, who applied externally each about a half-ounce of carbolic acid, in watery solution. One of them was found dead. His fellow, who suffered from unconsciousness and drunken delirium ending in unquiet sleep, after his recovery stated that directly after rubbing himself with the solution he had giddiness, that seven or eight minutes later his companion complained of burning, but that of what took place after this he knew nothing.* It is scarcely necessary to refer in detail to cases in which serious results have followed the surgical use of carbolic acid.† In the *London Medical Record*, Oct. 15, 1887, is recorded a very severe case of poisoning in an infant produced by the use of carbolized cotton wool. The local application of carbolic acid has in a number of instances been followed by a severe local gangrene. For cases see *Med. Times and Gazette*, vol. ii., 1870; *L'Abeille Méd.*, 1871; *Med. News*, vol. i., 1890; and *Bull. Soc. Méd. d. Hôp. d. Paris*, vol. vi., 1889. Dr. A. Frankenburger (*Inaug. Dissert.*, Erlangen, 1891), in an experimental study, found the gangrene to be the result of thrombosis.

The diagnosis of carbolic acid poisoning‡ during life ought in most cases to be practicable; for, although the symptoms simulate some forms of apoplexy too closely for the diagnosis to be made from them, very generally the odor of the drug can be perceived about the person of the victim, and close examination of the mouth will nearly always re-

* For other fatal cases, consult *Bull. Thérap.*, t. lxxv. p. 285.

† Consult *British Medical Journal*, March 1, 1873,—death from absorption by a wound four inches long; *New York Medical Gazette*, April, 1871; *British Medical Journal*, 1865, p. 220,—two fatal cases; *Med. Times and Gaz.*, 1878, ii. 461; *Wiener Med. Wochenschrift*, 1879, xxix. 1233.

‡ Since writing the article on *Carbolated Camphor*, on page 122, I have seen the researches of Combemale and Frangois (*Montpellier Méd.*, 1890), in which it is shown that when injected in the lower animals it acts as a powerful poison, producing vomiting, fall of temperature, bloody urine, epileptiform convulsions, and death.

veal traces of the local action of the acid, in the form of *white, hardened, or corrugated* patches of mucous membrane. Either these, or a *blackish urine* in conjunction with the symptoms, are diagnostic. After death a strong odor of carbolic acid can almost always be perceived when the body is opened, and the mucous membrane of the stomach affords very reliable evidence as to the cause of death. According to Dr. A. Miller, the urine of carbolic acid poisoning as first passed varies from a clear yellow to a golden yellow, and upon standing in the air becomes dark olive and finally often blackish green. Sometimes it is grass-green, but it may appear to be normal (case, *Schmidt's Jahrb.*, Bd. cii., p. 238). This carbolic acid urine, if treated with nitric acid and afterwards with potassa, becomes, after a certain degree of concentration, blood-red or brown-red, changing through pea-green to violet. Carbolic acid mixed with urine does not answer this test (*Schmidt's Jahrbücher*, Bd. clxiv. p. 144).* The absence of carbolic acid urine proves that the case is not one of poisoning. Baumann and Hueter declare that the earliest symptom of the poisoning is disappearance of the sulphates from the urine (*Zeitschr. f. Physiol. Chem.*, i.).†

In a case of carbolic acid poisoning emetics are generally useless, owing to the paralysis of the stomach which exists, and the stomach-pump must be employed to empty the viscera. Alkalies in excess are of some value, according to Huseinann, who employs a saccharate of lime,‡ and the free ingestion of oils was formerly recommended; but to Baumann and Hueter (*Med. Times and Gaz.*, ii., 1878) belongs the credit of discovering the proper antidote to carbolic acid. They found that during carbolic acid poisoning the sulphates disappear from the urine, and that if a soluble sulphate be given freely to an animal poisoned with carbolic acid, the latter will be converted into a harmless sulpho-carbolic acid.§ Sonnenburg discovered that in patients presenting the dark-colored urine and other symptoms of poisoning resulting from the too free external use of the acid all trouble disappears upon the administration of the sulphate of sodium; and Dr. D. Cerna (*Phila. Med. Times*, ix. 593) has, in an elaborate series of experiments upon animals, employed the sulphate of magnosium with entire success: so that it may be considered established that a *soluble sulphate* is the proper antidote

* For method of detecting carbolic acid in urine, see *Lond. Med. Rec.*, 1877, p. 455.

† To detect the diminution of sulphates in the urine, remove any albumen present by boiling, acidify with acetic acid, and add chloride of barium in excess. This reagent gives a milky cloud of sulphate of barium in the presence of sulphates, but a mere haze or no alteration in carbolic acid poisoning.

‡ Dissolve sixteen parts of sugar in forty parts of distilled water, and add five parts of caustic lime; digest for three days, stirring from time to time, filter, and evaporate to dryness. The product thus obtained dissolves easily in water.

§ For a study of sulpho-carbolic acid, see *La Tribune Méd.*, July, 1884, 328. M. P. Viglier affirms that, while not poisonous to the higher animals, it is an active antiferment. M. Rabuteau (*Compt. Rend. Soc. Biol.*, 1882, iii. 42) finds that the acid is simply a feeble purgative.

to carbolic acid, and that it should be employed very freely and in all stages of the toxæmia, as being capable of neutralizing the poison in the blood. The chemical history of phenol inside of the body explains why the sulphates are so efficient. Dr. De la Bate (*Bull. Gén. de Thérap.*, cv. 418) affirms that he obtained very happy results in one case of carbolic acid poisoning from inhalations of oxygen. Dr. Jos. Szydlowsky saved a pulseless and apparently dying child ten hours after the ingestion of the carbolic acid, by hypodermic injections of ether and the administration of dilute sulphuric acid and sulphate of sodium (*St. Peterab. Med. Wochenschr.*, 1883, x. 87). So long, therefore, as a patient can swallow, the antidote of carbolic acid should be given.

Carbolic Acid as an Antiseptic and Germicide.—In 1870, Grace Calvert proved that albumen was preserved for eleven days when mixed with carbolic acid, and Dr. John Dougall that one twenty-five-hundredth part would destroy spermatozoa and the higher infusoria. Schrooter, in 1878, found that 0.0501 per cent. (one in two thousand) would keep flesh for four weeks, and 0.2 per cent. permanently. It was soon found that the acid acted even more powerfully upon moulds than upon putrefactive organisms.

The first to study the action of carbolic acid upon vaccine lymph were Bruidwood and Vucher, and their experiments have been repeated and extended by Dougall, by J. W. Miller, by Hoppe-Seyler, and by Baxter. Each of the last two observers found that two per cent. of the carbolic acid destroyed with certainty the infective power of vaccine, a conclusion, on the whole, not discordant with that of the other observers.

The germicidal power of the drug has also been studied by Huggo, Rosenbach, Baxter, Sternberg, Davaine, Koch and Blyth, Arloing, Cornavin, Thomas, and various other observers, upon almost all the known forms of infective organisms.

Their concordant testimony shows that one per cent. in an aqueous solution will destroy with certainty the virulence of ordinary septic and purulent matters, of the tubercle-bacillus, and of the micrococci of fowl-cholera; some of the organisms related to putrefaction have also been destroyed by solutions of this strength: but to produce these results with certainty the contact with the disinfectant had to be continued for many hours. Two per cent. of the acid in an aqueous solution was required to destroy the infection of vaccine or of glanders.

There are, it is true, some experiments which seem to be discordant with these results, especially those of Notter and of Jalan de la Croix, who found that as much as ten to thirty per cent. of the acid was necessary to prevent the movements of bacteria in putrid infusions of beef; but there was probably some error in their experimental methods.

As a vapor, carbolic acid seems to act very feebly as a disinfectant or germicide, and it is very evident that the popular estimate of the value of carbolic acid is too high.

CREOSOTUM. U.S.—CREOSOTE—CREASOTE.

This substance is defined by the U.S. Pharmacopœia to be a mixture of phenols, chiefly guaiacol and creosol, obtained during the distillation of wood-tar, preferably of that derived from the beech (*Fagus sylvatica*, Linne). The creosote of commerce is a colorless, oleaginous liquid, often brownish or reddish, having a caustic taste and a penetrating, disagreeable odor, which whilst resembling that of carbolic acid markedly differs from it in being more smoky. It is neither acid nor alkaline in reaction, and forms in water two solutions, having respectively the strength of one to ten and one to eighty. As it occurs in commerce it varies in constitution; and, indeed, even creosote conforming to the official tests varies in the proportion of its ingredients. It consists chiefly of guaiacol and creosol, though certainly other phenoloid bodies occur in it. It is stated that the beech-wood creosote varies in the amount of guaiacol from sixty to ninety per cent. It has been much confused with carbolic acid, and for many years most of the creosote of the drug-stores was an impure carbolic acid. For the tests distinguishing creosote from carbolic acid the reader is referred to the United States Dispensatory.

PHYSIOLOGICAL ACTION.—The physiological effects of creosote have never been carefully and thoroughly studied. It certainly rivals carbolic acid in its antiseptic power. It is, when applied locally, a paralyzant to the nerves, and probably to all higher tissues; indeed, it has been generally believed to be almost identical in the range and powers of its activity with carbolic acid. It differs, however, greatly from carbolic acid in its toxicity, as well as in the range of its usefulness in disease. Thus, Dr. Freudenthal (*New York Med. Rec.*, April, 1892) reports the case of a woman who took six hundred drops of creosote in a very short time, the ingestion being followed almost immediately by unconsciousness, with intense trismus, contracted immobile pupils, and general cyanosis, but in which recovery occurred without the administration of remedies. He further states that subsequently this same patient, by increasing the dose of creosote, was able to take five hundred drops daily without ill effect. Besides this, Müller (*Wurtemb. Correspondenz-Blatt*, 1869), T. Stevenson (*Guy's Hosp. Rep.*, 1875, xx. 144), Pürekhauser (*Friedrich's Blätter f. Gericht. Med.*, 1883, 430), F. Grinell (*Med. News*, xl. 345), and Manouvriez (*Soc. Méd. Légale de France*, vii. 198) have each recorded a case of creosote-poisoning. The symptoms have been similar to those of carbolic acid poisoning,—namely, burning in the gullet and stomach, vertigo, faintness, unconsciousness, collapse, blackish urine, stertorous breathing, and great cardiac depression.

The absorption and elimination of creosote are very rapid. M. Salliet (*Bull. Gén. Thérap.*, cxxiii.), within the nine hours following the administration of eight centigrammes, obtained from the urine forty-eight milligrammes; after sixteen centigrammes, one hundred

and eleven milligrammes; and it would appear that about two-thirds of the dose escapes from the body through the kidneys in the time mentioned. Imbert (*Nouveau Mont. Med.*, i., 1892) recovered one gramme of guaiacol from the urine after the hypodermic injection of two grammes; after two grammes of a mixture of guaiacol and creosol, sixty centigrammes; and so on; so that it would appear that a portion of the creosote is destroyed in the body. This conclusion is, however, rendered doubtful by the fact that the creosote escapes through other channels than the kidneys. It has been found abundant in the sputa of phthisical patients, and, indeed, M. Catillon (*Bull. Mem. Soc. Therap.*, 1892) affirms that it is chiefly thrown off through the lungs. It occurs in the urine probably in the form of oxidized educts, but chiefly as creosol and guaiacol sulphates; so that, as has been practically proved by Professor Hubart A. Hare (*University Med. Mag.*, vol. i.), sulphuric acid and the soluble sulphates are antidotal to it.*

THERAPEUTICS.—Creosote has been used in medicine, first, as a germicide; second, for its local effects. On account of its supposed influence on the tubercular bacillus it was introduced in the treatment of *phthisis*. It has received in this disease much commendation, especially from Professor Sommerbrodt, who has recently reported thirteen years' experience with it. He insists on the necessity of the purity of the creosote, and of the use of large doses—one to two grammes per day—for many months or years. My own experience is in accord with the general drift of the clinical results obtained by authors, in showing that whilst creosote is a valuable remedy in *phthisis*, it is not a specific, and will rarely, if ever, bring about a cure: that it acts in these cases by poisoning the bacilli is very doubtful. Any such action must be purely local,—i.e., due to creosote excreted in the lung,—since Drs. F. Holscher and Rich. Seifert (*Berlin. Klin. Wochens.*, xxix., 1892) found that in young rabbits and dogs, to which guaiacol had been freely given, the serum of the blood was not at any time capable of checking the development of bacilli in agar-agar; so that the conclusion of the experimenters, that guaiacol during absorption becomes converted into an albuminous compound which has no influence upon the lower organisms, is plausible. On the other hand, it seems to be established that creosote is largely eliminated with the sputa; but Bogdonovitch and other clinicians or experimenters have found the bacilli abundant

* Imbert finds that the proportion of creosote eliminated diminishes with the increase of the dose. Thus, after an enema of one gramme, fifty-four to sixty per cent. was found in the urine; after two grammes, forty-eight per cent.; after four grammes, thirty per cent. When four grammes were administered, the expectorations showed its presence for twelve hours. After a subcutaneous injection, Imbert was not able to recover from the excretions more of the creosote than after it had been given by enema. Although there were severe persistent pain and swelling, no suppuration or sloughing ever followed these injections. Imbert also found that the elimination ceased at the end of twelve hours after large as well as small doses (*Bull. Gén. Thérap.*, cxlii., 1892). For methods of finding creosote in urine, see also *Bull. Gén. Thérap.*, May, 1892.

and active in the sputa of phthisical persons taking the remedy. **Brissonet** (*Therap. Gaz.*, 1893) and **Holscher and Seifert** (*Berlin. Klin. Woch.*, 1892) present evidence to show that guaiacol neutralizes in the blood those poisonous products of bacillary growth which are the cause of the fever, sweating, disordered digestion, etc., of the phthisical patient; in other words, that creosote acts chemically in the blood. At present this seems to be not more than an ingenious theory. In my experience, creosote acts most favorably in cases with very free expectoration, and I have seen it do as much good in simple pulmonary catarrh not resting upon a tubercular basis. I believe it, therefore, to be simply a valuable alterative, stimulant expectorant, which also may do good by checking intestinal fermentation and improving the digestion.

On account of its local action as a nerve paralyzant, creosote is frequently employed with great advantage in nausea, vomiting, or diarrhœa dependent upon excessive irritability, without acute inflammation, of the gastric or intestinal mucous membrane; it has thus been successfully used in the vomiting of pregnancy or of hysteria, in cholera morbus, cholera infantum, lienteric diarrhœa, typhoid fever, and even in dysentery. When in these cases there is a tendency to fermentation of the contents of the stomach or bowels, creosote is especially valuable, and may often be combined advantageously with an alkali or chalk. Whether it is in these affections superior to carbolic acid is doubtful.

Externally creosote has been employed for exactly the same purposes as has carbolic acid. The skin-diseases to the treatment of which creosote has been supposed to be best suited are those of a scaly character. In burns its efficacy has been insisted on, especially when there is excessive suppuration or fungous granulations. In chilblains also it is stated to be a useful application. Mixed with four parts of lard, it is said to have proved very serviceable in erysipelas. When applied to wounds it acts as a hæmostatic, stopping the capillary hemorrhage, but it possesses no power to arrest the bleeding from large vessels. Accordingly, creosote water has been applied locally in menorrhagia, and to arrest uterine hemorrhage and the bleeding from leech-bites. Wherever there are foul ulcers, gangrenous surfaces, or inflamed serous, mucous, or glandular tissues giving rise to fetid discharges, creosote may be substituted for carbolic acid; as examples may be mentioned fetid leucorrhœa, puerperal metritis, fetid otorrhœa, putrid or diphtheritic sore throat, chronic empyema, chronic fistula. The strength of the application may vary from that of pure creosote to a single drop to the fluidounce of water, according to the delicacy of the part and the severity of the disease.

Numerous attempts have been made to bring creosote in direct contact with the tuberculous lung. Thus, its solution in oil has been by various practitioners injected directly into the pulmonary parenchyma. (See *Internat. Klin. Rundschau*, Feb. 1890.) Dor's method consisted of injecting into the trachea from five-tenths to two centimetres of the

five per-cent. solution of creosote in olive oil previously boiled. Neither theory nor result seem, however, to justify these violent procedures. The inhalations of the vapor of creosote have been very largely used by means of respirateurs or other mechanical contrivances, and the British Pharmacopœia recognizes *Vapor Creosoti* (twelve minims to eight fluidounces boiling water).

The ordinary dose of creosote is from one to three minims; but much larger quantities have been administered in the treatment of phthisis, some practitioners stating that they have given as much as a drachm by the rectum at one time. Creosote is often given in capsules; in this form it should always be taken upon a full stomach. Large doses of it should always be administered dissolved in a considerable bulk of water and glycerin, or of spirit and water, or of cod-liver or other oils, so as to avoid local irritation. Creosote has also been used hypodermically in phthisis. Thus, Perom employed a ten-per-cent. solution in oil of sweet almonds, two injections of eighty minims each being given daily. This method of administration does not seem, however, to present sufficient advantage to counterbalance the pain and local irritation caused. The dose of creosote water (*Aqua Creosoti*—10 per cent., U.S.) is from half to one fluidrachm.

GUAIACOL.—Creosote depends for its therapeutic value largely upon the guaiacol it contains. As the proportion of this remedy in it varies, it is evident that pure guaiacol itself is preferable to the crude drug. Pure guaiacol is a syrupy liquid, with an agreeable odor, which has been used in medicine pure and in the form of various compounds, especially of the *Guaiacol Carbonate*. This is a white powder, almost odorless and tasteless, insoluble in water, slightly soluble in alcohol, sparingly soluble in glycerin and fixed oils. Dose, five grains (one-half to one drachm daily). Guaiacol itself may be given in capsule, in milk, wine, or oil. Dose, five drops (twenty to forty minims daily). Max Schueller, of Berlin, claims that it is a very valuable local remedy in *lupus* and other forms of *external or surgical tuberculosis*. He at one time also used largely by inhalation an aqueous solution of one part to six hundred. Recently he teaches that the inhalation should not be employed unless there be tubercular catarrh of the respiratory mucous membrane.

I believe Dr. Guinard (*Bull. Thérap.*, Oct. 1893) was the first to suggest the local application of guaiacol as an *antipyretic* in *phthisis*. The results which he attained have led to trial of the drug in other diseases, such as *pneumonia* and *typhoid fever*. The thoroughly cleansed skin of the abdomen or chest is painted by means of a camel's-hair brush with from twenty to fifty minims, and an impermeable dressing applied to prevent evaporation. The temperature is said to fall decidedly, sometimes as much as seven degrees, in the course of an hour or two, without collapse or other evidences of marked general systemic disturbance.

MENTHOL, U.S., or *Oil of Peppermint Camphor*, has lately obtained great notoriety as a local anæsthetic, and, if freely rubbed upon a part, it undoubtedly will often relieve neuralgic pains when they are superficial and peripheral in their origin: its solution (2 to 10 grs.—13i water) is said also to be very effective in *pruritus ani*, *chronic painful eczemas*, *urticaria*, etc. Its physiological action has been studied by Paolo Pellacani (*Arch. f. Exper. Path. u. Pharm.*, xvii. 376). In the frog it causes paralysis, first of the spinal centres and finally of the nerve-trunks. In the mammals both mobility and sensibility are depressed, the animal grows cold, the respiration becomes slow and shallow. Small doses excite, larger paralyze the frog's heart. In the poisoned mammal there were very curious, unexplained rhythms of rise and fall of the blood-pressure. Dr. Goldscheider (*Archiv f. Physiol.*, 1886) has been led to the conclusion that the sensation of cold produced by the local application of menthol is due to a special influence exerted upon the special nerves of temperature by finding—first, that after the application of a solution of menthol in lanolin the local temperature is increased 2° C., although a marked sensation of cold has been produced, and, secondly, that the cold is not due to evaporation, because covering the part to which the menthol is applied with a watch-glass does not affect the sensation. The doctor also found that if the menthol ointment were applied to one side of the forehead, bodies which previously had caused the sensation of cold no longer did so, and that applications of menthol caused the sensation of warmth upon the elbow and the volar side of the wrist, positions at which, according to Professor Herzen, similar warm sensations are caused by pressure upon the nerve-trunks. Dr. S. A. Russell (*Med. Rec.*, Nov. 1885) affirms that menthol has a remarkable power of controlling superficial inflammations. He applies an ethereal solution, of the strength of from 10 to 50 per cent., two or three times a day by means of a camel's-hair pencil, and claims to control thereby *boils*, *carbuncles*, *superficial abscesses*, etc.*

THYMOL. U.S.

Thymol is found in the oil of thyme† and of some other plants. It occurs either as an uncrystallizable liquid or in white rhombic or acicular crystals. It has been used with satisfaction as a substitute for carbolic acid by Volkmann and Ranke, of Halle, and other practitioners, but, although it is undoubtedly powerfully antiseptic, does not seem to

* *Camphor-Menthol*.—When equal quantities of pure menthol and camphor are triturated together a clear liquid is formed. It has been strongly recommended by Dr. S. R. Bishop (*Kansas City Med. Ex.*, 1892) as a local application in *rhinitis* and *laryngitis*, twenty per cent., and full strength in *eczema*.

† According to Cardon and Meunier (*Journ. Med. Vet. Zootech.*, 1890), the physiological actions of the oils of *Thymus serpyllum* and of *Thymus vulgaris* are the same; they produce in animals dilated pupils, staggering gait, hallucinations, loss of sensibility, muscular relaxation, insomnia, trembling, contractures, exceedingly rapid respiration, and death, preceded by complete muscular relaxation and anæsthesia.

have rapidly gained favor. Its fragrant odor has proved a decided disadvantage, in summer at least, by attracting swarms of flies. It is not free from poisonous properties. On the other hand, it is claimed that it does not irritate the skin, and has a decided influence in preventing discharges. Spencer Wells employs its watery solution (1 to 1000 of warm water); Volkmann, thymol 1 part, glycerin 20 parts, alcohol 10 parts, water 1000 parts. It has been used internally by Bälz (*London Med. Record*, 1878) in doses of thirty grains a day, or less. In a few instances nausea and vomiting were caused. There was abundant sweating, ringing in the ears, deafness, constriction in the forehead, reduction of temperature, and frequently diarrhoea. The urine was dark greenish, yellowish brown by transmitted light, free from albumen, becoming cloudy and grayish white on the addition of the tincture of the chloride of iron. Violent delirium occurred several times, also marked collapse, and, in one case of typhoid fever, unconsciousness, with most alarming collapse. Dr. Bälz concludes that the remedy is much less certain and more dangerous as an antipyretic than is salicylic acid. The possession of poisonous properties by thymol has been confirmed by the recent experiments of Dr. B. Küssner (*Med. Times and Gaz.*, Dec. 1878, p. 716). This observer found that when given to dogs and rabbits by the stomach the poison acts very slowly and feebly, on account of its slow absorption, but that when injected into the circulation it produces death by failure of respiration. Coma is developed some time before death, and the blood-pressure, which at first maintains itself, now falls steadily. Post-mortem examination failed to detect fatty degeneration or other lesion in either the solid tissues or the blood. The continuous repeated exhibition of small doses of thymol had no perceptible effect, except to interfere in some way with nutrition, so that the animals lost flesh. According to a statement in *Hoffmann und Schwalbe's Jahresh.*, 1879, 208, Küssner has found that thymol has the power of dissolving the red blood-corpuscles. According to the researches of Dr. F. Blum (*Deutsch. Med. Wochen.*, xvii., 1891), thymol is eliminated through the kidneys partly as thymol itself, partly as thymo-hydrochinon united with sulphuric acid, and partly as a chromogen, which is probably an oxidation product of thymol, and partly as some acid of unknown constitution.

The evidence already forthcoming indicates that the therapeutic use of thymol will be very limited. Its costliness and the absence of marked advantages in its favor militate against its being largely used externally. There is, however, one local employment of it which is important.—namely, as a detergent antiseptic in various ulcerated and diseased conditions of the mouth. For such use its agreeable taste and odor preeminently fit it. That anything is to be gained by its internal administration is not at all certain. Enough has been said to condemn it as an antipyretic. Küssner found the sugar in the urine of a patient with diabetes reduced by from one to two grammes of thymol per diem;

but Fürbringer (*Deutsches Archiv f. Klin. Med.*, xxi.) reports a case in which one gramme daily increased the sugar. Küssner thinks thymol (three to five minims of a one-per-cent. solution three times a day) of value in *vesical catarrh* and in *infantile diarrhœa*, and found that inhalations (1 part to 1000) diminish the fever and expectoration of *phthisical* patients. Dr. Martine commends it as an antiseptic sedative in *typhoid fever*, *intestinal catarrh*, etc., confirmed by Dr. F. P. Henry, in dose of thirty grains in the twenty-four hours (*Med. News*, Sept. 18, 1887); Dr. Gros commends it internally in *diphtheria* (*Deutsch. Med. Wochen.*, 1890).

Thymacetin is a white crystalline powder, very slightly soluble in water, which has the same chemical relation to thymol that phenacetin has to phenol. According to Professor Solly, it is a valuable analgesic in neurotic pains and is also soporific (*Centralb. Gesamte Therapie*, Feb. 1892). Dose, five to fifteen grains, in capsule.

RESORCINUM—RESORCIN.* U.S.

In 1864, Hlasiwetz and Barth produced from galbanum a substance to which the name of resorcin was given, and which is now obtained as a derivative of phenol. It occurs in colorless, short, aromatic prisms or plates of an unpleasantly sweet, somewhat acid taste, which on exposure to the air become reddish. It is freely soluble, at 59° F., in 0.6 part of water, in alcohol, in ether, and in about twenty parts of fixed oil.

PHYSIOLOGICAL ACTION.—Resorcin appears in its physiological properties to be allied to carbolic acid. It is distinctly poisonous to the lower organisms, and, according to Martin Cohn (*Inaug. Diss.*, Berlin, 1882) and Dr. Andoer (*Ueber das Resorcin*, Würzburg, 1880; also *Centralbl. f. Med. Wissens.*, 1881), a one-per-cent. solution of it is sufficient to arrest for a long time putrefactive changes in the urine, organic infusions, and even animal tissues. Platt states (*Amer. Journ. Med. Sci.*, vol. i., 1883), however, that it is distinctly inferior to carbolic acid as an antiseptic. When given to the lower animals (Dujardin Beaumetz, *Bull. Thérap.*, ci. 113) it causes tremors, loss of consciousness, and epileptiform convulsions, which, when the dose has been sufficiently large, become more and more violent, until the increasing disturbance of breathing ends in respiratory arrest. During the spasms the temperature of the animal is distinctly elevated, but when there is quiet narcosis it may fall below normal. The urine becomes olive-green, deepening into blackish.

In doses of twenty to forty grains resorcin causes flushing of the face, with giddiness, buzzing in the ears, and some quickening of the breathing and pulse, followed, after a time, by violent perspiration and

* *Thioresorcin* is a sulphur substitution product from resorcin. A case of poisoning by its external use is reported by Dr. H. Amon (*Minch. Med. Wochens.*, xxvi., 1889). The most peculiar symptom was erythematous oedema of the face, and general eruption somewhat similar to that of measles, with intense itching.

sometimes depression of temperature. Sixty grains caused in man giddiness and violent perspiration, with marked anxiety, ending in collapse and unconsciousness. Andeer took about one hundred and fifty grains of resorcin, dissolved in a pint of water, during fifteen minutes. After disturbance of the cerebration and of the special senses, he fell into a condition of collapse, with cold extremities, epileptiform convulsions with loss of consciousness, opisthotonos, and marked disturbance of the respiration. Consciousness did not return for five hours. Dr Murrell records (*Med. Times and Gaz.*, vol. ii., 1881) a case in which a woman took one hundred and twenty grains of resorcin, and immediately felt giddy, had sensation of pins and needles all over her, and a few minutes later was insensible, with closed eyes, clinched hands, pallid, blanched lips, dry tongue, normal pupils, and insensible conjunctiva; the temperature was 94° ; the reflexes were entirely gone; the pulse was weak and thready. Dr. Jos. Loeffler (*Wurzburg Thesis*, 1889) reports the case of a woman, thirty-one years old, who, immediately after the injection into the stomach of two litres of a three-per-cent. solution of resorcin, was seized with violent gastric pain, followed at once by unconsciousness, cyanotic face, and clonic contractions. In spite of the immediate removal, as far as possible, of the solution, the cyanosis became more intense, the unconsciousness and muscular relaxation complete, with, from time to time, active tremors; the pulse very small and frequent; the respiration completely arrested, with respiratory muscles in such a condition of tetanus as greatly to embarrass artificial respiration. Under the continued use of this artificial respiration, however, recovery was finally secured. In several cases of children, the washing out of the stomach with a three-per-cent. solution has been followed by collapse and death, and in one case hæmoglobin was found in the urine. The chief action of resorcin is upon the nerve-centres, although, like carbolic acid, it probably affects all highly-organized tissues. The experiments of Dr. Beyer (*Amer. Journ. Med. Sci.*, April, 1886) show that it has a direct action upon the heart.—moderate doses paralyzing the sinus and auricles, and very large doses causing immediate diastolic arrest of the whole heart.

Elimination.—According to Dr. Joseph Schomacker (*Thesis*, Dorpat, 1886), resorcin is eliminated with the urine as a sulpho-acid, which on boiling with HCl is decomposed, resorcin being set free; after very large doses, free resorcin may be found in the urine. The excretion is said to be completed in about seven hours.

THERAPEUTICS.—Although resorcin is capable of acting as an antipyretic, it is certainly inferior and more dangerous than other remedies of the class, and has been abandoned as an internal medicament, being employed solely as a topical remedy in diseases of the skin and mucous membranes. Dr. Andeer originally recommended it as an antiseptic stimulant application in uterine and vaginal disease, stating that it must be employed in the form of an ointment spread upon tampons, as the

injection of a two-per-cent. solution is apt to produce severe uterine contractions. It has been strongly recommended by Hoefler, Lichtheim, Janicke, Fliesburg, Baginsky (see *Therap. Gaz.*, vols. ii. and iii.; *Berlin. Klin. Wochens.*, xxvi., 1889), and other physicians, in the treatment of various irritations of the gastro-intestinal mucous membrane, in which it is believed to do good partly by checking fermentative changes in the contents of the alimentary canal and partly by a specific action upon the mucous membrane: in this manner it has been employed in *gastric ulcer*, *vomiting*, and *cholera infantum* and other *diarrhæas*; but in my somewhat limited experience it has not given satisfaction. It has been used also to some extent with alleged good result in inflammations of the upper respiratory passages. Thus, Fliesburg states that in *hay fever* a spray of thirty to fifty per cent. of resorcin, given two or three times a day, is of the greatest service, and that it is possible to arrest *whooping-cough* by the frequent employment of a spray from a five- to twenty-per-cent. solution. Arntzenius and Leblond and Baudier (*Journ. Méd. Paris*, xvi., 1889) also commend the remedy highly in the same disease. The solution of from one to five per cent. has been employed with alleged excellent results as a local application in chronic *otitis*, *gonorrhæa*, *leucorrhæa*, etc. In *cystitis* resorcin may be administered by the mouth, but it is better applied (three-per-cent. solution) by injection. Leblond and Baudier claim extraordinary results in *diphtheria* from painting the diseased pharynx with a ten-per-cent. solution of resorcin and glycerin, and also state that in *whooping-cough* and *pulmonary tuberculosis* great relief is afforded by the inhalation every two hours of the fumes from one gramme of resorcin, heated in a metallic capsule by an alcohol lamp. The three- to five-per-cent. solution has been largely used in Germany in washing out diseased stomachs, but some care is necessary to avoid poisoning. (See preceding paragraph.) It is said to be an active parasiticide, and to be valuable in the treatment of the various skin-diseases dependent upon the presence of an animalcule or of a fungous growth. Too irritating for acute inflammations of the skin, it certainly exerts a powerful effect on recent cell-infiltrations, and is extraordinarily successful in chronic and subacute *eczema*, where there is much thickening from exudation, and even in *psoriasis*: it should be used in solution (grs. x. to f3i), well sopped on, and allowed to dry. According to Audeer, resorcin, in powder or in saturated ethereal solution, is a feeble caustic, useful in the treatment of *chancres*, of *papilloma*, and even of *carcinoma* and *diphtheria*.

Murrell affirms that he has often given forty grains of resorcin at a dose every four hours without the production of any unpleasant symptoms; but this is probably because he had an impure article. Of pure resorcin the dose may be set down as from two to ten grains. For use upon the mucous membrane the strength of the solution may vary from one to twenty per cent. Upon the skin the solution or ointment may vary from five to thirty per cent.

ACIDUM SALICYLICUM—SALICYLIC ACID. U.S.

Salicylic acid has long been known to chemistry, but has only recently been rendered available by Professor H. Kolbe, who discovered that it could be prepared by treating a solution of carbolic acid in caustic soda with carbonic acid at a moderate heat. It occurs in long acicular crystals or in the form of a white, dull powder, of a peculiar pungent odor, and a mild, peculiar taste, accompanied by a transient sense of numbness.

It is soluble, at 59° F., in about four hundred and fifty parts of water and in 24 parts of alcohol. By warming, glycerin can readily be made to dissolve four grains to the drachm; no precipitation occurs on cooling.

PHYSIOLOGICAL ACTION.—When salicylic acid is given to man in doses just sufficient to manifest its presence, symptoms closely resembling cinchonism result. These are fulness of the head, with roaring and buzzing in the ears. After larger doses, to these symptoms are added distress in the head, or positive headache, disturbances of hearing and vision (deafness, amblyopia, partial blindness), and excessive sweating. According to Reiss (*Berliner Klin. Wochenschrift*, 1875, p. 674), decided fall of temperature without alteration of the pulse also occurs; but this is denied by other observers. The action upon the system of the acid and of its sodium salts (also ammonium salt, Martenson, *Petersb. Med. Zeitschrift*, 1875, p. 343) appears to be identical, and, as several cases of poisoning with one or other of these agents have occurred, we are able to trace the toxic manifestations. Along with an intensification of the symptoms already mentioned, there are ptosis, deafness, strabismus, mydriasis, disturbance of respiration, excessive restlessness passing into delirium, slow laboring pulse, olive-green urine, and involuntary evacuations. In some cases the temperature has remained about normal, but in others has approached that of collapse. The respiration appears to be almost characteristic: it is both quickened and deepened. In some cases the dyspnoea has been extreme, and given rise to the most violent respiratory efforts. The suggestion of Dr. Hastroiter (*Med.-Chir. Corresp.-Blatt*, Buffalo, May, 1884) that this dyspnoea is due to pulmonary congestion produced by cardiac weakness is plausible. Sweating usually is very free, and the urine early becomes albuminous. Various local evidences of vaso-motor weakness may supervene, such as rapidly appearing bed-sores at points subjected to pressure, and transitory dark-colored maculæ on various parts of the body.* In several cases death was probably produced by the acid. The most conclusive case is that of H. Quinke (*Berlin. Klin. Wochen-*

* For cases, consult *Deutsches Archiv f. Klin. Med.*, xix, 319; *Centralbl. f. Chirurgie*, 1877, p. 278;—401 grains of salicylate of sodium taken in twelve hours; *London Lancet*, 1876, 2, 681; *Berlin. Klin. Wochenschrift*, No. 4, 8, 1876; and *Bull. Thérap.*, 1877, xviij, 25.

schrift, xix. 710). The chief post-mortem change was a breaking down of the blood, congestion of most of the viscera, and ecchymoses on the serous membranes.*

In rare instances even the therapeutic use of salicylic acid has produced severe skin-eruptions. The form has been sometimes like that of urticaria, in other cases it has been exanthematous or even bullatous. (For references to cases, see Dr. S. Rosenberg, *Deutsch. Med. Wochenschr.*, 1886, 569.)

In some cases of salicylic acid poisoning the mental disturbance has been prolonged for a week or more. It is stated that upon drunkards the acid acts very unfavorably, violent delirium being a common and early symptom of its influence. There are also some persons whose idiosyncrasies are such that mental disturbance is produced even by moderate doses of the acid. In some cases the delirium is cheerful, in others it is melancholic in type. In the mildest form it is manifested only by a tendency to dream actively and to talk during sleep. In other cases the roaring in the ears soon becomes associated with disturbances of vision, which grow more marked until the patient not only sees objects in false appearances and colors but has absolute illusions. The hallucinations are apt to take the shapes of animals such as are seen in delirium tremens, but there is usually little or no terror, and the troops of images may march to beautiful music. In other cases the delirium amounts to acute mania, with restlessness, violent outcries, and even a fury of fighting.† Mydriasis and amblyopia have been noticed in a number of cases; but Drs. Gibson and Felkin report excessive myosis, with loss of the light reflexes (*London Pract.*, xlii., 1889).

When given to dogs by the mouth in large doses, salicylic acid is said to be usually vomited. According to Laborde (*Bull. de Thérap.*, xciii. 276), when from four to five grammes of salicylate of sodium are injected into the veins of the dog the first result is a slight accel-

* In the case recorded in the *Virginia Med. Monthly*, June, 1877, forty-eight grains of the acid were taken in four hours. The symptoms were violent vomiting, headache, total unconsciousness, and stertorous breathing. Death occurred forty hours after the first dose. My belief is that either much more of the acid than forty-eight grains was taken, or, what is more probable, death was from some other cause. See also *Med. and Surg. Reporter*, 1878. There is no probability that in the alleged case of poisoning reported by Dr. Frank Ogston (*Brit. Med. Journ.*, 1883, i. 809) the salicylate had anything to do with the untoward symptoms or result. The case reported by Digneuf (*GAZ. Paris*, 1878), also that of Empis and Gubler (*Bull. de l'Acad. Méd.*, 1877), I have not had opportunity to examine. It is worthy of remark that in the early history of the use of the salicylates disagreeable symptoms appear to have been present much more frequently than of later years, and it is very probable that in many cases such symptoms have been due to the presence of impurities. Thus, *para-cresotic acid* has been isolated from commercial salicylic acid by Professor Dunstan. Both it and the *ortho-cresotic acid* have been found by Professor Charteris to be very fatal poisons to the lower animals, producing general paralysis and death from asphyxia. One grain of *ortho-cresotic acid* and two grains of *para-cresotic acid* caused death in three hours in rabbits weighing two pounds (*Brit. Med. Journ.*, i., 1891).

† For references to cases, see paper by J. Kraeg (*Wien. Med. Presse*, 1886, xxvii. 405).

eration of the heart's action and of breathing; this is followed by efforts at vomiting, quietude, loss of muscular strength, with a decidedly ataxic gait, hebetude, stupor, and finally sleep. When death occurs, it is preceded by dyspnoea and general convulsions. Köhler is probably correct in attributing it to asphyxia. After these general considerations, we can probably best get an idea of the physiological action of the drug by studying its influence upon the various systems in detail.

Circulation.—The action of salicylic acid upon the arterial pressure varies with the dose. The first investigator, Köhler (*Centralbl. f. Med. Wissensch.*, 1876, pp. 163, 195), found that salicylic acid or sodium salicylate injected into the jugular vein causes an immediate fall of blood-pressure, which after a large dose is very pronounced; in a short time the pressure rises to some extent, but not to the normal point, while the pulse-waves become excessively high and two- or three-peaked. As he found that the fall of pressure occurred after section of the depressors, the vagi, and the cervical cord, he very naturally concluded that it was due to an action upon the heart itself.*

In 1879 (*Thèse de Paris*), Hugues Oltremare found that moderate doses of salicylate of sodium increase the arterial pressure and the frequency of the pulse, while poisonous doses strongly depress the heart-force and the blood-pressure. In accord with this are the elaborate experiments of Danewsky (*Arbeiten d. Pharm. Laborat. Moskau*, i. 190). He found that at first the arterial pressure was increased, partly on account of an increase in the force and energy of the cardiac beat, but chiefly as the result of excitation of the vaso-motor centre. Vaso-motor spasm was shown to be the main factor in the rise of the blood-pressure, by the inability of the drug to increase the arterial pressure after section of the spinal cord. The action on the heart was seemingly direct. The arterial pressure slowly fell during the later stages of poisoning, the heart-stroke becoming weaker and weaker, and finally being extinguished. In Paul Faval's experiments upon the isolated heart of the frog small doses of salicylic acid had no perceptible influence, although large doses paralyzed the viscus (*Lyon Thesis*, 357, 1887).

It seems to me established that the fall of arterial pressure observed by Köhler was due to the use of very large doses, and that moderate doses have no depressing effect upon the circulation. This is contrary to the teachings of some clinicians, that the acid should not be used when cardiac weakness exists. E. Maragliano (*Zeitschrift f. Klin. Med.*, 1884,

* Professor Sêo (*Bulletin de l'Académie de Médecine*, 1877, p. 697) states that in his experiments there has been no action whatever upon the arterial pressure or the pulse-rate; but there is reason for believing that these negative results were reached because Professor Sêo gave the acid by the mouth and studied the blood-pressure before the drug was absorbed, since Köhler found (*loc. cit.*) that injections of solutions of the acid into the stomachs of dogs and rabbits failed to affect the blood-pressure, although the sodium salt administered in a similar manner did depress the force of the circulation.

viii. 248), however, in a very large number of sphygmographic and aphygmomanometrical studies, found the arterial pressure usually elevated, and never depressed, by therapeutic doses of the drug. I believe that the general nervous depression which the drug produces when very largely given has been mistaken by clinicians for a cardiac depression; but it must be remembered that when administered continuously the salicylates probably accumulate in the system, and may reach the amount necessary to depress the heart.

Nervous System.—Our knowledge of the action of the drug upon the nervous system is very imperfect. According to Sée, the violent convulsions that precede death are in the lower animals almost the sole evidences of disturbance of the nervous system,—the reflex power of the spinal cord, the general sensibility, and the conducting power of the nerve-trunks not being affected. M. Bochefontaine affirms, however (*Le Progrès Méd.*, 1877, p. 630), that in the frog the drug acts as a paralyzant, destroying the functional power of the spinal centres; while according to M. Laborde four grammes of a salicylate will produce in the dog profound cutaneous anaesthesia (*Ibid.*, 609).

Respiration.—In Köhler's experiments upon rabbits and Danewsky's experiments upon dogs, the respiration during the injection of the acid or its sodium salt into a jugular vein was decidedly quickened, but after a time the rate fell to much below the normal. When, in Köhler's experiments, the pneumogastrics were divided during the period of retardation, the frequency of the respiration was still further lessened. Danewsky practised section of the vagi before exhibiting the drug and during the first stage of accelerated breathing. In the first instance he found that the breathing was only slightly accelerated by the drug; in the second, that the quickened respiration fell to the same slowness that is seen in the unpoisoned animal with cut pneumogastrics. His experiments were too few to be conclusive, but indicate the correctness of his deduction that the quickening of respiration is largely due to an irritation of the pulmonary vagi, and not solely to an influence upon the respiratory centres. There is, however, probably some stimulation of the respiratory centres after small doses; but after very large doses fatal failure of respiration occurs through a gradual or sometimes sudden depression of the centres.

Muscle Action.—According to the experiments of Dr. Charles Lison (*Marseille Méd.*, 1890), salicylic acid has a distinct influence upon the muscle tissue of the frog, producing a primary increase and secondary decrease of excitability and altering the character of the muscular contractions.

Temperature.—Especial interest attaches to the action of salicylic acid upon the temperature. In Professor Sée's experiments upon normal men and upon animals, very large doses (ten grammes for men) had no effect upon the temperature (*loc. cit.*). The experiments of Dr. Paul Fürbringer upon rabbits, dogs, and men are in accord with

this (*Zur Wirkung des Salicylsäures*, Jena, 1875). M. Gedl, in twelve seemingly very carefully conducted experiments upon man, in which the doses varied from forty-six to seventy-eight grains, found that the effect in three cases was various, in two cases negative, in three a lessening of the daily alterations of temperature, in three a slight lowering of temperature, and in one a fall of 0.8° C. (*Centralbl. f. Med. Wissens.*, 1876, p. 403). Danewsky states that in normal animals and man the influence of the acid upon temperature is slight and inconstant. The evidence seems to show that salicylic acid, like quinine, has, in non-toxic doses, little or no decided action upon the temperature in health. In one or two experiments upon himself, Mr. North (*Practitioner*, xxiii. 184) found that the acid exerted a decided influence in preventing the rise of bodily temperature normally caused by exercise.

Dr. Hobart A. Hare has reported (*Therap. Gaz.*, vol. iii. p. 450) a series of experiments made for the purpose of determining the influence of salicylic acid upon the production and dissipation of animal heat. Unfortunately, however, the doses which he employed were not sufficiently large to produce positive results. Especially was this true in the experiments made upon animals suffering from fever. Indeed, there was not in those animals suffering from fever any fall of bodily temperature under the influence of the salicylic acid administered. To attempt to reason from the results reached as to the method of the action of salicylic acid when it does cause fall in bodily temperature seems to me futile.

The first effect of a single antipyretic dose in fever is usually a profuse sweat, which may appear fifteen minutes after the ingestion of the remedy (Ewald, *Practitioner*, xvi. 200). Very shortly after this the temperature begins to fall, and, according to Justi (*Centralbl. f. Chirurgie*, 1876, p. 629), the depression reaches its maximum in about six hours. The sweating is profuse and exhausting, amounting, according to Ewald, not rarely to seven hundred and fifty grammes. The perspiration can scarcely be the only factor in the reduction of temperature, as there appears to be no relation between its amount and the degree of the fall, and it usually ceases before the latter reaches its maximum.

The statements in regard to the action on the pulse in fever vary so much as to suggest that when any decided lessening of the cardiac beat does occur, it is dependent upon the fall of temperature. Thus, Garcin (*Journ. de Thérap.*, 1876, p. 25), Oulmont (*Le Progrès Méd.*, 1877, p. 567), and Moeli (*Deutsches Archiv*, xvii. 592) have all observed the pulse-rate to fall with the fever-heat, while L. Schroeder affirms that after moderate doses the pulse is slackened, after large ones quickened, and Ewald and other observers state that it is usually not affected. The antipyretic dose employed varies somewhat. Ewald gives as a minimum to the adult seventy-five grains, repeated in five hours if necessary; Justi, from ninety to one hundred and twenty-five grains.

Absorption and Elimination.—Salicylic acid appears to be absorbed very rapidly. Drasche (*Centralbl. f. Chir.*, 1876) affirms that almost immediately after the application of its alcoholic solution to the sound skin, the acid may be found in the urine; and in Kumagawa's experiments, salicylic acid was so rapidly absorbed from the intestines that it failed to diminish the indican of the urine by checking fermentation in the intestines. Owing to the insolubility of salicylic acid, the problem of the method of its absorption and of the state in which it circulates in the blood early attracted attention. Salkowski (*Berlin. Klin. Wochens.*, 1875, p. 297) pointed out that the acid in the blood probably exists in the form of a salicylate of sodium. Professor Binz supposes (*Lond. Pract.*, xxvi. 443) that the acid is liberated in the blood by the carbonic acid formed in the tissues. The only basis for this theory consists in the fact that by passing carbonic acid gas through a solution of phosphate, carbonate, and salicylate of sodium, agitating with ether, and separating and evaporating the latter, crystals of salicylic acid are obtained. It is evident that if in the blood changes take place similar to those which occur in this solution, salicylic acid should be yielded to ether shaken with the blood of an animal poisoned with the drug. Feser and Friedeberger found that unless enormous doses of the drug were injected into the blood, so as to produce immediate violent convulsions and death, the vital fluid of the poisoned animal yielded nothing to ether. In Kohler's experiments (*Centralbl. f. Med. Wissens.*, 1876, p. 553), when salicylic acid was dissolved in normal blood no acid was yielded to ether, but when the blood of asphyxia—i.e., blood supersaturated with carbonic acid—was employed, a very notable amount of the acid was extracted by the ether. These experiments seem to me to warrant the conclusion that when the blood is in the normal condition the alkaline salicylates are not decomposed by the carbonic acid in it.

Feser and Friedeberger (*loc. cit.*) have advanced the theory that the salicylic acid circulates in the form of an albuminate. This has received some support from the experiments of Farsky (*Sitzb. d. k. Akad. d. Wissens.*, lxxiv., Bd. ii.), which seem to show that the acid is capable of forming such a compound.* On the other hand, the theory is contradicted by the results of Fleischer (*Med. Centralbl.*, 1876, p. 628), who digested albuminous solutions with the acid, and after coagulation by heat found all the acid in the filtrate, and who also treated the blood of poisoned animals in a similar way, and found the salicylic acid only in the serum, the coagulum being free.

Viewing all this evidence together, it seems a probable conclusion that salicylates, when administered internally, enter the vital fluid and circulate there as salicylates, and that salicylic acid itself is probably

* He digested various albuminous substances with salicylic acid, washed them with ether until it would take no more acid, dried, washed with water, and found on analysis salicylic acid largely present in the residue.

converted by the alkaline juices of the alimentary canal into a salt, and as such enters the system and exerts its influence on the organism.

Salicylic acid escapes from the body chiefly through the kidneys.* Dr. Ugolino Mosso (*Archiv f. Exper. Path.*, xxvi., 1889) recovered, both in man and animals, practically all of the salicylic acid which had been ingested, from the urine, either in the form of salicylic or salicyluric acid. Fürbringer and Drasche (*Centralbl. f. Chir.*, 1876, 777) failed to detect it in the fæces, the saliva, the bronchial secretion, or the sweat, but M. Mussy found it in the saliva (*Bull. Therap.*, xiii. 318), as did also M. Balz; and M. Oulmont detected it in the serosity of a blister. It appears in the urine very soon after its ingestion, but its elimination proceeds slowly. Thus, in a case of exstrophy of the bladder it was detected in the urine dripping from the ureters eight and a half minutes after its ingestion (Balz, *Arch. d. Heilk.*, xviii. 60), and it has been found in the urine eight days after the exhibition of the last dose (Byanow, *Centralbl. f. Chirurg.*, 1877, p. 809). The latter observer also found it in the urine of a normal man as a salicylate twenty-five minutes after its swallowing. The same authority states that it is excreted partly as salicyluric acid,† partly as a form of salicin, and, he believes, to some extent as oxalic acid. Urine which had been passed some hours after the ingestion of a dose polarized to the left. Dr. A. E. Stuart (*Practitioner*, xviii. 425), after so small a dose as nine grains of the acid, saw free, distinct crystals of salicyluric acid in the urine. It is possible that such of the salicylic acid as escapes unchanged from the kidney may, as first excreted, be in the form of a salicylate, but be set free by the phosphoric acid of the urine; at least such would be indicated by the fact that in Balz's case of exstrophy salicylate of sodium appeared in the urine twelve minutes before the free acid. The green color of the urine characteristic of the free use of salicylic acid appears to be due to an increase in the formation of indican (S. Wolfborg, *Deutsches Archiv f. Klin. Med.*, xv. 403; M. Robin, *London Med. Record*, 1877, p. 151), or else to pyrocatechin (see *Bull. Acad. Med.*, 1877, p. 705), and it is not improbable that the pyrocatechin is formed out of the salicylic acid. The urine itself is often augmented in quantity, but sometimes it is diminished. It not rarely contains albumen, evidently the product of a local irritation of the kidneys. Séo reports (*loc. cit.*, p. 705) a case in which the renal irritation was so severe as to give rise to hæmaturia. Although Séo (*loc. cit.*) affirms that in gout the uric acid is greatly increased, and that both in health and in disease the urea is unaffected, the experiments of Dr. Haig (*Med. Clin. Trans.*, London, lxxi., 1888), of S. Wolfsohn (*Centralbl. f. Med. Wissens.*, 1877,

* To detect salicylic acid in the urine, add the solution of chloride of iron carefully. At first white phosphate of iron precipitates, then, if the acid be present, a violet color is produced (Kolbe).

† Salicyluric acid is a parallel compound to hippuric acid, made by the union of the elements of a glyocol with salicylic acid.

p. 30), of C. Virchow (*Zeitschr. f. Physiolog. u. Chemie.*, Bd. vi.), of E. G. Salomé (*Med. Jahrb. Aerzte Wien.*, Bd. iv., 1885), of M. Kumagawa (*Virchow's Archiv*, Bd. cxiii., 1888), and of F. Tausk and B. Vas (*Schmidt's Jahrb.*, Bd. ccxxxvi.), which have been made upon various animals and upon healthy men, are so numerous and so concordant in their relations as to my mind positively to prove that in the normal man or animal salicylic acid and its preparations *increase to a very great extent the elimination of urea and uric acid*. In the experiments of Kumagawa, the uric acid was increased in the healthy dog from thirty to seventy-four per cent. There was also marked increase in the elimination of sulphur compounds, although the relation between the elimination of nitrogen and sulphur, which in the normal animal is fixed, was distinctly disturbed. According to Lecorché and Salamon, in rheumatism there is at first an enormous increase in the excretion of both urea and uric acid, followed by diminution, which may carry the elimination below the norm. In acute rheumatism the first increase lasts three or four days, in subacute rheumatism one or two days; excretion of phosphoric acid is also at first increased and subsequently lessened.

Summary.—In full doses salicylic acid causes symptoms resembling those produced by quinine, but after larger doses there are mydriasis, marked disturbance of respiration, great nervous prostration, delirium, dyspnoea, and, if the dose has been large enough, death by respiratory paralysis. Moderate therapeutic doses appear to have no powerful influence upon the circulation, such physiological evidence as we have indicating that they increase arterial pressure somewhat by exciting the vaso-motor centre and directly increasing the cardiac force. In overdoses salicylic acid causes fall of the arterial pressure, partly by a direct action upon the heart. Our knowledge of the action of the acid upon the nervous system is very imperfect, but it seems to be a depressant of the motor nervous centres. Moderate doses increase the frequency of the respiration, probably in part by an action upon the peripheral pneumogastrics, but chiefly by a direct influence upon the respiratory centres. Toxic doses paralyze the respiratory centres. The action of salicylic acid upon the temperature of normal man is slight and inconstant, unless toxic doses be given; in fever its antipyretic influence is pronounced, but we have no exact knowledge as to the method of its action. It is absorbed and circulates in the blood probably as a salicylate of sodium, and is eliminated partly unchanged as a salicylate, partly as salicyluric acid, the green discoloration of the urine being due to indican, or perhaps to pyrocatechin, which may be an educt from the acid. The elimination both of urea and uric acid is increased by the salicylates, which appear in some way to affect profoundly the general protoplasmic chemical activities. When given in large doses the salicylates irritate the kidneys.

THERAPEUTICS.—The original article of Dr. E. Butt upon the action of salicylic acid upon temperature in fever has been followed by a

number of papers (see *London Med. Record*, 1876, p. 193*), which show that the drug fails in some cases to reduce temperature, but seems to be more certain and decided in its effects than is quinine. The question as to whether good is achieved in fevers by its administration is, of course, entirely separate from that as to its power of reducing temperature. It is certainly possible for a drug to lower the fever heat and yet to do far more harm than good, and the evidence at hand does not yet seem sufficient to answer the present inquiry. In the Semenoff'schen Military Hospital, from January, 1875, to the middle of September, 1875, two hundred and eleven cases of typhoid (?) fever were treated without salicylic acid, and from the last date to March, 1876, one hundred and sixty cases with the acid. The mortality in the first period was 14.7 per cent., in the last 19.4 per cent. (Schroeder, *Deutsches Archiv f. Klin. Med.*, xviii. 516). In the garrison of Stargard, in 1872, thirty-nine cases received mild cold-water treatment; in 1874, sixty-three cases, cold-water treatment energetically; in 1875, thirty-five cases, the salicylic acid treatment; the mortality being, respectively, 30.7, 9.5, and 8.5 per cent., and the average length of treatment 66.6, 53.3, and 37 days (Jahn, *Ibid.*, p. 451). Riess treated two hundred and sixty cases of typhoid fever, and lost 24.2 per cent. (*Berlin. Klin. Wochens.*, xii. 675). He asserts that the duration of the disease was very much shortened. These statistics are all that I have been able to glean upon the subject, and apparently leave the question at issue *sub judice*. The superiority of antipyrin and antifebrin has since their discovery led to the complete abandonment of the use of salicylic acid in fevers.

The antiperiodic action of the drug does not appear to be such as to entitle it to confidence. It is true that Senator in nine cases of *intermittent fever* had but one failure (*Berlin. Klin. Wochens.*, 1875); but the general drift of experience coincides, I think, with that of Helley, who found salicylic acid to fail in obstinate malarial cases, and in mild cases to require longer time to cure than does quinine.

The antipyretic properties of salicylic acid early led to its being used in *rheumatism*,† and in 1876 (*Berlin. Klin. Wochens.*, xiii.) Stricker first announced that it was an exceedingly valuable remedy in this disease, usually, when given in hourly doses of from seven to fifteen grains, causing a disappearance of the symptoms in a period not exceeding forty-eight hours. The conclusions of Stricker have been substantially confirmed by numerous observers in Germany, France, England, and this country. Although some cases of rheumatism do not seem to

* Consult also *Deutsches Archiv f. Klin. Med.*, 1876, xv. 457, 518, 512, xvi. 162, xvii. 294, 314, 607, 692, xviii. 401, 452, 504; *Centralbl. f. Med. Wissensch.*, 1876, xci. 198; *Lancet*, 1877, ii. 812; *Practitioner*, xvi. 200; *Lond. Medical Record*, 1877; *Berlin. Klin. Wochenschr.*, 1875, 693; *Le Progrès Méd.*, 1877; *Bulletin Acad. Méd.*, 1877. For information in regard to its action on pyæmic rabbits, see Fürbringer, *loc. cit.*

† E. Bum was probably the first to make trial of this remedy.

yield to the drug, in the great majority of instances improvement sets in within twenty-four hours, and is rapidly followed by disappearance of the pain and fever. The dangers of cardiac and cerebral complications are certainly lessened, but not altogether done away with.* In excessive *rheumatic hyperpyrexia* it cannot be depended upon to the exclusion of the cold bath. Jaccoud states (*Progrès Méd.*, 1877, pp. 523, 745) that he has found it of great service in *chronic rheumatism*; but the general testimony appears to show that it is less certain in the chronic than in the acute disorder. Jaccoud also states that in acute *gout* it acts with extraordinary effect. As in cases of habitual gout the kidneys are often seriously affected, the urine should always be examined, and if it be found albuminous the remedy should be administered very cautiously. Dr. H. Weber has seen the salicylates act most happily in *gonorrhæal rheumatism* (*Bull. Thérap.*, xciii. 328); but the general experience is that over this disease and over *rheumatoid arthritis* salicylic acid has very little control. Various mishaps (gangrene, *Bull. Thérap.*, xciii. 324; necrosis, *Brit. Med. Journ.*, 1876, pp. 2, 776, 820, 843) have been ascribed to the use of the acid in rheumatism, but these were in all probability accidental complications of the disorder. Delirium and temporary insanity, sometimes erotic, have been in various cases, perhaps correctly, attributed to the acid (*New York Med. Record*, xxi. 456; *London Med. Record*, 1882, 462).

Salicylic acid was at one time highly commended in *diphtheria*, but its use has been generally abandoned, and although in *chronic cystitis* and *chronic pyelitis* it is still sometimes employed, other remedies seem to be of more service. As an alterative diuretic the drug has been commended by Dr. Armin Huber (*Thérap. Gaz.*, 1887) and other clinicians (see *Journ. Méd. de Paris*, August, 1892) in the treatment of *acute* and *chronic pleurisy* with watery effusions.

ADMINISTRATION.—The maximum dose of salicylic acid in acute rheumatism may be set down as a drachm in the twenty-four hours, although it is employed by some practitioners in much larger doses. The *sodium salicylate* (*Sodii Salicylas*, U.S.) contains forty-eight grains of the acid to the drachm: since it is freely soluble in water, and is less unpleasant to the taste and less irritant to the stomach, it is much preferable to the uncombined acid. From sixty to eighty grains of it may be administered in the course of the day in a strongly aromatized syrup. The best method of exhibiting salicylic acid is either in the form of the oil of gaultheria (see p. 685), or in that of the ammonium salicylate. This may be extemporaneously prepared by taking one drachm of salicylic acid and five drachms of syrup and adding aqua ammonia in sufficient quantity to dissolve the acid. The

* Consult for this point Jaccoud (*Le Progrès Méd.*, 1877, p. 688), Green (*London Lancet*, Nov. 11, 1877), Roe (*Lancet*, 1877, ii. 905), Jacobs (*ibid.*, 655), Brown (*Doston Med. and Surg. Journ.*, Feb. 8, 1877).

finished product will be about six drachms, and one teaspoonful will represent ten grains of the acid. If during the use of any preparation of salicylic acid ringing of the ears or other evidences of intoxication appear, the remedy should be at once partly or entirely withdrawn.

Use as an Antiseptic.—Salicylic acid was originally brought to the notice of the profession on account of its inhibitory influence on putrefaction. Kolbe found that 0.04 per cent. had great influence in preventing souring of milk. Bucholz states that 0.15 per cent. is sufficient to prevent the development of bacteria in ordinary organic mixtures, and that the influence of 0.005 per cent. is plainly visible; 0.3 to 0.4 per cent. of the acid killed bacteria in vigorous growth (*Arch. f. Exper. Path. u. Pharm.*, Bd. iv.). The salicylate of sodium was about equal to the pure acid, 0.4 per cent. destroying the bacteria.* In the preservation of urine, Meyer and Kolbe found that one part of salicylic acid to two thousand parts of urine was sufficient to prevent putrefaction (*Journ. f. Prakt. Chem.*, Bd. xii.). According to Kolbe and others, salicylic acid arrests or prevents the action of the non-organized organic ferments. Thus, it will inhibit the action of emulsin upon amygdalin or upon myronic acid, and prevent the development of hydrocyanic acid or of the volatile oil of mustard. Dr. Miller found that one per cent. of salicylic acid was sufficient to check the action of ptyaline upon starch; for the same effect ten per cent. of carbolic acid was required. The digestive action of pepsin, outside of the body, was very seriously affected by 0.2 per cent. of salicylic acid in Dr. Miller's studies, but in Kolbe's experiments the ingestion of twenty grains a day of the drug had no effect.

Salicylic acid has been used to a considerable extent in the preparation of beer and wine, and for the preservation of various articles of food. On the 7th of February, 1881, the French government interdicted this use,† and in 1885 a commission appointed by the Academy of Medicine of Paris, at the suggestion of the Minister of Agriculture, reported (*Bull. Acad. Méd.*, vol. xvi., 1886) that it is proved that the prolonged employment of even very small amounts of salicylic acid is dangerous, and that in susceptible individuals, and especially in aged persons, it is apt to cause disorder of digestion and disease of the kidneys.

There can be no doubt that salicylic acid is capable of accomplishing much in antiseptic surgery, but it does not seem to be replacing carbolic acid, as it at one time bade fair to do. Its freedom from odor and comparative freedom from poisonous and irritant properties are

* The power of the acid has been denied by Fleck (*Benzoesäure*, etc., Munich, 1875), who has been abundantly answered by Professor Kolbe (*Journ. für Prakt. Chem.*, Bd. xii.).

† It is affirmed that in the year 1880 fifty thousand kilos of salicylic acid were used in France for the preservation of foods and wines. Some of the wine was shown to contain three grammes of salicylic acid in every two litres, an amount often drunk in one day by a peasant. (See Chopin, *Hôp. Cochin. Compt.-Rend. Lab. Thév.*, Paris, 1889.)

certainly strong points in its favor: nevertheless, carbolic acid is more generally employed, and Mr. Callender, after twelve months' trial in the wards of St. Bartholomew's Hospital, has formally condemned salicylic acid as much inferior to carbolic acid (*Trans. London Clin. Soc.*, ix.). Thiersch's *salicylic acid wadding* for hermetically sealing wounds is made by dissolving two ounces of the acid in two pints of alcohol (sp. gr. 0.83), diluting with twenty pints of water at 158° to 178° F., saturating with this six pounds and eight ounces of cotton batting deprived of oily matter, and afterwards drying. This wadding contains three per cent. of the acid; for some purposes a stronger batting, containing ten per cent., is prepared. When the wound or abscess is discharging profusely, jute is substituted for the cotton batting, because it is much more permeable to pus. An efficient ointment may be prepared by dissolving one and a half parts of the acid in two parts of alcohol and adding lard, or the solubility of the drug in glycerin may be taken advantage of.

The following solutions are used in St. Bartholomew's Hospital: Phosphate of sodium, three parts; salicylic acid, one part; water, fifty parts.—Salicylic acid, one part; olive oil, forty-nine parts.—Salicylic acid, one part; bicarbonate of sodium, half part; water, one hundred parts.—Salicylic acid, ten parts; borax, eighteen parts; water, one hundred parts. A twenty-five-per-cent. solution, which will bear dilution with water or alcohol, may be prepared according to the following formula: *R* Acid. salicyl., 3ii; *Sodii biborat.*, 3i; *Glycerinæ*, q. s. Mix the acid and the borax with four fluidrachms of glycerin; heat gently until dissolved; then add enough glycerin to make one fluid-ounce. Professor Thiersch has found that the drug cannot be employed for cleaning surgical instruments, because it corrodes the steel.

OLEUM GAULTHERIÆ—OIL OF GAULTHERIA. U.S.

Oil of gaultheria is a very volatile, slightly straw-colored liquid, of a penetrating peculiar odor, ninety per cent. of which is *methyl salicylate*, a substitution-compound in which one atom of the hydrogen of salicylic acid has been replaced by a molecule of methyl, CH_3 . The formula of salicylic acid is $\text{C}_7\text{H}_6\text{O}_3$; of methyl salicylate, $\text{C}_8\text{H}_8\text{O}_3$.

When oil of gaultheria is taken into the animal system, one atom of carbon and two atoms of hydrogen in the methyl are removed by oxidation, and $\text{C}_8\text{H}_8\text{O}_3$ becomes $\text{C}_7\text{H}_6\text{O}_3$. $\text{C}_8\text{H}_8\text{O}_3$ has an atomic weight of 152, while the atomic weight of $\text{C}_7\text{H}_6\text{O}_3$ is 138: so that the administration of one hundred and fifty-two grains of methyl salicylate ought to be equivalent to the giving of one hundred and thirty-eight grains of salicylic acid. As one hundred and sixty-nine grains of oil of gaultheria contain one hundred and fifty-two grains of

methyl salicylate, they should be equivalent to one hundred and thirty-eight grains of salicylic acid.

The oil of gaultheria is practically identical with the *Oil of Sweet Birch* (*Oleum Betulae Volatile*, U.S.), and nearly identical (chemically) with the *Methyl Salicylate* prepared synthetically (*Methyl Salicylas*, U.S.). It is *probable* that these three substances have the same action upon the human economy, but it is not *certain*, and the apothecary should always put up the exact drug called for in a prescription.

The symptoms provoked by oil of gaultheria are similar to those caused by equivalent doses of salicylic acid, excepting that the oil is more irritant locally. An ounce produced violent gastro-intestinal irritation, followed by convulsions, coma, and death in fifteen hours (J. S. Pinkham, *Trans. Mass. Med.-Leg. Soc.*, Boston, 1837). In Juret's case a half-ounce caused death (*N. Y. Med. Gaz.*, 1867); but the same amount has been recovered from (Dr. Gallaher, *Phila. Med. Examiner*, 1852), probably on account of the vomiting induced. Drs. H. C. Wood and Hobart A. Hare have shown (*Therap. Gaz.*, 1886, 73) that the physiological action of gaultheria is the same as that of salicylic acid, and that therapeutic doses are entirely decomposed in the system, although toxic amounts may escape in part unchanged.

Oil of gaultheria affords a very excellent method of giving salicylic acid in cases of subacute and acute *rheumatism*. It may be administered in emulsion or in capsules in doses of from ten to fifteen minims, repeated according to circumstances. I have given as high as one hundred and fifty drops of it in twenty-four hours, though few persons will bear more than half this amount without the production of distinct symptoms, which should be a signal for withdrawal.

SALICINUM—SALICIN. U.S.

Salicin is obtained from the bark of the willow (*Salix*) and other trees. It occurs sometimes in tabular crystals, more frequently in white, shining needles, of neutral reaction, soluble in about thirty parts of cold water, very soluble in hot water and in alkaline solutions. Concentrated sulphuric acid dissolves it, with the production of a beautiful red color. By carefully warming it with dilute sulphuric acid it is converted into glucose and *saligenin*, and it is therefore a glucoside.

The action of salicin upon the animal organism is not known, but would seem to be very feeble, as Ranke (*Pflanzenstoffe*, p. 903) is said to have taken nearly three ounces of it without any notable effect. It is certainly rapidly absorbed, probably as salicin; but once in the blood it seems to be quickly decomposed, the products of its change appearing in the urine fifteen to thirty minutes after the ingestion of a single dose. This change does not appear to be complete, as, according to Husmann (*Pflanzenstoffe*, 963), in the urine of man and rabbits after the ingestion of salicin not only saligenin and salicylic acid occur, but also unchanged salicin. Further, Falck, injecting salicin into the

blood of the dog, found that it chiefly escaped from the kidneys unaltered. The elimination seems to go on slowly, as Senator has detected salicylic acid in the urine sixty hours after the ingestion of a single dose of salicin (*Berlin. Klin. Wochens.*, 1877, 181).

In 1874, Dr. MacLagan, led by some fancied dependence of rheumatism upon malaria, began the use of salicin in acute rheumatism, and in 1876 (*Lancet*, 1876, i. 342) he announced that it was a specific remedy, rapidly abating both the fever and the local symptoms. In the same year (*Centralbl. f. Med. Wissens.*, 1876, 241; also *Berlin. Klin. Wochens.*, 1877, 181) H. Senator confirmed these statements, and further affirmed that in various affections he had found salicin to have an antipyretic power entirely comparable to that of salicylic acid. If these views are correct, the freedom from irritant properties and disagreeable taste make salicin superior to the acid. The only other person who has tested the matter on a considerable scale is Dr. Buss, who does not find that the drug is nearly so powerful as salicylic acid (*Berlin. Klin. Wochens.*, xiii. 504). If, as is believed by Senator, the activity of salicin depends upon its conversion in the blood into salicylic acid, it is plain that its action should be slower and more uncertain than that of the acid.* Further investigations are necessary before a positive conclusion can be reached; but the later evidence does not seem to be favorable to salicin, and it is but little used. In regard to the dose employed, it is worthy of remark that no serious symptoms have been reported as produced by salicin. Senator recommends two to two and a half drachms as a moderate dose for the adult. MacLagan used much smaller doses,—twenty grains every three hours.†

SALOL, U.S., is a white crystalline powder, of a faintly aromatic odor resembling that of oil of wintergreen, almost insoluble in water, and perfectly tasteless. It is a derivative of salicylic acid, one atom of the hydrogen of the acid having been replaced by phenol. It belongs to the aromatic ethers, and may be considered chemically as a salicylate of phenol. Originally prepared by Professor Von Nencki, of Berne, it was introduced into medicine by M. Sahli (*Science Med.*, April 14, 1886). When in the upper part of the intestinal tract it comes in contact with the pancreatic juice it is broken up into its original constituents, salicylic acid and phenol, yielding about thirty-six per cent. of phenol and sixty-four per cent. of salicylic acid.‡ After its free use

* Dr. MacLagan asserts (*London Lancet*, 1872, ii. 179), as proof that salicin does not act as salicylic acid, but as salicin, that he has given salicin to rheumatic patients suffering from cerebral symptoms due to large doses of salicylic acid, and has seen both the rheumatism and the cerebral disturbance abated. Is it possible that the delirium in these cases was due to rheumatic irritation, and not to the salicylates?

† Consult also *Brit. Med. Journ.*, 1876, ii., and *Boston Med. and Surg. Journ.*, Feb. 1877.

‡ Professor Ewald affirms, as the result of experimental research, that salol is not decomposed in the stomach, but immediately upon its entrance into the intestines, and that the products of decomposition appear almost at once in the urine in the form of salicyluric acid, which yields a red precipitate with chloride of iron. Ewald proposes taking advantage of

the urine becomes black from the products of destruction of carbolic acid, and it is capable of causing the symptoms of poisoning by salicylic acid and by carbolic acid, but is said to be less powerful as a poison than are its ununited ingredients, probably because it is broken up slowly and perhaps escapes in part unchanged. Kumagawa has found that it increases nitrogenous elimination.

The therapeutic properties of salol are those of salicylic acid, and a number of clinicians have reported very favorable results from its use in rheumatism. (See Drs. Bielschowsky, Georgi, Rosenberg, and Feilchenfeld, *Therap. Monatsh.*, 1887; also *Lond. Med. Rec.*, Oct. 15, 1886, June 15, 1887, Jan. 15, 1887; also *Berlin. Klin. Wochens.*, No. 4, 1887, and others.) By the use of salol the ringing in the ears and other ordinary constitutional symptoms produced by salicylic acid can be obtained, and there is no doubt that the drug is capable of performing in rheumatism the rôle of salicylic acid. The claim that it is incapable of producing untoward symptoms and that it agrees better with the stomach than do other salicylic preparations is doubtfully sustained. It is, however, less disagreeable to take than some other forms of the acid, but in my experience has been less prompt and less certain in its influence. It has been used in diabetes and as an antiseptic in catarrh of the bladder, and especially as an intestinal disinfectant in typhoid fever and in cholera; but in the experiments of Kumagawa (*Virchow's Archiv*, Bd. cxliii., 1888) it was shown that in animals it produced no lessening of the urinary indican or of the intestinal bacteria, showing that it had failed to exert any antiseptic influence in the intestines. The results of Kumagawa are further confirmed by the researches of Lesnik (*Arch. Exper. Path. u. Pharm.*, xxiv., 1888), who found that outside of the body salol is a very feeble germicide, and, indeed, acts at all only as it is decomposed by the bacteria. To some extent it has been employed by surgeons as an antiseptic in the place of iodoform. According to German authorities, the full dose of salol is half a drachm three times a day. This is, however, a very large dose, not more than half of which should be ordinarily given. The large proportion of phenol liberated in the decomposition of salol indicates that big doses of the drug must be dangerous. Probably, however, much of the large dose usually escapes unchanged from the bowel. It is certain that apparently dangerous doses have often been taken with impunity. Death is, however, said to have been caused by fifteen grains (*Lancet*, May, 1891), but this seems incredible. Hesselbach calls attention to the influence that carbolic acid has upon the cortex of the kidneys, and believes that the

this fact in order to determine the rate at which food passes from the stomach. The urine of seven persons in sound health afforded the salicyluric acid reaction in from one-half to three-quarters of an hour after the ingestion of the drug, but in seven cases of gastric dilatation with weakness of the muscular coat of the stomach two to three hours were required. More recent clinical experiments, however, throw great doubt upon the value of the test (see *Berlin. Klin. Wochens.*, xxvi., 1889, p. 975).

long-continued use of even small doses of salol is dangerous when those organs are diseased.

BETHOL of Sahli, or *Naphtholol* of Kobert, is the salicylate of β -naphthol ether, and occurs in small, white, resplendent, almost tasteless crystals, insoluble in water, but soluble in alcohol and in fats, and having a melting-point of 203° F. It has been introduced to the profession by Merck, and studied to some extent by Kobert and B. H. Sahli (*Therap. Monatshefte*, 1887), and by Lesnik (*Arch. Exper. Path. und Pharm.*, xxiv., 1888). It is a compound analogous to salol, but having the base of naphthol instead of phenol, and consequently splitting up under the influence of the intestinal juices into salicylic acid and naphthol. It contains ten per cent. less salicylic acid than does salol, and has the further disadvantage of possessing a much higher melting-point and therefore splitting up less readily into its component parts. Kobert claims for it that it is preferable to salol in *rheumatism*, as producing less disagreeable after-effects, but Sahli believes that it is not so certain in its action. On account of its not yielding phenol, it is less poisonous than salol. Kobert has found that when given internally it is very useful in the treatment of *catarrh of the bladder*, as well as of *gonorrhæal cystitis*.

BENZOINUM—BENZOIN. U.S.

The concrete juice of *Styrax Benzoin*, a large tree, native of Peru. The drug is said to be obtained by incising the tree and allowing the juice to harden as it exudes. The finest specimens of benzoin consist of tears agglutinated together; the poorest, of brown or blackish masses without tears. The fracture is resinous, the surface of the tears smooth and whitish, the odor fragrant, the taste at first very slight, afterwards somewhat acid. The chief constituents of benzoin are resin and benzoic acid; cinnamic acid is also frequently present, and is said to be especially found in the white tears.

Benzoic Acid (*Acidum Benzoicum*, U.S.) is obtained by sublimation of gum benzoin. As thus prepared, it is in white feathery crystals, of a silky lustre and a fragrant vanilla-like odor, due to the presence of a volatile oil, the pure acid being inodorous. The taste is warm, acid, peculiar. Benzoic acid melts at 250° F., and volatilizes without change; is soluble, when pure, in about five hundred parts of water and in two parts of alcohol at 59° F., in fifteen parts of boiling water, and in one part of boiling alcohol; also soluble in the fixed oils and alkaline solutions. It is a feeble acid, but forms neutral salts with the alkalis. Benzoic acid is widely distributed through the vegetable kingdom, constituting the peculiar principle of all true balsams, and is occasionally present in the urine of grass-eating animals. It is a normal constituent of castor, and has been detected by Seligsohn (*Chemische Centralblatt*, 1861) in the suprarenal capsules of an ox. It is used considerably in

Bunge and C. Schmiedeberg have also found that in the dog with renal arteries tied no conversion of benzoic into hippuric acid occurs, but that tying of the ureters does not interfere with the change. They have also succeeded in converting benzoic into hippuric acid by passing blood containing benzoic acid, with or without glycocoll, slowly through the kidneys, removed from the body directly after death. From some of their experiments it would seem that the blood-corpuscles play an important rôle in the process, as when serum freed from blood-corpuscles was used, at most only a trace of hippuric acid was formed. According to Meissner and Shepard, sometimes the benzoic acid is converted into *succinic* instead of hippuric acid in man, and in chickens it is habitually changed into two new products, one of which is nitrogenous. It has not yet been clearly made out where the nitrogen necessary for the formation of the hippuric acid is obtained. In the elaborate experiments of Carl Virchow (*Zeitschr. f. Phys. Chem.*, vi.), benzoate of sodium caused a decided increase of the nitrogenous elimination from the kidneys; but the testimony as to the effect of the ingestion of benzoic acid upon the urea and uric acid of the urine is singularly contradictory. Thus, Ure (*Medico-Chirurg. Trans.*, 1841, xxix. 30), Leroy d'Etiolles (quoted by Stillé), and Debouy (quoted by Stillé) affirm that the uric acid is very much diminished or altogether absent, while Garrod (*Memoirs of the Chem. Soc.*, i., 1842, and *Lancet*, Nov. 1844) and Keller (*Ann. der Chem. und Pharm.*, xliii., 1842) assert that its quantity remains normal. Again, Garrod affirms that the urea is very much diminished in quantity, while Keller and Meissner and Shepard (*loc. cit.*) declare that it is not affected. The only logical conclusion would seem to be that the effect of benzoic acid upon the solids of the urine is not constant, but varies for reasons at present unknown. All authorities appear to agree, however, in asserting that the acidity is increased.*

In April, 1872, Dougall (*Med. Times and Gaz.*, i., 1872) announced that benzoic acid is an active antiseptic. Since that time, numerous experiments have been made by E. Salkowski (*Berlin. Klin. Wochens.*, 1875, 297), Grube (*Centralbl. f. Chirurg.*, 1876, 778), Bucholtz (*Archiv f. Experim. Pathol. und Pharm.*, Bd. iv.), and Fleck (*Benzoessäure*, etc., Munich, 1875), with the unanimous result of ascribing to benzoic acid a first rank in destroying bacteria and preventing putrefaction. In most of these investigations benzoic acid was found to be much more active than salicylic acid. Bucholtz found that 0.02 per cent. of benzoic acid had a very perceptible effect upon the development of bacteria, and 0.1 per cent. inhibited their growth entirely; also that the benzoate of sodium was no less powerful than the pure acid.

* Dr. Garrod, having discovered that the hippurates have the power, when added to blood-serum containing urates, of causing the disappearance of the uric acid, has suggested their use in practical medicine in uric acid diathesis. He gives of the hippurate of sodium ten grains three times a day. It may well be combined with lithium or potassium salts.

In accordance with this is the observation of Kamagawa, that while salicylic acid has little influence as an antiseptic in the alimentary tract, benzoic acid acts powerfully, notably reducing both the indican in the urine and number of the bacteria in the intestines.

Although benzoic acid was at one time much used in the treatment of chronic bronchial catarrh as a stimulant expectorant, it has in the last decade been especially employed as an antizymotic and antipyretic, and in the treatment of urinary disorders. In diphtheria, erysipelas, and allied diseases, German practitioners have given it with asserted good results, and Professor Senator, of Berlin (*Allgem. Wien. Med. Zeitung*, xxiii., 1876, alleges that it is equal in its action in acute rheumatism to salicylic acid, a conclusion, however, which is not in accord with later experience. Professor Senator's daily dose was in most cases about three drachms. Dr. Ure first suggested the employment of benzoic acid in uric acid gravel and calculus, because, as he thought, it diminished the excretion of uric acid; and Dr. Golding Bird* subsequently asserted that his clinical experience had shown the value of benzoic acid in uric acid diathesis. The results of laboratory experiments (see p. 691) are, however, so discordant that careful chemical studies are urgently needed to enable us to decide whether alleged clinical results are due to a direct action of the drug rather than to some indirect influence. In the phosphatic urine of vesical catarrh benzoic acid often acts most happily; by rendering the urine more acid it increases its power of dissolving the phosphates, while at the same time it stimulates the mucous membrane of the bladder, and exerts an antiseptic influence. In the ammoniacal cystitis the drug is of great value. It is also said often to act very happily in acute gonorrhœa (*Phila. Med. Times*, iv.).

Benzoic acid has the property of preventing animal fats from becoming rancid, and is therefore much used as an addition to ointments. Moreover, it exerts a peculiar, often very beneficial, stimulant action upon the skin, and is very useful in such conditions as chapped hands, lips,† or nipples, and even in fissure of the anus.

There would seem to be no doubt that benzoic acid may be substituted for carbolic or salicylic acid in antiseptic surgery. Under the name of *balsamum traumaticum*, a preparation practically the same as the compound tincture of balsam was formerly much used as a vulnerary. The practice has gone out of vogue; but the discoveries concerning antiseptics and the excellent results obtained by Mr. Bryant (*Lancet*, 1876, ii. 747) show that it was well founded. Mr. Bryant simply covers the wound in compound fractures and other severe in-

* *Urinary Deposits*, Philadelphia, 1859, p. 160. Dr. Bird states that he has found the following formula of great service in chronic uric acid gravel: \mathcal{R} Sodii carbonatis, \mathfrak{z} ss; acidi benzoici, gr. xl.; sodii phosphatis, \mathfrak{z} ii; aquæ ferrentis, \mathfrak{ss} iv; solve et addo aquæ cinnamon, \mathfrak{ss} viiss; tincturæ hyocyami, \mathfrak{ss} iv. S.—Two tablespoonfuls three times a day.

† Professor Stillé commends a mixture of one part of the compound tincture of benzoin and four parts of glycerin.

juries with lint thoroughly saturated with the compound tincture of benzoin, and maintains absolute quiet, with non-removal of the dressing, for some days. His results appear to challenge those obtained by the most complicated antiseptic surgery (see also *Lancet*, 1877, i. 671).

ADMINISTRATION.—The dose of benzoic acid is from ten to thirty grains. Gum benzoin is never used itself, but is exhibited in the form of the *tincture* (*Tinctura Benzoini*—20 per cent., U.S.),—dose, ℥ss to ℥ʒi; and of the *compound tincture* (*Tinctura Benzoini Composita*—12 per cent., U.S.), used in chronic *bronchial catarrh*,—dose, ℥ʒi to ℥ʒii. *Adeps Benzoinatus*, 2 per cent., U.S., contains only enough of the benzoin to preserve the lard, and is employed as the basis of ointments.

ANTIPYRIN.

Antipyrin was discovered by Dr. Ludwig Knorr, of Munich, and first experimented with by Professor Filehne, of Erlangen (*Zeitschrift f. Klin. Med.*, 1884, vii. 641). It is a grayish or reddish-white crystalline powder, of a slightly bitter taste, soluble in fifty parts of ether, much more so in water, ten parts of it being dissolved in six parts of cold water, and also very soluble in alcohol and chloroform. Its solution strikes with a solution of perchloride of iron a reddish brown color, with nitric acid a beautiful greenish color.* Chemically, it is known as *Phenyl-dimethyl-pyrazolone*. On account of its being a proprietary medicine, prepared by a patented process, it is not recognized by the U.S. Pharmacopœia, but is official in the British Pharmacopœia under the name of PHENAZONUM, *Phenazone*.

PHYSIOLOGICAL ACTION.—When given to the normal man in doses of from ten to twenty grains, antipyrin produces usually no distinct symptoms. If, however, it be administered in a larger dose, and especially if it be given in the continuous dose, so as to accumulate in the system, it causes languor, malaise, a peculiar cyanotic pallor of the face, with failure of the pulse. The symptoms which have in a number of cases followed large doses are very curious, and some of them difficult of explanation. Prominent among these symptoms is an eruption on the skin, which may occur without constitutional disturbance, but is often accompanied thereby. In its most typical form it consists of small, reddish, irregularly circular spots, resembling somewhat those of measles, and arranged in patches separated by sound skin. The red color usually disappears on pressure, leaving a brown pigmentation, which also comes into view during the fading of the exanthem, and ordinarily continues five or six days. In some cases the eruption is

* When antipyrin is dissolved in sweet spirits of nitre, a green color rapidly develops by the production of the *iso-nitroso-antipyrin* of Knorr. According to Professors H. C. Wood and John Marshall (*Therap. Gaz.*, Feb., 1889), the reaction is due to the presence of free nitrous acid in commercial sweet spirits of nitre. The same observers have shown that *iso-nitroso-antipyrin* is not toxic, in the rabbit three grains per pound, in the dog one grain and a half per pound, having no effect upon life.

erythematous; not rarely it resembles an urticaria in which the wheals may be made very prominent by a wide-spread, deep-crimson blush. In a case reported by Spitz (*Therap. Monatsch.*, 1887), the whole surface of the body was covered with bulla, which, becoming confluent, involved the skin in a universal, desquamative inflammation. Very frequently the antipyrin rash is accompanied by wide-spread oedema, which is especially prone to involve the face, causing great swelling, and even closure of the eyes, but which may be most pronounced in the extremities. The mucous membranes may share in the irritation. Violent catarrhal conjunctivitis is not very rare, whilst coryza and laryngitis have been noticed. (For cases, see *London Lancet*, vol. i., 1888; *British Med. Journ.*, vol. i., 1888; also vol. i., 1892.)

The marked rise of temperature which is apt to accompany the antipyrin eruption is probably due to the irritation of the skin and the subdermal tissue, and is not a direct result of the action of the drug, since, when the antipyretic eruption takes the form of an urticaria, the itching, sighing, hysterical unrest, and dyspnoea, which are apt to accompany urticarias not due to antipyrin, have been very pronounced.

In a number of cases of antipyrin-poisoning there have been violent nervous symptoms, which seem to be a direct outcome of the action of the poison. The vomiting, which is sometimes accompanied by abdominal pain, may be looked on as an evidence of local irritation; but this is hardly the case with giddiness, somnolence deepening into coma and passing into profound stertorous unconsciousness, with dilatation of the pupils, and epileptiform convulsions,—all of which have been noted (*Berlin. Klin. Wochens.*, xxvi., 1889; *Med. News*, liv., 1889; *Correspond. Blatt.*, 1888). The unrest, excitement, violent tremblings, not rarely seen, seem also to be directly produced by the drug. As illustrative of these symptoms may be cited the case reported by Dr. F. Spitzer (*Centralb. f. d. Therap.*, viii., 1890), in which a man, aged twenty-four, shortly after taking one hundred and twenty grains of antipyrin during an hour, complained of violent pain in the belly, and vomited freely; an hour later he was found in a condition of great excitement, screaming out, champing his teeth, with a red face, much swollen conjunctiva, and cold extremities; the pulse was one hundred and eight per minute, rhythmical, with strong heart-impulse; the respiration thirty-eight. There was præcordial anguish, pain in the stomach, and marked tremors, with exaggeration of the tendon-reflexes. Fifteen hours after the poisoning he was seized with a sudden chill, with marked cardiac failure, from which, however, he recovered. Dr. H. M. Briggs (*London Med. Rec.*, March, 1891) reports blackish urine with albumen and blood-corpuscles in antipyrin-poisoning.

The symptoms produced by antipyrin upon the lower animals resemble those caused in man, except in the absence of dermal irritation and its secondary results. According to the observations of Dr. Leon Arduin (*Thesis*, Paris, 132, 1885), Professor Demme (*Fortschritte der*

Medicin, 1884, ii. 657), Dr. Coppola (*Kobert's Jahresbericht*, 1885, p. 314), Simons and Hock (*Johns Hopkins Hosp. Bull.*, 1890), and others, in the frog, in moderate toxic doses (half to one centigrammo), it causes convulsions, with opisthotonos, and a very marked increase of reflex activity. In the earlier stages of this condition the animal is cataleptic, and L. Blumeneau (*St. Petersb. Med. Wochens.*, 1887) affirms that there is a primary stage of quiet with diminished reflex activity. If given in overwhelming amount, antipyrin causes in frog immediate quiet, muscular relaxation, with loss of reflex activity, deepening into complete paralysis and death. In mammals, the chief symptoms of antipyrin poisoning are ataxy, paraplegia, hurried respiration, convulsions with general rigidity, dilated pupils, unconsciousness, and fall of temperature,—all ending in death, which seems to be due to failure of respiration. Small therapeutic doses cause in the lower mammals, as usually in man, no pronounced symptom. In trying to trace out the physiological action of the drug, I shall discuss separately the different systems.

Nervous System.—The action of antipyrin upon the brain is not profound, but the quietude, the relief in certain motor and sensory nerve-storms produced by therapeutic doses in man, and the somnolence, stupor, coma, which have been noted in antipyrin-poisoning, both in man and animals, indicate that the drug has a *peculiar influence upon the cerebral cortex*. Testimony is strangely at variance as to the origin of the convulsions. Blumeneau and Batten and Bokenham (*Brit. Med. Journ.*, i., 1889) state that section of the cord does not prevent their occurrence in the posterior segment of the body; while Coppola and Simon and Hock state that it has such action. Either the first-named observers failed to make complete section, or else both cerebral and spinal convulsions are produced by the drug. At present it seems most probable that the convulsions are chiefly epileptiform,—i.e., cerebral; this is in accord with the statement that cramp-asphyxia (spinal spasm) is never produced by antipyrin. The cerebral action of the drug is further witnessed to by Simon and Hock, who believe that they have experimentally proven that it first stimulates and then paralyzes the special senses.

Our knowledge of the action of antipyrin upon the spinal cord is very incomplete. We do not certainly know whether the alleged primary decrease of reflex activity (Blumeneau), or the characteristic increase of reflex activity (various observers), or the final abolition of reflex activity, are or are not of spinal origin, although it is *probable* that in toxic doses the drug acts as a *primary stimulant and a secondary depressant of the spinal cord*. Choupe (*Semaine Med.*, July, 1887) states that the drug even has the power of suspending the strychnic convulsions. If the observations of Blumeneau—that in a frog with the cerebral hemispheres removed antipyrin produced alowness of reflex reaction, which immediately disappears upon section of the spinal

cord high up—be correct, the primary reflex depression is probably cerebral.

There seems to be no doubt that antipyrin *paralyzes the motor nerves*. Lepine (*Lyon Med.*, vol. liii.) has noticed that if access to the nerve be shut off, such nerve, after death from antipyrin, will be distinctly more active in its response to stimuli than is the implicated nerve; whilst Simon and Hoek (*Johns Hopkins Bull.*, 1890) noted in frogs killed with antipyrin the motor nerves absolutely paralyzed, and have also demonstrated the influence of the drug by bringing it in local contact with an exposed nerve. These latter observers confirm the earlier work of Coppola, and it seems to be proven that when applied locally, or given internally, antipyrin is a distinct *depressant of the sensory nerve-trunks*. Simon and Hoek affirm that in the beginning of the convulsive stage animals can be operated upon without the use of an anæsthetic. In accordance with this are the observations of Batten and Bokenham (*British Med. Journ.*, i., 1889), that when locally applied to the exposed intestine, antipyrin prevents the peristaltic wave which is normally produced by the application of common salt, although it does not check the annular contraction at the point of irritation; an effect which seems only explainable by the supposition that the intestinal nerves and not the intestinal muscles are paralyzed by the drug.

Various observers have noticed in antipyrin-poisoning more or less pronounced muscular stiffness; and Devraux-Armand has seen it pass into post-mortem rigidity in animals fatally poisoned (*Thesis*, Nancy, 1885). This stiffness appears to be the result of an action exerted directly upon the muscles; for in Armand's researches the muscles removed from the body of the animal killed with antipyrin underwent much more powerful and prolonged contraction than was produced by the same amount of stimulation in the normal muscle.

Circulation.—Further researches in regard to the action of antipyrin upon the circulation are very desirable, but there are certain points concerning which we have definite knowledge. Arduin, Demme, Lepine, and Armand all affirm that in the poisoned frog the heart is arrested in diastole, but Coppola states that antipyrin has no influence upon the circulation in the frog, that in many cases after the largest dose the heart is arrested in systole, and that in the Williams apparatus no effect is produced by antipyrin upon the isolated heart unless the dose be enormous. Favat found, however, that while moderate doses have little effect, large doses diminish the frequency and force of the cardiac contractions in the isolated heart of the frog, and finally cause diastolic arrest (*Thesis*, Lyons, 1887), and I think it must be considered established that in *sufficient dose antipyrin acts as a direct paralyzant to the frog's heart*. Demme, Arduin, Armand, and Henry Casimir (*Thesis*, Lyons, 1886), Cerna and Carter (*New Remedies*, 1892), have separately determined by experiment that in moderate doses antipyrin *increases the arterial pressure*, while *toxic doses lower the pressure*. The

cause or causes of the rise have not yet been fully determined; it occurs in curarized animals, and is therefore independent of any action of the drug upon the respiratory centres. According to Cerna and Carter, it is not prevented by previous section of the pneumogastric nerves and of the spinal cord, and the pulse-waves accompanying it are of extraordinary size and height. It would appear, therefore, that it is at least in part due to a *direct stimulation of the heart*.

The action of the drug upon the vaso-motor system is at present writing very doubtful. Cerna and Carter affirm that it has no influence upon the blood-vessels, but certainly give no proof of this; and the fact ascertained by Casimir, that the rise of arterial pressure is accompanied by a distinct decrease in the size of such vascular internal organs as the kidneys, indicates that the drug produces a vaso-motor spasm, a view which receives confirmation from the assertion of Arduin, that antipyrin is a powerful hæmostatic. On the other hand, Querrolo, employing the plessimograph of Mosao (quoted by Armand), found that the arm is increased in size under the influence of antipyrin, and therefore that the peripheral vessels are dilated, and Casimir affirms that similar dilatation can be seen in the blood-vessels of the ears of rabbits poisoned by antipyrin.

The fall of the arterial pressure is without doubt, at least in part, the result of a depressing influence of the drug upon the heart itself; but if the observation of Bettelheim (quoted by Dr. A. Biach, *Die Neueren Antipyretica*), that during the fall of blood-pressure the temperature of the interior of the body notably falls, while that of the exterior correspondingly falls, be correct, vaso-motor paralysis probably is also a factor.

According to the researches of Cerna and Carter, the pulse is usually increased in rate by full doses of antipyrin through a paralytic influence upon the inhibitory nerves, but afterwards becomes decreased in number through the direct action of the drug upon the heart itself.

The peculiar lividity often seen in persons under the influence of antipyrin is probably due to changes in the blood itself. According to Lepine, methæmoglobin is largely formed during the poisoning, but Crolas and Hagoumeng failed to detect it (*Lyon Méd.*, 1889). The three observers are in accord in finding that the number of the red corpuscles is not perceptibly affected, even by the continuous exhibition of very large doses.

Respiration.—Therapeutic doses of antipyrin do not seem to have distinct influence upon the respiration, but Simon and Hock have noticed after toxic doses great increase in the respirations, followed by a marked decrease. In the guinea-pig, Batten and Bokenham have seen Cheyne-Stokes breathing. According to Simon and Hock, the *primary respiratory increase* is not prevented by section of the vagi, and is, therefore, *centric*.

Absorption and Elimination.—The absorption of antipyrin is very rapid, and although Carrara (quoted by Buch) failed to detect it in the urine of a dog that died two hours after the ingestion of fifteen grammes, its elimination seems to be usually prompt and rapid. The chief channel of escape is the kidneys; I. I. Hage (*Kobert's Jahresb.*, 1885) was unable to find the drug in the sweat or the saliva, but it has been found in minute quantities in the milk of nursing women by Pinzani (*Centr. für die Ges. Therap.*, Aug. 1890). Armand states that it can be continuously detected in the urine from twenty-five minutes to thirty-six hours after its ingestion, although most of it is eliminated in the first twelve hours. MM. Perret and Givro (*Le Bull. Méd.*, Aug. 1891) found that urinary elimination begins in the adult or in the child three-quarters of an hour to an hour after the ingestion, but that the child eliminates the antipyrin more rapidly than the adult. According to Maragliano (*Kobert's Jahresb.*, 1895), the elimination is at its height in four hours, and continues for a day and a half. The urine is sometimes increased, sometimes diminished, in quantity; it is normal in appearance, and never contains albumen or sugar.*

The question whether all of the antipyrin escapes unchanged is not as yet answered. Capitan and Gley (*Compt. Rend. d. Soc. d. Biol.*, iv. 1887) found that the action of the drug is much less intense when it is thrown into the mesenteric vein than when it is given by injection under the skin or into the peripheral vein. Their theory, that the liver retains or modifies antipyrin, is made more plausible by the researches of Dr. Wera Iwanoff (*Archiv f. Physiol.*, 1887, Supl. Bd.), who finds that the liver-cells of frogs poisoned with antipyrin undergo very pronounced changes in their nuclei and protoplasm. The statements of Iwanoff are especially important in connection with the known effect of antipyrin upon urea elimination. Disturbances of the hepatic function may be at the basis of the inhibitive action of the drug upon urea formation.

Temperature.—When given in large doses to the normal animal, antipyrin frequently, but not invariably, produces fall in the bodily temperature; in the fevered animal the fall of temperature is more marked and more constant. The cause of the fall cannot be considered to be entirely established, but it is probably the result of an influence exerted directly upon the thermogenetic centres. It is certainly independent of any action upon the general circulation, as I have seen the temperature of fevered dogs reduced four or five degrees by antipyrin without change in the arterial pressure. In seven out of nine experiments made by Drs. H. C. Wood, E. T. Reichert, and Hobart A. Hare† (*Therap. Gaz.*,

* This statement I have allowed to stand from the old edition, and it is probably correct except in its absoluteness. Dr. E. L. Tompkins has, however, reported a case in which the continued use of antipyrin in enormous quantities produced albuminuria (*Virginia Med. Monthly*, xviii.).

† The course of fever produced by injections of pepsin in the blood varies, and in calorimetric experiments it is not sufficient to give pain and when the temperature has risen

ii. 803) upon normal animals, there was a decrease in both the production and the dissipation of animal heat. In two experiments both functions were distinctly increased. When tetanic convulsions occur from antipyrin there is a marked rise of the bodily temperature. In both of the two calorimetric experiments in which the heat-production was increased, very large doses of antipyrin had been given, and it is believed that the animal suffered convulsions in the calorimeter. In almost all the experiments the decrease of heat-production was very much greater than the decrease of heat-dissipation: it would appear, therefore, that antipyrin in the normal dog primarily lessens heat-production, the fall of the heat-dissipation probably being the result, at least in part, of the lessened heat-production. In experiments upon dogs in which fever had been produced by injections of pepsin, both heat-production and heat-dissipation were markedly decreased, but usually heat-production was more affected than heat-dissipation. The experiments of Destree (*Journ. de Med. d. Clin. d. Pharm.*, 1888, lxxxvi.) and of Engel (quoted by Biach) are, so far as they go, in accord with those just given, whilst Cerna and Carter found pronounced decrease of heat-production with simultaneous increase of heat-dissipation in dogs febrile by injections of putrid blood; so that it would appear that antipyrin reduces temperature in fever by decreasing the heat-production.* That antipyrin acts through the nervous system is strongly indicated by the influence which it has over fever produced by nerve lesions. Dr. P. J. Martin (*Ott's Modern Antipyretics*, 1891), Dr. R. Gottlieb (*Arch. f. Exper. Path. u. Pharm.*, Bd. xxvii., 1889), and Dr. H. Girard (*Revue Med. d. l. Suisse Romande*, vii., 1887) are in accord in finding that the rise of temperature which is produced in the rabbit by punctures in the neighborhood of the striate body is lessened or altogether put aside by antipyrin. Martin has further found that heat-production is also lessened under these circumstances. Gottlieb states that Sawadowski has determined that in the dog, whose spinal cord is cut high up, antipyrin no longer reduces the temperature (*Centralb. f. d. Med. Wissensch.*, 1888).

The studies which have been made by chemists as to the effects of antipyrin upon the elimination of waste products, taken in the

administer the antipyretic and study calorimetrically the result. The best way is to produce a paroxysm of fever on one day and study it calorimetrically through its whole course; some days subsequently, the same animal and dose of pepsin being used, the course of the fever is to be modified by the antipyretic, and the heat-dissipation and heat-production of the two days contrasted.

* The experiments of Gottlieb, however, are not consonant with this view: in three experiments hypodermic injections of antipyrin were followed by increased heat-production, with a greater increase of heat-dissipation and consequent fall of temperature. Similar results were also reached in rabbits in which fever had been produced by pricking nerve-centres (*Archiv f. Exper. Path. u. Pharm.*, xxviii., 1891). These experiments are certainly open to the objection that it is not shown that the changes in heat-dissipation and production which were noted were really produced by the antipyrin, and were not due to the confinement in the calorimeter or to the natural variations in the course of the fever itself; in other words, there were no proper control experiments.

whole, are in accord with the view that antipyrin lessens heat-production. It is indeed true that Chittenden and Cummins (*Physiol. Labor. Shof. Sci. School*, vol. ii.) were unable to find that antipyrin, either in large or in toxic doses, has any effect upon the elimination of carbonic acid by the animal; but before these results can be considered as established, further experimentation is necessary. Again, Armand thought that he had chemically proven that antipyrin increases the elimination of urea, but the original studies of Umbach (*Arch. f. Exper. Path. u. Pharm.*, xxi.), who found that large doses of antipyrin very markedly decrease the elimination of urea, have been so abundantly confirmed* that it would seem that it must be considered established that antipyrin, both in health and in fever, diminishes the output of the nitrogenous products of tissue-waste.

It would further appear probable that antipyrin alters the normal relation between the various excrementitious substances, since Umbach has found that while the urea was markedly diminished, uric acid was scarcely altered; and Robin affirms that in his experiments the elimination of uric acid was even augmented.

Antiseptic Influence.—The influence of antipyrin upon pathogenetic micro-organisms, and upon fermentation, has been elaborately studied by Engel (quoted by Biach), who found that such influence is so exceedingly feeble as to have for practical purposes no existence. On the other hand, Professors Chittenden and Stewart state that antipyrin inhibits, and if present to the amount of three per cent. stops, the digestive action of the acidulated pepsin solution, whilst Cazeneuve and Visbeck (*Lyon Méd.*, 1892) find that one per cent. of antipyrin is sufficient to indefinitely put off putrefaction of the blood. They also confirm the fact that antipyrin is capable of inhibiting the action of ferments like pepsin and diastase. Roux and Rodot (*Lyon Méd.*, 1892) find that a four-per-cent. solution is sufficient to very sensibly affect the *Bacillus coli communis*.

Local Effects.—It is claimed that antipyrin is one of the most powerful hæmostatics known, its forty-per-cent. solution exerting a most active constricting influence upon the blood-vessels when locally applied. Huchard and Henocque (as quoted by Armand) state that when they cut off the feet of guinea-pigs and put the stumps into a solution of antipyrin, tincture of chloride of iron, etc., the bleeding was arrested most quickly by the antipyrin. It has already been pointed out (see page 696) that antipyrin is a paralyzant to sensory nerves, and it is claimed that it is a practical local anæsthetic, especially useful

* Among the chemists who have reached this conclusion by practical experimentation may be mentioned Wiczkowski (quoted by Umbach), Walter, of St. Petersburg (*Therap. Gaz.*, vol. ii.), F. Müller (*Jahresb. für Thierchemie*, xii.) Ries (quoted by Biach), Albert Robin (*Bull. Acad. Méd.*, xviii., 1887), and Jacobovitch (*Brit. Med. Journ.*, li, 1888). Tanak's (*Schmidt's Jahrb.*, Bil. cccxxvi) failure to get a pronounced effect may have been due to his having used too small doses.

in irritation of the larynx. Dr. Saint Hilaire (*Journ. Laryng., Otology, etc.*, 1892) affirms that the anæsthesia produced by antipyrin is complete and generally lasts from one to two hours; that the sensibility to touch and also to heat and cold is destroyed, the thermal sense returning first; also, that the solution must not be of less strength than thirty per cent., twenty-per-cent. solutions having no anæsthetic effect.

Summary.—Whilst the ordinary dose of antipyrin produces no distinct symptoms, when in large enough amount the drug causes languor, malaise, cyanosis, depression of the circulation, giddiness, somnolence, epileptiform convulsions, a measles-like exanthem, coma, and collapse. Owing to idiosyncrasy, it provokes in some cases violent urticaria and subdermal inflammation, which may be accompanied by fever and other constitutional disturbances. It is probably a primary stimulant and a secondary depressant of the motor spinal cord. It is certainly a paralyzant to both the motor and sensory nerve-trunks, and seems to have also some action upon the muscles themselves. A small dose may moderately increase arterial pressure by direct stimulation of the heart; and there is some reason to suppose that the drug also stimulates the vasomotor system, but this is not established. The final fall of arterial pressure is certainly due, at least in part, to a direct action upon the heart. In sufficient amount antipyrin causes methæmoglobin to appear in the blood. It increases the respiratory rate by a centric action. It is absorbed rapidly, and eliminated rapidly, at least in part, unchanged. It probably lessens the production of animal heat by a direct action through the nervous system, independent of any influence upon the circulation, and appears also to stimulate heat-dissipation. Both in health and fever it diminishes the output of the nitrogenous products of tissue waste.

THERAPEUTIC ACTION.—When antipyrin is given to a healthy man in a dose of half a drachm, it usually produces no marked symptoms, except some ringing in the ears, slight nausea, and an uncertain fall of bodily temperature, which very rarely, if ever, amounts to more than one-tenth of a degree. After doses of a drachm or upwards, vomiting is very apt to take place, accompanied or preceded by giddiness and distress in the head. In fever cases, about half an hour to an hour after a dose, profuse sweating occurs, and it is at this time that the fall of temperature takes place. It does not appear, however, that the latter is produced by the diaphoresis. At least, according to Carl von Noorden (*Berlin. Klin. Wochens.*, 1884, p. 523), the sweating can be arrested by the use of hypodermic injections of atropine or agaricin without affecting the fall of temperature. Moreover, the sweating is not invariably present, and in dogs, which do not sweat, antipyrin is a powerful antipyretic in fever. According to most authorities, the depression of temperature lasts longer than that caused by some other antipyretics, continuing from two to ten hours. It is accompanied by a reduction of the rate but not of the force of the pulse. In some cases the sweating

is not profuse, and it is probably under such circumstances that observers have noticed a markedly increased diuresis. Usually the patient is more comfortable under the action of the drug than at other times; sometimes, however, there is distressing vomiting.

Antipyrin may be employed as an antipyretic in almost any disease accompanied with high temperature, such as *pneumonia*, *erysipelas*, and *typhus*, *scarlet*, *yellow*, and *typhoid fevers*, *rheumatism*, etc.: it has also been freely given in the hectic fever of phthisis, but various observers state that in such cases it produces so much feebleness and general depression as to forbid its use. Nevertheless, my own observation is that when used with caution in phthisis it often gives great relief. In *typhus fever* it reduces the temperature, but in a number of recorded cases it has caused very serious collapse. It appears to have some specific action in rheumatism, but does not in this respect equal salicylic acid. According to A. Pribram (*Prager Med. Wochenschr.*, 1884), in *pneumonia* the frequency of the respiration is distinctly lessened by it, but this is probably due simply to the lowering of the bodily temperature. In children it has been used with asserted good results by a number of clinicians, and it appears to be especially useful in the pneumonia and bronchitis of the young.

The second indication for the meeting of which antipyrin is sometimes used with success is the *relief of motor disturbance*. Over the minor spasmodic conditions of *hysterical* origin, over *chorea*, etc., antipyrin has a certain amount of power. In 1888, Sonnenberger (*Therap. Monatsch.*, vol. ii.) commended it very highly in *whooping-cough*, stating that if given at regular intervals it greatly lessens the number of paroxysms, or even aborts the disease; and further clinical experience seems to show that the drug has real value. M. A. Chouppe states that antipyrin has great power in relieving uterine pains after parturition or in *dysmenorrhœa*, and that if it be given during labor along with ergot it allows the contractions to go on, but renders them painless. In more severe spasmodic disorders antipyrin sometimes does good. It is certainly worthy of trial in *tetanus*, especially when the temperature is high. It may be given in *epilepsy* with some hope of success, since its influence in preventing the return of convulsions is sometimes extraordinary, although in the great majority of cases it fails entirely. I have studied it in a large number of cases, but am unable to point out any indications which will warrant in an individual case an *a priori* opinion that antipyrin will do good. The only method is that of trial. Not less than forty-five grains a day should be given, and if, after a time, no cyanosis or muscular weakness mark the physiological action of the drug, and the convulsions still recur, the dose should be increased up to the physiological limit. The combination of antipyrin with bromide of ammonium affords much better results than either drug alone, and I have given to a large number of cases fifteen grains daily of the antipyrin in this combination for many months, and even for years, without

cumulative action or perceptible effect upon the general nutrition or the general nerve functions. Antipyrin has been used with alleged success in *laryngismus stridulus*, in *nocturnal emissions*, in *asthma*, and in *urinary incontinence* of children.

The third indication which may sometimes be advantageously met by antipyrin is the *relief of pain*. In April, 1887, M. See announced to the French Academy of Medicine that antipyrin is a powerful analgesic, which when given in doses of from forty-five to ninety grains a day will control almost all forms of pain. Such doses, however, border upon toxic, and are rarely justifiable. Moreover, they are scarcely ever necessary in properly-selected cases. Abundant clinical experience has shown that antipyrin for the relief of ordinary inflammatory pains is not reliable, and is in every respect inferior to opium; but that it is a very valuable agent against various nervous pains, sometimes giving much more relief than opium, and usually causing less disturbance to the system. Especially is it effective in *rheumatic pains*; and in *migraine* and other forms of *neuralgia* in which the pain is the outcome of nerve-storm; it will, indeed, often control the pangs of *locomotor ataxia*; I have even seen it abort a *gastric crisis*. Whether it acts by a true analgesic influence, or whether it simply puts aside the nerve-storm which is the cause of the pain, is entirely unknown. In violent *hemicrania* sleep follows relief; but antipyrin is not a true hypnotic. Antipyrin is stated to greatly increase the analgesic effects of morphine.

Antipyrin has also been used in various disorders not included under the indications already given. Thus, Dr. M. H. Feeny (*London Lancet*, 1889) reports *subacute Bright's disease* cured by it; Dr. Clement (*Lyon Med.*, 1891), that it is of value in bringing about absorption of *pleuritic effusions*. Both in *diabetes mellitus* and *diabetes insipidus* it has been used with asserted good results. Dr. Saint-Phillippe commends it highly in *infantile diarrhœa* with indigestion and pain (*Journ. de Méd. de Bordeaux*, 1891). Dr. Salemi affirms that it is an active and practical *antigalactagogue*, and in this has been confirmed by Dr. Ryan-Tennison and by Guibert (*La Semaine Méd.*, 1891).

Antipyrin may be administered hypodermically, by the mouth, or by the rectum. The dose for a child of one or two years of age may be set down as two to three grains; for a child five years old, three to seven grains; for the adult the dose should not exceed twenty grains, and ten is usually sufficient, in fever cases repeated every one or two hours until forty grains are given, or sweating comes on, or the temperature falls. In children it would not be safe to repeat the dose more than once. Some authorities prefer a single large dose of from forty to sixty grains in the adult.

Hypodermic Use.—Antipyrin has been used to a considerable extent hypodermically for the relief of pain, and in neuralgias and nerve-pains good can sometimes be achieved by its local influence. The

burning pain produced by the injection of a thirty-per-cent. solution usually lasts only a few minutes, and is not followed by local inflammation. Verneuil, however (*La Semaine Méd.*, 1891), has reported partial gangrene of the foot following and apparently produced by a hypodermic injection of antipyrin for the relief of sciatic neuritis.

TOXICOLOGY.—In describing the action of antipyrin upon the normal human organism, sufficient has been said in regard to the general symptoms produced by poisonous doses. It seems necessary, however, to point out that these symptoms in a large proportion of recorded cases seem to have been due to constitutional peculiarities of the individual rather than to the use of very large doses of antipyrin, and they are rarely, if ever, attended with any danger to life. Thus, E. W. Young (*New York Med. Rec.*, 1890) reports a serious poisoning by six grains of antipyrin. Theo. Schwabe reports (*Deutsch. Med. Zeit.*, 1890) a case in which fifteen grains of antipyrin, given to a young woman for neuralgia, produced violent poisoning with collapse, complete amaurosis, cyanosis, urticaria, etc. Almost equally inexplicable are those cases which have especially occurred in typhoid and other fevers, in which fatal depression has been produced by doses of antipyrin that were not larger than have frequently been used without evil results. Thus, in Dr. Barrs's case (*London Lancet*, 1885, Feb. 28), thirty-five grains of antipyrin were given to a puerperal woman with a temperature of 103.6°, and followed in three hours by half the quantity, after which the temperature sank to 98°, and, in spite of stimulation, death occurred thirty-two hours later. Our knowledge of the physiological action of antipyrin seems to negative the supposition that the depression in these fever cases is due to any direct action upon the heart or other vital organ. Heat is a stimulant to function, and it may well be that the cause of the collapse is the sudden fall of bodily temperature in a person whose nervous system is excessively enfeebled by a fever of typhoid nature.

ACETANILIDUM—ACETANILID.* U.S.

Antifebrin, or *phenylacetamide*, is an anilin in which one atom of hydrogen has been replaced by the radical acetyl; or it may be considered as an ammonia in which one atom of hydrogen is replaced by phenol and another atom by acetyl. It is a white, crystalline substance,

* *Monobromoacetanilid*, a compound made by the introduction of a bromide atom into a molecule of acetanilid, has been tried therapeutically by Drs. Bokenham and Jones (*British Med. Journ.*, 1890). Seven and a half grains of it produced marked cyanosis, giddiness, intense headache, violent cardiac pain resembling that of an angina, loss of consciousness, great feebleness, feeble rapid pulse, mitral systolic murmur. *Eucalyne* or *Methylacetanilid* is a tasteless powder, scarcely soluble in water, which in toxic doses produced in animals loss of sensation, violent cramps, and death from asphyxia. It has been used to a considerable extent as an antipyretic, and for the relief of pain in doses of from five to ten grains taken during the twenty-four hours; but it seems to be distinctly inferior, in certainty, pleasantness, and safety of action, to acetanilid (*Schmidt's Jahrb.*, lld. cccxiv., 1889, although some clinicians prefer it (*Lancet*, May, 1892).

entirely without odor, having a bitter, mildly piquant taste. Whenever it gives a reddish-orange precipitate with sodium hypobromite, it should be rejected as containing anilin. It is soluble, at 59° F., in one hundred and ninety-four parts of water and in five parts of alcohol, in eighteen parts of boiling water and 0.4 part of boiling alcohol; very soluble in ether and chloroform.

The medical virtues of antifebrin were first discovered by Cahn and Hepp, and have been abundantly confirmed by numerous observers. When given to healthy men in doses of seven to ten grains it usually produces no appreciable effect. The repetition of this commonly causes somnolence, constipation, occasionally headache or nausea, *qualaise*, and a peculiar cyanotic condition of the face and extremities. When given to persons suffering from fever in doses of ten grains there is usually in about an hour fall of temperature, which reaches its maximum in two or three hours and may continue from six to seven hours. In some cases at this time the cyanosis is apparent; usually, but not always, the fall of temperature is accompanied by a profuse sweating, which is generally described by clinicians as being less than that produced by corresponding doses of antipyrin. The fall of temperature is not dependent upon sweating, since it sometimes occurs without the sweating, and Dr. G. Pavai-Vajna (*Centralbl. Gesammte Therapie*, 1887) finds that the sweating can be arrested in great part by atropine without interfering with the thermic action of the drug. In rare cases the lowering of the bodily temperature has been coincident with the occurrence of collapse. Armin Hugher (*Corresp.-Blatt für Schweizer Aerzte*, 1887, xvii.) records a case in which there was an eruption evidently similar to that commonly produced by antipyrin. The spots were small, but especially abundant upon the face and forehead, and of a dark-red color. Mydriasis and deafness, with ringing in the ears, have been noted occasionally by other observers. Collapse appears to be less frequent than with antipyrin. The experiments of Dr. Hobart A. Haro (*Therap. Gaz.*, 1887) show that at present inexplicable cardiac failure may occur suddenly.

In the experiments of Herczel (*Wien. Med. Wochenschr.*, 730, 1887), the symptoms produced by fifteen to twenty grains in rabbits were loss of the reflexes, tremors deepening into periodic convulsive movements, great fall of temperature, frequent, irregular, superficial respiration, retention of urine, coma, and general paralysis, ending, if the dose had been large enough, in death, which could not be prevented by artificial respiration. The heart was arrested in diastole. After the prolonged action of the drug there was fatty degeneration of the heart, liver, and kidneys. Weill noticed (*Bull. Therap.*, cxii. 150; also *Thesis*, Paris, 1887), in addition to these symptoms, an *anæsthesia*, which in the later stages of the poisoning was almost complete.

Notwithstanding the number of papers written concerning antifebrin, our knowledge of its physiological action is very incomplete.

The cause of the convulsions does not seem to have been determined. The coma which is present in the advanced stages of the poisoning indicates that, directly or indirectly, antifebrin affects the cerebral function, but consciousness is stated by experimenters to be preserved at a time when the lower portion of the nervous apparatus is distinctly affected. According to the experiments of Professor Bokai (*Deutsch. Med. Wochen.*, Oct. 1887), antifebrin *paralyzes motor-nerve endings* of the frog's muscles in a manner similar to curare, and when brought in contact with the muscle itself for a sufficient length of time destroys its capability of contraction. In the poisoned animal just before death the muscles respond, however, actively, although irritation of motor nerve trunks fails to elicit response. Usually when antifebrin is given to patients with fever there is a fall in the pulse-rate corresponding to the fall of temperature. The size of the pulse is also reduced, and it may even become thready. Weill has found that, injected into the frog, the drug causes at first an acceleration of the heart's beat, with apparent increase in the force of the impulses, followed after a time by slowing and irregularity of contraction. In the earlier stage the size of the pulse-wave is increased and the respiratory curve is more accentuated; later the pulse-oscillations diminish, and become irregular and quickened, and if the dose has been large enough the manometric writing resembles that produced by asphyxia. In the earlier stages of the action there is a slight rise in arterial pressure.

The cyanosis of antifebrin-poisoning has been thought to be due to the formation of methæmoglobin, but in a case of violent poisoning with excessive cyanosis, Freund was unable to detect anything abnormal in the blood, by microscopical or spectroscopical examination (*Deutsch. Med. Wochens.*, xiv., 1888). Dr. Herczel states that the red corpuscles do not adhere in rouleaux, that they are somewhat granular, and that, when the drug is given to dogs for a length of time, the blood is less alkaliescent than normal, and contains in its serum dissolved coloring-matter. According to Lepine and Aubert (*Gaz. Méd. de Strassb.*, i., 1887; also Herczel), the oxygen of the blood is distinctly decreased.

Elimination.—According to Drs. Pavai-Vajna and Kumagawa (*Virchow's Archiv*, cxiii., 1888), antifebrin is eliminated in the same manner as anilin,—namely, as *paramidophenol sulphate*. Matusorszky is stated to have obtained the reaction of this substance in the urine not only when antifebrin had produced cyanosis, but in every case in which it had been given at all. This method of elimination indicates that the antifebrin breaks up in the organism into acetic acid and anilin, and that the anilin is then oxidized into paramidophenol, which unites with sulphuric acid.* Cann and Hepp, however (*Le Progrès*

* The changes which occur in antifebrin in the system have led to the theory that its medical virtues are dependent upon the liberation of anilin in the blood. The symptoms produced by antifebrin are certainly similar to those caused by anilin. Thus, Dr. Herczel states that in a case of anilin-poisoning the symptoms were colossal cyanosis, sweating, vomiting,

Méd., Jan. 1887), affirm that antifebrin escapes finally with the urine in great part unaltered, and that only a small portion of it is converted into anilin and acetic acid; but Müller as well as Kumagawa states that antifebrin cannot be found at all in the urine, and consequently that it undergoes entire decomposition. Drs. Jaffe and Hilbert (*Zeitschr. f. Physiol. Chem.*, 1887-88, xii.) found that in dogs acetanilide passes off chiefly as o-oxycarbonol and as paramidophenol, both united with glyco-uronic and sulphuric acids; in rabbits, chiefly as paramidophenol, paired with the acids. It is probable that the proportion of antifebrin which is decomposed varies with the size of the dose and the condition of the system.

Kumagawa found that while small doses had no definite effect, large doses enormously increased the nitrogenous elimination; but in Lepine's experiments the result varied, there being sometimes an increase and sometimes a diminution; while H. C. Taylor obtained a slight increase (*Lab. Physiolog. Chem.*, Yale, Jan. 1889). According to Kumagawa, antifebrin exerts a strong antiseptic influence upon intestinal changes, decreasing the bacteria in the intestines, and the urinary indican.

Temperature.—Attempts to decide the method in which antifebrin influences the bodily temperature have been made by Dr. H. A. Hare and E. M. Evans (*Therap. Gaz.*, 1887). In fifteen experiments upon normal animals, which in nearly all cases were allowed to run free, Dr. Hare obtained a distinct fall of temperature from antifebrin,—a result confirmed by Dr. Evans, but not in accord with the results of Cahn and Hepp, who found that antifebrin had not a constant influence upon the temperature of the normal animal. Dr. Hare, employing the calorimeter used by myself, found that in the normal animal heat-dissipation and heat-production were variously affected, in some cases being notably increased, in other cases notably decreased, and in others not distinctly altered. Dr. Evans, employing the D'Arsonval calorimeter, also reached various results. In eleven experiments heat-dissipation was decreased nine times, while heat-production was increased four times and decreased five times. In examining the records of the calorimetric experiments made by Drs. Hare and Evans on the normal animal, I find that not only did the rectal temperature *not fall* under the influence of antifebrin, but in nearly every instance there was a very distinct rise, amounting in some cases to over a degree. It is evident, therefore, that these experiments cannot be used to explain how antifebrin reduces temperature when it does cause a fall. The attempt to reason how a certain result is produced by a remedy from experiments in which that result was not produced is necessarily futile.

In Dr. Hare's experiments made upon dogs in which fever was caused by the injection of pepsin, antifebrin failed to produce any con-

tinuitas aurium, dyspnoea, fixedness of pupils, disturbances of sensibility, and a temperature-fall of 5.3° C., accompanied by a marked decrease in the coloring-matter of the blood and of the number of red blood-corpuscles.

stant fall of the bodily temperature, probably because the dose was not large enough. In the calorimetric studies heat-production was usually decreased, but sometimes it was increased,—an assertion which is also true of heat-dissipation. These experiments must likewise be laid aside, because there was no fall of temperature caused by the antifebrin. In Dr. Evans's experiments with fever produced by the injection of albumose, the antifebrin nearly always caused a distinct reduction of temperature. In the calorimetric studies the results obtained were constant, there being in each of the six consecutive experiments a decrease in both the hourly heat-dissipation and the hourly heat-production, the amount of decrease seemingly bearing some relation to the fall of temperature. It is plain that a decrease of heat-dissipation would have a natural tendency to elevate bodily temperature, and therefore the fall of temperature must have been due to the decrease of heat-production, which in turn gave rise to the decrease in the heat-dissipation. The experiments of Dr. Evans, therefore, so far as they go, indicate that in fevered animals *antifebrin produces a fall of the temperature by decreasing heat-production*.

THERAPEUTICS.—The medical application of antifebrin appears to be exactly parallel to that of antipyrin. There is some reason for believing that it is less apt than is antipyrin to produce collapse, or painful eruptions upon the surface, or other disagreeable effects. This may, however, simply be because it has been less freely used than antipyrin, since it is certainly capable of having any of these actions. Thus, Quast (quoted by Biach) reports a case in which cyanosis, collapse, and death were produced by it in a child; Dr. Marichaux (*Deutsch. Med. Wochens.*, xv., 1889) one in which four grains caused in a child five months old intense cyanosis, fixed pupils, coldness of extremities, rapid, almost imperceptible pulse, very superficial breathing, great sweating, complete unconsciousness, final recovery. Dr. Doll (quoted by Biach) gives a case in which about a drachm produced in a woman vomiting, cold sweat, intense prostration, great coldness of the extremities, dilated pupils, rapid irregular heart-action, without complete loss of consciousness. According to Sembritzki (*Therap. Monats.*, iii., 1889), the drug acts very badly on pregnant and nursing women. Antifebrin may be substituted for antipyrin for the reduction of temperature in fever, for the relief of pain, and for the prevention of epileptiform attacks. Dose, five to fifteen grains.

According to Lepine (*Lyon Med.*, vol. xlv., 1886), it will relieve not only the fulgurant pains of spinal disease, but also the tremors produced by multiple sclerosis, and it is often useful in *epilepsy*.

PHENACETIN.

Phenacetin, or *Acetphenetidin*, an acetyl derivative of amidophenol, crystallizes in tasteless, colorless needles, slightly soluble in water, more so in alcohol. It was first experimented upon by O. Hinsberg and

A. Kast (*Centralbl. f. Gesamt. Therap.*, April, 1887), who found that when given to dogs in doses of fifteen-hundredths to two-tenths of a gramme per kilo it has no effect, but in very large doses produces vomiting, irregular gait, hurried respiration, and somnolence, followed by general cyanosis and discoloration of the blood, due to the formation of methæmoglobin. Mahnert (*Deutsch. Med. Wochens.*, xiv., 1888) states that the muscular weakness produced by phenacetin is of spinal origin, and that in massive doses the drug is antagonistic to strychnine; also, that both respiration and heart are paralyzed by it. According to the same observers, it is chiefly eliminated unchanged; and the urine gives a positive Trommer's reaction, although containing no sugar. In the experiments of Ledoux it was found that phenacetin has scarcely any influence upon the isolated frog's heart. In the dog, however, in sufficient doses it seemed to have a direct action upon the heart itself (*Revue de Méd.*, Paris, xii., 1892). In a series of calorimetrical experiments, Dr. Ott (*Journ. Nerv. and Ment. Diseases*, xv., 1888) found that phenacetin pronouncedly decreases heat-production without producing distinct alteration of blood-pressure, and, therefore, probably acts as an antipyretic by lessening the heat-production through an influence upon the nervous system.

THERAPEUTICS.—Phenacetin has been largely used as an antipyretic, and for the relief of pains of such character as antipyrin is employed against. Dr. H. Hoppe (*Therap. Monats.*, ii., 1888) reports a case of a student who took thirty grains in a day, which produced some sleepiness, slight ptialism, slight weakness, some uncertainty of position in standing. The only serious case of poisoning that I know of by it is that recorded by Dr. Hollopeter (*Med. News*, 1889), in which a woman took twenty-two and a half grains in six hours, producing collapse, with marked lividity, great dyspnoea and restlessness, cold perspiration, slightly dilated pupils, ending in recovery.

There can be no doubt of the efficiency of phenacetin, and it would appear that it more rarely produces unpleasant symptoms than antipyrin, though urticaria has been noticed after its exhibition (Mahnert). If the statements of Crombie (*Pract.*, xliii., 1889) and of Hirschfelder (*Deutsch. Arch. f. Klin. Med.*, xliv., 1888-89)—that it acts more gradually than other antipyretics, and that its influence does not reach its maximum for three or four hours—be correct, phenacetin is probably the most valuable of the antipyretics, especially as it seems to be the least poisonous. Dose, from ten to twenty grains (0.65-1.3 Gm.). Phenacetin is highly commended by Dr. M. H. Lee as a local antiseptic dressing (*Memphis Med. Monthly*, xii., 1892).

PHENOCOLL HYDROCHLORIDE.—Phenocoll occurs in white needle-like crystals; it is made by the action of glyccoll upon phenetidin. Its hydrochloride is a white, finely-crystalline powder, very soluble in water.

PHYSIOLOGICAL ACTION.—The action of phenocoll upon the animal organism is not very marked, Von Mering having found that twenty-three grains of it will not produce any pronounced symptoms in the rabbit. When given, however, in sufficient quantity it is certainly capable of disturbing the whole economy, although its exact physiological action has not been worked out. Dr. Isaac Ott has found that when in large dose it produces, in the frog, paralysis of both the motor and sensory functions of the spinal cord, with death from diastolic arrest of the heart; in rabbits, quietude, partial paraplegia, and cyanosis, with acceleration of the respiratory movement and depression of temperature and of the arterial pressure. In the research of Drs. David Cerna and William S. Carter it was noticed that the influence of the drug upon the circulation is exceedingly feeble, so that enormous amounts were required to depress the arterial pressure. The fall of the arterial pressure occurred in curarized animals and also in those in which the spinal cord in the pneumogastric had been previously cut; so that it must be concluded that phenocoll, when in sufficient amount, is a cardiac depressant. It does not seem to have been determined whether the small dose of phenocoll has or has not any stimulant cardiac action. The pulse was found by Cerna and Carter to be primarily decreased by inhibitory stimulation, then increased by inhibitory paralysis, and finally diminished by direct action upon the heart.

The same investigators affirm that phenocoll has no action upon the blood, but the correctness of this seems to be challenged by the cyanosis which has been noted both in man and in rabbits. In experiments made upon animals with fever, Cerna and Carter found that the fall of temperature produced by phenocoll is due to an enormous reduction of heat-production, heat-dissipation not being practically altered. As the result of some evidently not very elaborate chemical studies, Dr. P. Balzer (*Therap. Monatsh.*, 1892) states that phenocoll very distinctly increases the nitrogenous elimination: the correctness of this is very doubtful.

Phenocoll is rapidly absorbed and almost as rapidly eliminated. According to Cohnheim, it may be detected in the urine from one to nine hours after its ingestion. It is probably in part oxidized in the system, since the urine after its free administration becomes of a dark, reddish-brown color. It is possible, however, that the color is due to indican and biliary substances, both of which have been found in the urine.

THERAPEUTICS.—In 1891, Drs. Hertel and Herzog stated that phenocoll rarely, if ever, produces gastro-intestinal irritation or other disagreeable symptoms, that its antipyretic action is quick and never accompanied by any depression, and that the free sweating which is apt to occur with it may be readily prevented by minute doses of atropine (*Deutsch. Med. Wochensh.*, 1891). Both Hertel and Herzog claim that phenocoll is a valuable remedy in *acute and chronic rheuma-*

tism. The first reports regarding the antipyretic action of the drug have received wide confirmation, and it would seem that phenocoll is one of the safest, promptest, and most efficient members of its class. On the other hand, there has been much statement that in rheumatism and as an analgesic in ataxic or other nerve pains it is inferior to the older remedies. These results may, however, have been due to a too timid use of the phenocoll, as it is affirmed by some clinicians that five grammes or seventy-seven grains of it are usually required to effect result in rheumatism, whilst most writers give the dose as much smaller than this. In rare instances it produces vomiting, but I have met with no cases of human poisoning by it. The ordinary dose may be set down as twelve to fifteen grains, in solution or capsule.

THALLIN, or *Parachinanisols*, occurs in the forms of thallin sulphate and thallin tartrate,—each a yellowish-white crystalline powder, with an odor somewhat resembling that of the coumarin bean, and a saline, bitterish, aromatic taste. The sulphate is soluble in seven parts of cold water, the tartrate in ten parts of cold water. Physiologically and therapeutically the preparations are equivalent. Thallin is certainly a powerful antipyretic. According to the researches of N. Tschistowitsch (*Centralbl. f. Med. Wissensch.*, 1885, xxiii. 930), in the normal warm-blooded animal after the ingestion of thallin the bodily temperature sometimes, but not always, falls, while in the fevered animal the fall of temperature is almost invariably pronounced, the antipyretic influence lasting two to six hours, and not being accompanied with any marked depression of blood-pressure unless the dose has been unnecessarily large, when the pulse becomes slower and the pressure sinks. The fall of pressure is said to be partly the result of a vaso-motor paralysis, partly the result of cardiac depression. According to A. Robin (*Bull. Acad. d. Méd.*, xxii., 1889), thallin lessens the destruction of albuminoid matters in the body, diminishes the excretion of uric acid. It has little effect upon intestinal fermentation, and especially attacks the red blood-corpuscles.

To man thallin has been given in doses of from four to eight grains for the relief of fever. It produces usually in half an hour to an hour a fall of temperature, accompanied with excessive sweating, and not rarely with an erythematous or cyanotic discoloration of the skin of the face and extremities. In many cases there have been violent chills, lasting from a few moments to several hours, usually preceding the rise of temperature after the fall. Vomiting is sometimes produced, and very commonly there is diarrhœa, which may be severe. Several observers have also noticed albuminuria (see *Wien. Med. Wochenschrift*, 1887). According to the experiments of Peter J. Martin (*Therap. Gaz.*, May, 1887), the fall of temperature is chiefly due to increased dissipation of heat, although in some of his cases heat-production was also decreased. Professor E. Kreis has discovered that a solution of four to

four and a half per cent. of sulphate of thallin is capable of destroying microbes, and Professor Goll, acting upon these suggestions, found that injections of two- to two-and-a-half-per-cent. solutions of thallin repeated three or four times a day, and aided by the internal administration of the drug in doses of three grains every three hours, have remarkable power in arresting *gonorrhœa*. In *gleet* the irrigation of the urethra with a one- to one-and-a-half-per-cent. solution of thallin produced excellent results.

KAIRIN is a grayish-yellow crystalline powder, of a bitter taste, easily soluble in water and in alcohol. When taken internally in doses of from five to ten grains repeated every three or four hours, it produces in a short time a copious diaphoresis, accompanied with excessive dilatation of the cutaneous vessels and a reduction in frequency of the pulse and respiration. It is said to cause dangerous cardiac depression by a direct influence on the cardiac muscle, and to have also a very decided influence upon the red blood-corpuscles, producing a peculiar lividity and general cyanosis, with threatening collapse. The reports in regard to it have been so unfavorable that it has not been used to any considerable extent in practical medicine. It has no advantages over antipyrin and antifebrin, and appears to be more dangerous.

CLASS II.—LOCAL REMEDIES.

FAMILY I.—STOMACHICS.

THERE are various substances which have the power of so affecting the gastro-intestinal mucous membrane as to increase the functional activity of the various glands and thereby aid digestion. Certain of these substances are of vegetable origin and of a bitter taste, and, while affecting markedly the gastro-mucous membrane as stimulants, have little or no influence upon the general system. These are the so-called *simple bitters*, which in previous editions of this book have been considered under the general heading of *tonics*. Although simple bitters may, by increasing the amount of food taken, affect the general nutrition of the body, it is evident that they are distinct in their action from substances like iron, which more or less directly influence the general tissues of the organism. They are essentially locally-acting drugs. Probably all bitter vegetable substances are stimulants to the gastro-mucous membrane, but in many of them, as in morphine and strychnine, such power is completely overshadowed by other inherent properties. Some of these active bitter vegetable substances are indeed employed on account of their influence upon the alimentary tract, notably quinine and strychnine, but in others of them, like morphine, the local is entirely swallowed up in the general influence. By virtue of their stimulant power the simple bitters produce, when in overdoses, nausea, and may even cause active irritation of the gastro-mucous membrane. They have also some tendency to act upon the bowels. They are essentially irritant, and are contra-indicated by inflammation or over-sensitiveness of the alimentary mucous membrane. They are especially indicated by loss of appetite, when such loss of appetite is the outcome of a depressed condition of the stomach, but when it is the result of gastro-inflammation they will do harm. A second class of stomachics are the so-called *aromatics*, which depend for their activity upon the presence of a volatile oil. They differ from the simple bitters in being more powerful but less permanent as local stimulants. (See page 718.) A third class of drugs contain both volatile oil and bitter principle, and unite the properties of the aromatics with those of the simple bitters. These are the so-called *aromatic bitters*.

SIMPLE BITTERS.

QUASSIA. U.S.

The wood of *Pieræna excelsa*, a large tree, native of Jamaica. This wood is light both in density and color, somewhat resembling that of the tulip-tree, but distinguished by its intensely bitter taste. It is kept in the shops in billets and in raspings. The active principle of it appears to be *Quassin*, an intensely bitter, neutral, crystalline principle discovered by Winckler (*Repert. f. Pharmacie*, Bd. liv. p. 85, Bd. lv. p. 85). *Simaruba*, the bark of the root of *Simaruba officinalis*, also contains quassin, and may be substituted for quassia.

PHYSIOLOGICAL ACTION.—Quassin is said in large doses to be actively poisonous to insects, and even to mammals (Stillé's *Therapeutics*, i. 472; Husemann, *Die Pflanzenstoffe*, p. 718); but I have met with no detailed study of its action except that of I. Hoppe, who experimented upon frogs (*Deutsche Klinik*, xi., 1859). In doses of one grain it usually produced death in a short time. The symptoms were great weakness, with, in most cases, convulsions and sometimes convulsive tremblings, failure of respiration, and finally cessation of cardiac action. The functional activity of the nerve-trunks was much impaired, that of the muscles to a less extent. Locally, quassin appeared to act as an irritant as well as a powerful poison to both nervous and muscular tissues. Dr. Campardon found that in doses of five milligrammes of the pure crystalline form, or five centigrammes of the commercial amorphous variety, quassin acts upon man as a powerful bitter tonic, notably increasing the secretion of bile and of the urine, and causing some looseness of the bowels and stimulation of the bladder. Fifteen milligrammes of the crystalline quassin caused violent frontal headache, burning pains in the œsophagus and throat, nausea, vomiting, vertigo, excessive nervous restlessness, diarrhœa, and very frequent micturition, but diminished renal secretion (*Bull. Thérap.*, clii. 410).

THERAPEUTICS.—Quassia is probably the most active of all the simple bitters, and may be used whenever such remedies are indicated. In cases of *seat-worms* in children, a strong infusion of quassia (3ii to Oj) affords a most harmless and efficient injection. Its exhibition should be preceded by an enema of simple water, after a stool, so as thoroughly to wash out the rectum and allow access to every fold of the rectal mucous membrane. The official preparations are a *tincture* (*Tinctura Quassia*—10 per cent., U.S.), dose, twenty drops to a teaspoonful, a very excellent watery *extract* (*Extractum Quassia*, U.S.), which may be given in pills containing from one to three grains; and a *fluid extract* (*Extractum Quassia Fluidum*), dose, five to ten drops.

GENTIANA—GENTIAN. U.S.

The root of *Gentiana lutea*, or the yellow gentian of the Alps. This root occurs in the shops either in pieces of various sizes and shapes but

generally several inches in length, or else in transverse slices. The texture is spongy, the odor faint but peculiar, and the taste bitter. It contains *gentisic acid*, which was discovered by Leconte and is tasteless and physiologically inert. The active principle is probably the *gentiopikrin* of Kromayer, a neutral, crystalline substance, of an intensely bitter taste.

THERAPEUTICS.—Gentian is one of the most efficient of the simple bitters, and may be used whenever such a remedy is indicated. It is never given in substance, but in one of its preparations. These are the *compound tincture* (*Tinctura Gentianæ Composita*—10 per cent., U.S.), which contains gentian, bitter orange peel, and cardamom—dose, one fluidrachm to half a fluidounce; the *watery extract* (*Extractum Gentianæ*, U.S.), dose, two to four grains; and the *fluid extract* (*Extractum Gentianæ Fluidum*, U.S.), dose, ten minima to half a fluidrachm. The *compound infusion*, formerly officinal, was a valuable preparation, containing some alcohol, and much used in doses of one to two fluidounces.

NECTANDRA.

Bebeeru Bark is the bark of *Nectandra Rodiei*, a large tree which grows in Guiana and the neighboring parts of South America and is used in ship-building under the name of "green-heart." It occurs in large flat pieces, and contains an alkaloid which was discovered by Dr. MacLagan, of Edinburgh. According to the researches of Walz (*N. Jahrb. Pharm.*, 1861, xii. 302) and of Flückiger (*Ibid.*, 1869), this alkaloid is identical not only with *Buxine*, obtained by Fauné in 1830 from *Buxus sempervirens*, but also with *Pelosine*, discovered by Wiggers in *Pareira brava*. *Bebeerine*, or, as it should be called, *buxine*, is whitish, amorphous, inodorous, very bitter, very slightly soluble in water, freely so in ether and alcohol, and forms uncrystallizable salts. Dr. MacLagan found a second alkaloid, *Sipeerine*, in *bebeeru bark*, but it is probably only altered *bebeerine*.

PHYSIOLOGICAL ACTION.—Our knowledge of the influence of *bebeerine* upon the system is exceedingly incomplete. Albers (*Virchow's Archiv*, Bd. xxiv.) found that three grains introduced beneath the skin of a large frog produced death in six and a half hours. There was first a period of quiet with accelerated breathing, then tonic and clonic general convulsions, seemingly associated with muscular weakness, but with no increase of the reflex activity. Professor Binz (*Virchow's Archiv*, Bd. xlvi. p. 130) has determined that *bebeerine* exerts some destructive influence over infusorial forms of life, but that it is in this respect not nearly so powerful as the *cinchona* alkaloids.

THERAPEUTICS.—*Bebeerine* was originally proposed by Dr. MacLagan as a substitute for quinine in *malarial diseases*, and has been quite extensively tried. It appears to possess some antiperiodic powers; but they very probably are not superior to those of the more powerful simple bitters, and are certainly very inferior to those of quinia, so that *bebeerine*

is at present very seldom, if ever, used. The *sulphate* may be given in acidulated solution in doses of from two to five grains.

CALUMBA—COLUMBO. U.S.

The root of *Jateorhiza palmata*, a climbing vine of Mozambique. It occurs in the shops in transverse disk-like slices, oval or circular in outline, one or two inches in diameter, of a spongy texture, having a yellowish surface, a very bitter taste, and a slightly aromatic odor. It contains a great deal of starch, besides berberine, and, it is said, in lesser amount, *columbin*, a bitter neutral principle crystallizing in rhomboid prisms or needles. Dr. F. Roux (*Comptes-Rendus Soc. Biolog.*, 1884, i. 33) has found that columbin given to pigeons in doses of ten centigrammes produces death, preceded by failure of the appetite, marked signs of gastro-intestinal irritation, and jaundice.

THERAPEUTICS.—A bitter, slightly aromatic tonic, useful as a stomachic in cases in which a simple bitter is indicated. It is not used in substance. Its preparations are—a *tincture* (*Tinctura Calumbæ*—10 per cent., U.S.), dose, one to two fluidrachms; and a *fluid extract* (*Extractum Calumbæ Fluidum*, U.S.), dose, fifteen minims to half a fluidrachm.

EUPATORIUM—THOROUGHWORT. U.S.

The herbal parts, gathered after flowering, of the indigenous *Eupatorium perfoliatum*, a tall, coarse composite, recognizable by its perfoliate leaves, through whose centre grow the stems and branches. This drug given in cold infusion (ʒi to Oj—dose, fʒi-ii) is an efficient but disagreeable bitter tonic. Its chief employment is as a sudorific. The hot infusion when taken freely (five to six ounces), the patient being well covered in bed, produces free sweating, and has been very largely used in "general colds," *muscular rheumatism*, etc., for this purpose. The only objection to the remedy is its disagreeable taste. In the dose of a pint the infusion has been employed as an emetic. The *fluid extract* (*Extractum Eupatorii Fluidum*, U.S.) may be used in doses of a fluidrachm to a fluidounce.

CHIRATA, U.S., the herb and root of *Swertia chirata*, a plant growing in the northern part of India, is one of the best of the simple bitters, and is believed by some to exert a peculiar influence over the liver. Whenever a simple bitter is indicated, this drug may be employed, especially if a cholagogue action be desired. The *solid extract* is an excellent preparation in doses of one to two grains; the *fluid extract* (*Extractum Chiratæ Fluidum*, U.S.) may be given in doses of five to ten minims; and the *tincture* (*Tinctura Chiratæ*—10 per cent., U.S.) in doses of a fluidrachm.

PRUNUS VIRGINIANA—WILD CHERRY. U.S.

Wild cherry bark is the product of *Prunus* (*Cerasus*) *serotina* or wild cherry tree, not of *Prunus Virginiana* or choke-cherry, whose

name it bears. It occurs in pieces of various sizes, usually without epidermis. The color is a reddish cinnamon; the taste slightly astringent, bitter, and peculiar, resembling that of peach-leaves. It contains tannic acid, bitter extractive, amygdalin, and emulsin. *Amygdalin* is a nitrogenous, crystallizable, odorless glucoside, of a slightly bitter taste. It is soluble in water and alcohol, but not in ether. *Emulsin* is an albuminous principle, which is soluble in water, and, like other forms of albumen, is coagulated by heat, alcohol, acids, etc. When amygdalin in watery solution is brought in contact with emulsin, it is decomposed, forming prussic and formic acids and a colorless, thin, volatile oil, which, when pure, has a peculiar agreeable odor and a burning taste. According to Liebig and Wohler (*Ann. Chem. Pharm.*, xxii. 1), seventeen grains of amygdalin yield one of hydrocyanic acid: therefore, if thirty-four grains of amygdalin be mixed with sixty-six grains of an emulsion of sweet almonds, a two-per-cent. (by weight) solution of hydrocyanic acid will be formed.

PHYSIOLOGICAL ACTION.—Amygdalin administered by itself is nearly, if not quite, without effect upon the organism. Widtmann and Denk (Husemann, *Die Pflanzenstoffe*, p. 688) took as much as sixty grains of it without inducing any effect, and their results have been confirmed by Reil and others. Lohmann, it is true (*Ibid.*), found that at times fifteen grains of it by the mouth were sufficient to cause death in the rabbit; but Kolliker and Müller have shown that this was owing to its being converted into prussic acid by the emulsin contained in the green herbage in the stomach of the rabbit.

THERAPEUTICS.—In wild cherry bark properly administered there are three active ingredients,—tannic acid, bitter extractive, and prussic acid; and to their combined action the general effect is due. As the tannic acid is in small quantity, its influence is not marked; but probably some of the reputation which the remedy formerly enjoyed as being useful in the night-sweats of phthisis was due to it. The amount of prussic acid in *Prunus Virginiana* is too small to have any perceptible effect, and I have never been able to detect any influence produced by wild cherry bark other than that of a feeble astringent and tonic. It has been very largely used in *phthisis*, and has been supposed not only to act as a tonic and astringent, but also to exert a calumative influence on the nervous system.

The *infusion* (*Infusum Pruni Virginianæ*—4 per cent., U.S.) is useful as an adjuvant to other tonics, especially sulphuric acid, in *debility* with a tendency to night-sweats during convalescence from acute disease. The dose is one to two wineglassfuls. On account of its pleasant taste and its traditional reputation, the *syrup* (*Syrupus Pruni Virginianæ*—15 per cent., U.S.) is often employed as the basis of cough-mixtures. The *fluid extract* (*Extractum Pruni Virginianæ Fluidum*, U.S.) may be given in doses of from half a fluidrachm to a drachm.

AROMATICS.

The aromatic oils are essentially local irritants, causing when taken into the mouth intense burning pain, and, when confined upon the skin, rubefaction, blistering, and finally, if the contact be very prolonged, more destructive changes. Internally, taken in very large doses, they cause burning pain in the stomach, increased activity of the circulation, and a species of intoxication. In sufficiently large quantities they are irritant narcotic poisons. When administered in therapeutic doses they act almost exclusively upon the alimentary canal. As compared with that of the simple bitters, their influence is more powerful and more transient. They do not permanently increase the digestive power, but simply increase action for the time being. They are employed chiefly—to give pungency to bitter tonics; as *carminatives*, to stimulate the intestines to contract upon and expel flatus; to prevent the griping of purgatives; to disguise the taste of medicines, and to render nauseating drugs acceptable to the stomach; and to act as condiments and aid in the digestion of the food.

Injected into the circulation, most volatile oils lower the blood-pressure by depressing the heart's action, and even in comparatively small doses may cause immediate diastolic arrest. In this respect oil of cloves is one of the most powerful. Their cardiac action is undoubtedly direct and upon the heart itself: other muscular structures would seem to be similarly affected, as H. Kobert has found that the oil of mace directly lowers muscular excitability (*Arch. f. Exper. Path. u. Pharm.*, xv. 22).

Some of the tonic drugs containing a volatile oil also have in them a bitter principle which modifies their action. Such drugs may be known as *aromatic bitters*; as bitters they are less powerful than such drugs as quassia, and are especially indicated where the stomach is delicate and easily nauseated.

Inflammation of the stomach or bowels is the chief contra-indication to the use of aromatics. Unlike the simple bitters, they are often very useful in *diarrhœa* of nervous irritability or of relaxation, when no decided inflammation exists.

There is one property which is probably common to the aromatic oils, and which may therefore be mentioned here with propriety,—viz., the power of producing local anaesthesia. In China the oil of peppermint has long been used locally in neuralgia; and my own experience with our native oil is in accord with that of Dr. A. Wright (*Lond. Lancet*, 1874, ii.; see, also, *Gaz. Méd.*, 1874) in finding it efficient in neuralgia and subacute rheumatism. A rag soaked with it should be laid upon the part, and, when the burning is no longer endurable, cosmoline applied. The power of oil of cloves in benumbing sensitive dentine or exposed nerve-pulp is well known. (See MENTHOL, p. 669.)

CINNAMOMUM.—The U.S. Pharmacopœia recognizes as the barks of undetermined species of the genus Cinnamon, *CINNAMOMUM CASSIA*, *Cassia Bark*, *Chinese Cinnamon*, and the *CINNAMOMUM SAIGONICUM*, or *Saigon Cinnamon*, which comes from Cochin China; it also recognizes *CINNAMOMUM ZEYLANICUM*, or *Ceylon Cinnamon*, the bark of the *Cinnamomum zeylanicum*. Of these barks the Ceylon is considered the finest and the Cassia the poorest in quality. They all contain tannic acid and a yellowish volatile oil (*Oleum Cinnamomi*, U.S.), which on account of its great fragrance and very pleasant taste is largely used, in doses of from one to three drops, as an adjuvant, or to disguise the flavor of less agreeable drugs. *Cinnamon water* (*Aqua Cinnamomi*—oil 0.2 per cent., U.S.) is used solely as a vehicle. The *spirit of cinnamon* (*Spiritus Cinnamomi*—oil 10 per cent., U.S.) is administered in doses of half a fluidrachm; the *tincture* (*Tinctura Cinnamomi*—Ceylon Cinnamon—10 per cent., U.S.) in doses of one to two fluidrachms. *Pulvis Aromaticus*, U.S.—*Aromatic Powder* (cinnamon, ginger, cardamom, nutmegs) is an elegant carminative in doses of from ten to twenty grains.

CARYOPHYLLUS, U.S.—*Cloves* are the unexpanded flowers of *Eugenia aromatica*, a tree growing in the Molucca Islands. This aromatic, largely used as a spice, contains an exceedingly pungent volatile oil, officinal as *Oleum Caryophylli*. This is a yellowish oil, becoming dark by age, which, besides being used as a carminative and an aromatic, is often employed to benumb sensitive dentine, or even exposed pulp, in *caries* of the teeth. Dropped on a piece of cotton and placed in the cavity, it will frequently cure *toothache*. Dose, one to two drops. The *infusion*, or *clove tea* (*Infusum Caryophylli*—3ii to Oj), is made with boiling water; the dose is a wineglassful.

MYRISTICA, U.S.—*Nutmeg* is the kernel of the fruit of *Myristica fragrans*, a tree inhabiting the Molucca Islands. The nutmeg contains both a fixed and a volatile oil. *Mace* (*Macis*, U.S.P.) is the *arillus* or outer imperfect supernumerary coating of the seed. It contains a volatile oil identical with that of the nutmeg. The nutmeg is possessed of narcotic power, and it is said that one or two when taken will produce a dreamy, half-unconscious condition. In a boy aged about eight years fatally poisoned by an unknown quantity of nutmeg, there was complete coma, with suppression of urine and respiratory paralysis (*N. Y. Med. Record*, Nov. 1886). Parts of five nutmegs produced in a boy dizziness, followed by quiet unconsciousness, great muscular relaxation, dilated pupils, and slow pulse, respiration and temperature remaining normal, and recovery occurring in thirty hours (*A. Sawyer, New York Med. Journ.*, vol. i., 1889). In my own experiments, and in those of Cadeac and Meunier (*Journ. Méd. Vet.*, Lyon, 1890), the intravenous injection of the volatile oil produced in the lower animals a marked intoxication, with loss of co-ordination, tremors, and, when

the dose had been sufficiently large, profound narcosis, with abolition of all reflexes, and, finally, death from paralysis of the respiratory centres. Upon the circulation the action of the oil is comparatively feeble. The French observers state that in a certain stage of the poisoning there is great increase of the amount and frequency of the respiratory movements. The dose of the volatile oil (*Oleum Myristica*, U.S.) is from two to five drops.

PIMENTA, U.S.—*Pimenta*, or *Allspice*, is the unripe berries of *Pimenta officinalis*, a tree, native of the West Indies. It contains a green fixed oil and a volatile oil (*Oleum Pimentæ*, U.S.), the dose of which is two to five drops.

CARDAMOMUM, U.S.—*Cardamoms* are the fruit of *Elettaria repens*, which grows in the East Indies. They consist of tough, seemingly fibrous, generally more or less triangular capsules, containing a number of small, hard, very aromatic seeds. The capsule is itself dry and tasteless. In commerce cardamoms are divided into three varieties, according to their length. According to Trommsdorff, the seeds contain, besides 10.4 per cent. of fixed oil, 4.6 per cent. of a colorless, highly aromatic, volatile oil. Cardamom is a very grateful aromatic, much less stimulating and heating than most of the other drugs of its class. The dose of the *tincture* (*Tinctura Cardamomi*—10 per cent., U.S.) is one fluidrachm. The *compound tincture* (*Tinctura Cardamomi Composita*—2 per cent., U.S.) is a very elegant addition to, or vehicle for, tonic medicines; dose, one to two fluidrachms.

ZINGIBER, U.S.—*Ginger* is the dried rhizome or root-stock of *Zingiber officinale*, growing in the East and West Indies. *Green Ginger* is the *fresh* rhizome. *Black Ginger* is the root-stock dried with the epidermis on; *White* or *Jamaica Ginger* is the same, deprived of its epidermis. The fresher ginger is, the greater is its power, and by time and exposure it becomes completely inert. Its active principles are a soft, acrid, aromatic resin, and a yellow, volatile oil. Ginger is much used in domestic medicine as a stimulant carminative in *colic*; given in hot water, it is also used as a sudorific and stimulant in the pain due to *suddenly-suppressed menstruation*. It is often added with advantage to other remedies in *dyspepsia*. The *syrup* (*Syrupus Zingiberis*—3 per cent., U.S.) is used only as a cordial drink or vehicle, in doses of from half a fluidounce to a fluidounce. The *tincture*, often called *Essence of Ginger* (*Tinctura Zingiberis*—20 per cent., U.S.), is the most commonly employed preparation; the dose is half a teaspoonful to a teaspoonful. The dose of the *fluid extract* (*Extractum Zingiberis Fluidum*, U.S.) is five to ten drops. The *oleoresin* (*Oleoresina Zingiberis*, U.S.) is used as a stimulant addition to tonic pills; the dose is from half a minim to two minims.

PIPER, U.S.—*Black Pepper* is the unripe berries of *Piper nigrum*, a woody vine-like plant growing in the East Indies. *White Pepper* is the ripe berries stripped of their skin and dried. It is much less pungent than the black pepper. The active principles of black pepper are a soft, acrid resin, a pungent, fiery, volatile oil, and piperin.

In 1819, Oersted discovered *Piperin* (*Piperinum*, U.S.), which crystallizes in colorless, glistening, four-sided, truncated prisms, of a neutral reaction, but capable of combining with acids to form salts. When pure it is tasteless; but very commonly it has a burning taste, due to the presence of some of the volatile oil of pepper. The possession of very active antiperiodic properties has been claimed for piperin,* and it was for a time employed in *intermittent fever*; but it has fallen into complete disuse. The dose as an antiperiodic is four grains, repeated once or twice during the interval between the paroxysms. According to the observations of Professor H. Kronecker and of Herr Fliess, piperin in the frog paralyzes the peripheral ends of the sensory nerves (*Archiv für Physiologie*, 1882, p. 111). In the rabbit its action upon the sensory nerves is much less marked. The respiratory and pulse rates are greatly accelerated, and death is finally caused by cardiac arrest (*Ibid.*, 1884). MM. Oechsner de Coninck and Pinet (*Comptes-Rendus Soc. Biolog.*, Oct. 17, 1885, May 1, 1886, Oct. 30, 1886) have found that piperin, when brought in direct contact with the nerve, paralyzes both motor and sensory fibres, and that there is no difference in the action of synthetical artificial piperin and the natural principle. Pepper is very largely used as a condiment; but, as its taste is more hot than aromatic, it is rarely given internally in medicine except as an addition to simple bitters or to antiperiodics, generally in the form of the *oleo-resin* (*Oleo-resina Piperis*, U.S.), the dose of which is one-half to one grain. In atonic *dyspepsia* the latter preparation is an excellent adjuvant to tonic pills. Dr. Schiffer is said (Fliess) to have used piperin successfully in a case of *vaginismus*, by injecting 0.3 grain hypodermically near the vaginal entrance. In using piperin by hypodermic injections it is of the utmost importance that it be free from the oil of pepper.

CAPSICUM. U.S.—The U.S. Pharmacopœia now recognizes only the small, less than an inch long, very fiery fruit of *Capsicum fastigiatum*, the *African Pepper*, or *Chillies*. The large, bright red, conical or ovate, comparatively mild peppers of the market are from *C. annum*; they are sometimes known as *West India peppers*. *Capsicum* contains as its active principle an exceedingly acrid oleoresin. The name of *Capsicin* has been applied by different observers to the oil, to the resin, and to their combination, but should, I think, be dropped, as having no definite meaning.

Capsicum is a very powerful local irritant, its oleoresin when applied

* For a discussion of the subject, see Husemann, *Die Pflanzenstoffe*, p. 492.

to the skin producing in a very few minutes intense pain and redness, and finally destroying the cuticle. In the alimentary canal it acts in a similar manner: thus, moderate doses produce merely a pleasant feeling of warmth in the stomach, while overdoses may cause gastro-intestinal inflammation, with severe pain, as well as vomiting and purging. The chief use of *Cayenne Pepper* is as a condiment; yet it is often added with advantage to tonic pills to increase their immediate action on the stomach. When there is habitual feeble digestion, with flatulence, its free use or food may do good. In *adynamic disease*, especially as occurring among *drunkards*, capsicum is often very useful by stimulating the stomach up to the point of digesting food. *Locally*, either as the diluted tincture in a gargle, or applied in powder or tincture by means of a swab, it is useful in *severe tonsillitis*, especially in that accompanying scarlet fever.

ADMINISTRATION.—The dose of capsicum is four to five grains in pill form; of the *oleoresin* (*Oleoresina Capsici*, U.S.), which is to be preferred on account of its lesser bulk, from one-quarter to one-half a grain. The *tincture* (*Tinctura Capsici*—5 per cent., U.S.) is employed locally, and is sometimes administered in one-half to one fluidrachm doses to drunkards. The *fluid extract* (*Extractum Capsici Fluidum*, U.S.) is given in one-half to one minim doses.

OLEUM CAJUPUTI, U.S.—The *Oil of Cajuput* is obtained from the leaves of *Melaleuca leucadendron*, a tree growing in the Molucca Islands. This volatile oil is of a green color, a peculiar fragrant odor, and a burning, camphoraceous taste. It is not very irritating to the skin, but is exceedingly destructive to low forms of life, and consequently has been used as a *parasiticide* externally, and even internally against the *Ascarides*. I have never used it except as a carminative and aromatic stimulant in cases of *intestinal pain* and *spasm*, and in *serous diarrhœa*. When employed in these affections in combination with chloroform, camphor, and opium, it is very efficient. As a counter-irritant, it has been used in *rheumatism*; as a stimulant to the skin, in *psoriasis*, *acne rosacea*, and *pityriasis*. The dose internally is from ten to fifteen drops.

OLEUM SASSAFRAS, U.S.—The *Oil of Sassafras* is enormously used in the arts on account of its cheapness and pleasant flavor. It is capable of producing very marked narcotic poisoning (case, *Trans. Med.-Chir. Faculty Maryland*, 1884, 288), and is said to act upon the lower animals as a convulsant and narcotic. Dr. John Bartlett (*Chicago Med. Journ.*, Dec. 1885) asserts that it is capable of producing uterine contractions, and reports cases of abortion caused by it.

AURANTII AMARI CORTEX.—BITTER ORANGE PEEL, U.S.—The *fluid extract* (*Extractum Aurantii Amari Fluidum*, U.S.) and the *tincture*

(*Tinctura Aurantii Amari*—20 per cent., U.S.) may be given respectively in doses of twenty minims and a fluidrachm. AURANTII DULCIS CORTEX—SWEET ORANGE PEEL, U.S.—Of the *syrup* (*Syrupus Aurantii*—5 per cent., U.S.) the dose is a dessertspoonful, of the *tincture* (*Tinctura Aurantii Dulcis*—20 per cent., U.S.) a tablespoonful. The orange peels are themselves scarcely medicinal, but are official as affording preparations much used as vehicles. LIMONIS CORTEX, U.S., or *Lemon Peel* (*Spiritus Limonis*—5 per cent., U.S.), is also used for flavoring purposes.

AURANTII FLORES.—The flowers of the orange are official for the preparation of *Orange Flower Water*,—*Aqua Aurantii Florum*, U.S.,—which is used as an elegant vehicle, free from medicinal properties.

The fruits of the following umbelliferous plants, *Feniculum capillaceum*, *Carum carui*, *Coriandrum sativum*, *Pimpinella anisum*, are official under the respective names of *Feniculum* (*Fennel*), *Carum* (*Caraway*), *Coriandrum* (*Coriander*), *Anisum* (*Anise*). They all depend for their virtues upon volatile oils which are official. The oil of anise of commerce is chiefly the product of a Chinese tree, the *Illicium anisatum*, or *Star Anise*, from whose five- to ten-rayed capsular fruit it is obtained by distillation. The *Aqua Feniculi*, 0.2 per cent., and *Spiritus Anisi*, 10 per cent., are official. All of these fruits and their preparations may be used as carminatives and stomachics.

The herbal portions of the following mints are official: *Salvia officinalis*, *Mentha piperita*, *Mentha viridis*, *Melissa officinalis*. They are respectively known as *Sage* (*Salvia*), *Peppermint* (*Mentha piperita*), *Spearmint* (*Mentha viridis*), and *Balm* (*Melissa*). The important U.S. preparations of them are as follows: *Aqua Mentha Piperita*—*Peppermint Water*, and *Aqua Mentha Viridis*—*Spearmint Water*, both very frequently used as vehicles. *Spiritus Mentha Viridis* and *Spiritus Mentha Piperita*—*Essence of Spearmint* and *Essence of Peppermint*, used as carminatives, in doses of from ten to twenty drops. The oils of lavender,* peppermint, and spearmint are also official, and may be used in doses of from three to ten drops as carminatives. *Spiritus Lavandulae* (*Spirit of Lavender*), a very elegant and agreeable stomachic and cor-

* MM. Mascia and Braylant have studied to some extent the physiological action of the oils of lavender, rosemary, marjoram, and aspic (*Lavandula spica* L.) (*Bull. Acad. Roy. Méd. de Bruxelles*, 1879, 558; see, also, *Schmidt's Jahrb.*, clxxx. 123, and Cadec and Meunier, *Compt.-Rend. Soc. Biolog.*, 1889, and *Lyon Méd.*, 1889). In frogs they caused generally paralysis, with loss of reflex activity, the muscles being intact, and the sensory nervous apparatus being affected before the motor. Upon the higher animals a similar effect was produced, except that oil of rosemary caused epileptiform convulsions. Oil of Peppermint (*M. piperita*) has been studied by S. D. Markuson (*Inaug. Diss.*, Halle, 1877; *Schmidt's Jahrb.*, clxxx. 122), who finds that while very small doses increase, larger ones decrease the blood-pressure and lower the bodily temperature.

dial, is made by dissolving oil of lavender flowers in alcohol; dose, a fluidrachm to half a fluidounce. Sage contains tannin.

Water of Rosemary (*Aqua Rosmarini*) has long been believed to have especial influence upon the skin, and in cases of *acne* a lotion composed of a pint of this water and an ounce of the flowers of sulphur is often extremely effective.

The volatile Oil of *Gaultheria* (*Oleum Gaultheriæ*, U.S.) is used for flavoring-purposes. Its physiological and therapeutic properties are entirely different from those of other volatile oils, and will be found fully discussed under the head of SALICYLIC ACID. *Calamus*, the rhizome of *Acorus Calamus*, also contains a volatile oil, and its infusion is sometimes used as a carminative.

AROMATIC BITTERS.

ANTHEMIS. U.S.—CHAMOMILE.

Roman or true Chamomile is the dried flowers of *Anthemis nobilis*, a composite of Europe. They are sometimes single, sometimes double. The single are more aromatic than the double florots. Chamomile contains a bluish or sometimes greenish volatile oil, a bitter principle, and a small amount of tannin. *MATRICARIA*, U.S., or *German Chamomile*, is the flowers of *Matricaria Chamomilla*, which are decidedly smaller than those of the ordinary chamomile, and have a stronger, less agreeable odor and taste. Their volatile oil is very similar to that of chamomile.

THERAPEUTICS.—An excellent stimulant tonic, especially useful in convalescence. The dose of the infusion (*Infusum Anthemidis*—℥ss to Oj) is one to two wineglassfuls before meals.

SERPENTARIA. U.S.—*Virginia snakeroot* is the root of *Aristolochia Serpentaria* and of *A. reticulata*, small herbal plants of the United States. It occurs as fine brittle rootlets attached to a small head, of a camphoraceous odor and taste, and contains a volatile oil, a yellowish-green resin, and a bitter principle. It is an elegant stimulant tonic, especially useful as an adjuvant to more powerful bitters. In overdose it is said to cause vomiting, and even purging. The dose of the tincture (*Tinctura Serpentariæ*—10 per cent., U.S.) is one to two fluidrachms; of the fluid extract (*Extractum Serpentariæ Fluidum*, U.S.), twenty drops.

CASCARILLA, U.S., is the bark of *Croton Eluteria*, a shrub growing in the West Indies. This bark occurs in quills or rolled pieces, and is to be distinguished by its outer grayish and inner deep-chocolate surface, by its spicy bitter taste, and by the pleasant musk-like odor which it gives forth while burning. It contains tannin, volatile oil, and cascarrillin, a neutral, bitter, crystallizable principle. Its therapeutic action is very similar to that of serpentaria. The dose of the infusion (*Infusum Cascarillæ*—℥i to Oj) is a wineglassful.

FAMILY II.—EMETICS.

EMETICS are those drugs which are employed in the practice of medicine for the purpose of producing emesis, or vomiting. The mechanism of vomiting has been so frequently written upon, and has so little connection with the application of emetics, that it is not necessary here to enter upon an elaborate discussion of it.* Suffice it to state that emesis is the result of a very complicated series of actions, in which the chief expulsive force is supplied by the abdominal muscles and the diaphragm,—the stomach, however, participating in the general contraction, and not being, as some have thought, entirely passive. The exact relations and functions of the various nerves concerned are not, I think, fully made out. It has been generally believed that the pneumogastrics were the afferent nerves, and that, although emetics introduced into the circulation after their section vomited, yet irritation of the gastric mucous membrane was not capable of so doing. But Schiff found in his experiments that, even when the nerves were cut in the neck, the introduction of semi-solid food into the stomach gave rise to efforts at vomiting, which were in some cases successful; and MacLagan† has obtained similar results with the sulphates of zinc and copper. Moreover, I have invariably failed to induce vomiting with veratria, even when given immediately after section of the par vagum. Evidently, further investigations are needed.

Vomiting occurs under two provocations, or in two manners. Thus, a mental impression, or a disordered state of the blood, may influence the nerve-centres directly, and emesis, spoken of as *centric*, results; or a peripheral irritation in the stomach itself, or in some other organ, as in the kidneys, may induce vomiting precisely similar in the method of its production to the more ordinary reflex movements; such vomiting is called *reflex* or *excentric*.

Emetics produce their results in both of these methods. Thus, tartar emetic has been believed to affect the centres directly, so as to cause centric vomiting, while sulphate of copper has been believed to irritate the mucous membranes of the stomach, so as to produce reflex

* For a very elaborate general discussion on emetics, see Professor Joseph Carson, *Philæ. Med. Times*, June, 1872; also, Dr. D'Orcellas, *Bull. Thérap.*, lxxxiv. 103.

† *The Action of Medicines in the System*, by F. W. Headland, M.D., Amer. ed., 1939, p 110.

vomiting. Recently much doubt, however has been thrown upon the old views, and it is probable that most emetics have a double influence. Thus, the purging of veratria or of tartar emetic is almost certainly connected with its elimination, and is probably due to a direct action of the circulating poison upon the intestinal mucous epithelium, gland-cells, and peripheral nerves. It seems *a priori* almost a necessity that the vomiting caused by these poisons is produced in the same way as the purging. Dr. D'Ornellas has found that when emetine is injected into the veins of animals the vomiting occurs simultaneously with the elimination of the alkaloid from the gastric mucous membrane, and asserts that Kleimann and Simonowitsch have determined the same thing with antimony.* Further (see page 389), antimony seems to cause vomiting partly by acting upon the centres, partly by irritating the peripheral nerve. Irritant emetics are more prompt than those which chiefly affect the nerve-centres, and act more certainly when the nerve-centres are obtunded, as in narcotic poisoning; they always cause less nausea and general systemic disturbance than do the centric emetics.

Another evident practical fact is, that while centric emetics will act in whatever way they are introduced into the system, the mechanical emetics must be exhibited by the stomach. Thus, apomorphine may be given by hypodermic injection, but mustard must be taken by the mouth. Nevertheless, it is probable that most of the so-called "irritant emetics" act in part by being absorbed, since A. Sacher (*Dorpat Thesis*, 1893) has found that even the sulphate of zinc will, when injected in proper dose into the blood, produce vomiting.

A very curious property of emetics has been pointed out by Dr. E. Harnack (*Archiv f. Exper. Path. u. Pharm.*, iii. 44), who, as the result of an elaborate investigation, affirms as a law that all specific emetic substances destroy, even when in relatively small dose, the excitability of striated muscular fibre. Dr. Harnack seems to establish the general truth of this; but that it is a universal law seems scarcely probable, and the connection between the two properties is very obscure. According to H. Kobert (*Arch. f. Exper. Path. u. Pharm.*, xv. 36), antimony has an effect only when the contact is prolonged.

In regard to the phenomena of vomiting, there are a few points to which it is necessary here to call attention. First of these is the fact that nausea always produces, or is accompanied by, muscular relaxation. Vomiting may take place, as from mustard, without much relaxation; but when it is accompanied by much nausea the whole system is as it were unbenumbed, the skin relaxed and bedewed with perspiration, the pulse soft and feeble, the muscular system limp and incapable of exertion, the

* Copper has been thought to be a purely mechanical emetic, but the experiments of Branton and West (*St. Barikolomew's Hosp. Rep.*, 1876) show that a peptone of copper injected into a vein causes violent vomiting. Those remedies whose irritant powers are great may still well be considered as "mechanical emetics."

mental acts almost suspended. During violent vomiting the blood is driven to the head, so that the whole exterior of the cranium, and probably the interior also, becomes very much congested. The abdominal circulation is very much affected, and the blood is as it were squeezed out of the portal vein and its tributaries. The matters rejected consist of the contents of the stomach, and, in repeated vomiting, also those of the duodenum. The secretion from the gastric mucous membrane is very much enhanced, and without doubt is more or less modified. Bile in ejecta is to be recognized by the green color and the bitter taste, or more infallibly by testing with the proper reagents.

The indications for the use of emetics are as follows:

1. *To unload the stomach.*—For this purpose they are employed in poisoning; in the existence of crude articles of food or indigestible substances in the stomach; or in the presence of acrid, perverted secretion. The symptoms induced by irritating materials in the stomach are various, and sometimes it requires a good deal of tact or experience to recognize their cause. Among them may be mentioned a feeling of weight or load in the stomach, gastric distress, or severe cramp or spasmodic pains, with or without some nausea and retching. In other cases no local manifestations of trouble may be present. Thus, *convulsions* in children are very frequently the result of gastric irritation, and are at once relieved by emptying the stomach. In adults, *apoplectic coma* may offer a similar history. Occasionally *urticaria*, or hives, and not rarely severe *headache*, have a similar origin, and require a similar treatment.

2. *To affect the abdominal viscera and circulation.*—Emetics have been recommended by some in *congestions* of the *spleen*; but evidence is wanting as to their power to affect materially other viscera than the liver.

In *congestion* of the *hepatic* and *portal* circulation, not dependent upon organic cause, and in the condition of digestive derangement known as *biliousness*, they are often of service. In *catarrhal jaundice* they may effect much good by causing dislodgement of the mucus plugging the ducts. They have been employed in cases of *biliary calculi*; but the chances of forcing out the calculus by external violence are probably no greater than those of lethal rupture of the gall-bladder.

3. *To dislodge substances from the respiratory passages.*—For this purpose emetics are sometimes used when foreign bodies have found entrance into the larynx; but it is chiefly in *membranous croup* that the present indication is met with. The emetics chosen for this purpose should be such as act with violence without producing much nausea or systemic disturbance: the mechanical emetics are therefore the best.

4. *To produce muscular relaxation.*—The introduction of *anaesthesia* has rendered the use of emetics to meet this application almost obsolete. Occasionally, however, in *asthmatic* or other *spasmodic affections* of the respiratory organs, emetics are still employed. For this purpose the drugs causing much nausea are preferred. In adults, *lobelia* is the

best; in children, ipecacuanha. Nauseating rather than emetic doses should be employed.

5. *To lessen arterial action and reduce inflammation.*—Almost the sole disease in which advantage can be derived from this use of emetics is *acute bronchitis* in its early stages. In very many cases a "cold on the chest" in its outset may at once be subdued by ipecacuanha, or, better still, tartar emetic: small doses should be given at short intervals, to produce continuous nausea, terminating after a time in vomiting. This method of cure is so disagreeable, although very efficacious, that patients will rarely submit to it, unless, as sometimes in the case of public speakers, relief within a short period of time be a matter of great importance. It should be added that the cure is wrought in these cases not merely by the lessening of arterial action, but also by the induction of free bronchial secretion.

6. *To create a shock to the system.*—Under this head may be included several empirical uses of emetics, in which advantage is gained, but in a method which is not very clear. Thus, in *epileptic attacks*, when the fits have a tendency to recur every few minutes, the unconsciousness persisting, it may be, for hours, emetics will sometimes break up the succession of disordered nervous action. Again, it is said that an *ague-fit* can be set aside by an emetic given just before its expected recurrence.

Contra-indications.—The chief contra-indications to the use of emetics are the existence of congestion of the brain, and of gastric inflammation. Advanced pregnancy, and hernia, while they do not positively contra-indicate the use of emetics, should cause great caution to be practised in their employment.

ADMINISTRATION.—Emetics should, as a general rule, be given in a full dose, so as to avoid unnecessary repetition, and should be administered dissolved in water or in syrup. Their action should be assisted by frequent and copious draughts of tepid water, which also have the advantage of rendering the vomiting less painful. When for any reason protracted nausea is desired, the doses should be small and repeated at short intervals.

Hyperemesis may advantageously be divided into two varieties: first, such as is due to overdoses of depressing centric emetics; second, such as arises from irritation of the stomach, as by mechanical emetics. The treatment of the first of these consists in the enforcement of absolute quiet in the horizontal position, the free use of opium enemata, the application of counter-irritants to the epigastrium, and the use of alcoholic stimulants. The latter should be given in hot water, and should not be too much diluted. I have seen raw brandy arrest at once the most alarming centric emesis, after the failure of other methods. Creosote, chloroform, or chloroform and volatile oils, are sometimes of value in this form of hyperemesis. When excessive vomiting is due to some irritant emetic, the stomach should be thoroughly washed out by large draughts of warm mucilage, opium given by the rectum, a mustard

plaster or blister, or, often better still, leeches, applied to the epigastrium, and no medicine at all be taken into the inflamed viscus. The swallowing of small pieces of ice is sometimes of service. If these remedies fail, the treatment of this form of hyperemesis soon resolves itself into that of gastritis.

VEGETABLE EMETICS.

IPECACUANHA. U.S.

The root of *Cephaelis Ipecacuanha*, a small, shrubby plant, growing in Brazil, where the drug is gathered by the Indians, to be exported in large bales or bags. Ipecacuanha occurs in pieces of two or three lines in thickness, variously bent and contorted, marked on their surface with numerous prominent rings, and composed of an outer, thick, active, hard, and horny cortex, and an inner, light, inert, woody centre. Varieties of ipecacuanha—the *red*, the *gray*, and the *brown*—have been formed from the color of the bark, but the distinction is trivial. The root has very little odor, but the brown powder has a decided and peculiar smell, and in some persons excites sneezing, or even violent asthmatic dyspnoea. The taste is bitter, acrid, and nauseous. The active principle is *Emetine*, an alkaloid first discovered by Pelletier in 1817. The cortex also contains small quantities of ipecacuanhic acid, which is related to tannic acid. Pure *emetine* is a white, uncrystallizable, odorless powder, of a bitter, burning taste, soluble in one thousand parts of water at 50° C. (Lefort), freely soluble in dilute and absolute alcohol, in chloroform and benzole, scarcely so in ether. Its solution in acidulated water, according to Dragendorff, has a decided blue fluorescence. Its salts are, according to Pelletier, uncrystallizable. Concentrated sulphuric acid turns it a dirty brown, nitric acid a yellowish brown. Pure *emetine* is very difficult to prepare, and, according to Mr. Williams (*St. Bartholomew's Hospital Reports*, vol. v.), only two grains of it can be obtained from an ounce of the root. The ordinary impure alkaloid of the shops occurs in brownish-red, transparent, very deliquescent scales, which are very soluble in water.

PHYSIOLOGICAL ACTION.—Locally applied, ipecacuanha is a decided irritant, manifesting its action not only upon mucous membranes and upon denuded surfaces, but even, when used by inunction, producing an eruption upon the sound skin. According to Dr. Dyce Duckworth, this eruption consists at first of small, discrete pustules with a rather large areola; afterwards, if the application be persisted in, of large pustules, followed by severe ulceration. When exhibited in small repeated doses to man, it produces malaise, with nausea, and perhaps an increase of the secretions of the salivary glands and of the mucous membrane of the bronchial tubes and of the stomach. In large amounts it causes vomiting, accompanied by only a moderate amount of nausea but by a decided increase of the secretions mentioned above.

The vomiting, even when very large amounts are taken into the stomach, is not apt to be severe, nor the prostration marked,—no doubt because the excess of the drug is rejected before absorption. After large doses of emetine this mildness of action, in all probability, would not be present: certainly animals are readily killed by the alkaloid. Although ipecacuanha was made known in 1649 by Piso, and although it has been enormously used since its introduction into Europe in 1672, its physiological action is not as yet well made out. That the active principle is absorbed, and that the vomiting is so produced, is shown by the experiments of Orfila (*Toxicologie*, i. 651), and of Drs. Dyce Duckworth, D'Ornellas, and Pecholier, who found that vomiting followed the hypodermic use of emetine in dogs and cats. If it be true, as is affirmed by D'Ornellas, that the emetine produces vomiting much more slowly when thrown into the veins than when given by the stomach, it would seem that the local irritant action of the drug efficiently favors emesis.

According to Dr. D'Ornellas (*Gaz. Méd.*, 1873, p. 537), Merck's commercial emetine in toxic doses (0.02 milligramme) produces in frogs dryness of the skin, swelling of the abdomen, diminution of the circulation and respiration, increased rather than diminished sensibility, muscular feebleness deepening into abolition of voluntary movement, with at first increased and afterwards diminished reflex activity, and finally death from failure of respiration; the heart continuing to beat often for many hours. In mammals the symptoms induced by the poison in large doses are very similar to those just detailed, except that emesis is usually violent, but in some cases it is wanting.

Circulation.—The action of the drug upon the circulation has not as yet been clearly made out. Any action upon the heart-muscle must be a very feeble one, since D'Ornellas states that although the frog's heart is finally arrested in diastole, yet it retains often for many hours its irritability. It has been supposed by some that the drug acts especially upon the vaso-motor system; but evidence of this has not as yet been brought forward. Polichronie, it is true, asserts (*L'Ipecacuanha*, Paris, 1874) that dryness and paleness of the intestinal mucous membrane are very apparent in mammals poisoned with emetine, and Chouppe (*Le Progrès Méd.*, 1874, p. 425) has observed the same thing; but this is an absurdly slight ground for believing that emetine causes vaso-motor spasm. Pecholier found in a single experiment that the drug abated very decidedly the arterial pressure, but Dr. D'Ornellas found that emetine neither depresses nor increases the blood-force; and in a series of elaborate experiments by Dr. Dyce Duckworth the alkaloid failed to influence materially the circulation, at least until very late in the poisoning. The pulse-rate was not constantly affected; sometimes it was apparently lowered, sometimes it remained about the same, and sometimes it was seemingly increased. The effect of an overwhelming dose was, however, marked. In one case immediate suspension of car-

dian action followed injection into the jugular vein; in another dog, in a minute and a half after half a grain of emetine the arterial pressure descended from 135 to 20, and in a moment the animal was dead of cardiac paralysis. Dr. Foulkrod (*Phila. Med. Times*, viii. 554) has noticed a steady fall of arterial pressure produced both before and after section of the cord of all the cardiac nerves. There is no proof that emetine ever causes vaso-motor spasm, while it is certain that toxic doses directly paralyze the heart; therapeutic doses probably have no decided direct effect upon the circulation.

Respiration.—According to D'Ornellas, Pecholier, and Foulkrod, emetine in toxic doses usually kills by arresting the respiration; but in many of Dyce Duckworth's experiments (*St. Bartholomew's Hosp. Rep.*, v., vii.) the death was certainly the result of cardiac paralysis, possibly because the poison was thrown directly into the circulation,—i.e., into the heart.

Nervous and Muscular Systems.—Upon the cerebrum ipecacuanha exerts no perceptible influence; but, as both D'Ornellas (*loc. cit.*, p. 538) and Pecholier (*loc. cit.*, p. 57) have found that after death from emetine in the frog both nerves and muscles retain their susceptibility to feeble galvanic currents, the paralysis which the poison produces is probably spinal. D'Ornellas and Pecholier are in opposition in regard to the action of the alkaloid upon sensibility, the one affirming that it is not, the other that it is, affected.

Temperature.—Pecholier, Dyce Duckworth, and D'Ornellas all state that in emetine-poisoning there is a distinct fall of temperature in the mouth and on the surface of the body, but that in the intestines the temperature either remains stationary or, more commonly, rises; D'Ornellas affirms that it always rises decidedly. This rise is probably, as D'Ornellas believes, local, and due to the action of the poison upon the intestinal tract.

Pulmonic and Digestive Organs.—The post-mortem results obtained in animals poisoned with ipecacuanha are diverse, but affect chiefly either the lungs or the digestive tract. Pecholier, in his earlier experiments, found great paleness of the lungs, with intense hyperæmia of the stomach and the upper half of the intestines, but in some of his later experiments the lungs were profoundly influenced. Dyce Duckworth especially noted intense hyperæmia of the lungs, which were in some places emphysematous, but in other portions collapsed and even affected with true consolidation. The lesions were much less marked in the intestines than in the lungs, which resembled very closely those taken from the bodies of animals killed by section of the vagi. The pulmonic lesions were found to be most intense in the rabbit; the intestinal, in the dog, cat, and guinea-pig. Magendie forty years ago noted the pulmonic lesions of emetine-poisoning, and D'Ornellas has likewise recorded them, but has also seen cases in which ischæmia of the pulmonary tissue was found after death. It is evident that the poison has an

especial action upon both lungs and intestines; but why the pulmonic lesions should so vary is not at present known. The occurrence of changes in the pulmonary tissues is in accord with the results of clinical experience, which teaches most decidedly that ipecacuanha has an action upon the pulmonary mucous membranes. After section of the cervical vagi, Dr. Dyce Duckworth found that emetine failed to cause vomiting.

Clinical experience also shows that ipecac acts upon the digestive tract. Whether given in large or in small doses, it is very apt in man to increase and modify the intestinal secretions. It probably influences the liver, since Pecholier (*Gazette Médicale*, 1862) affirms that in animals killed by it no hepatic glucose can be found. Moreover, great advantage from its use may often be obtained in the condition known as "biliousness." In "bilious dysentery" it will often produce large tarry discharges; and I have seen a change in the color of the stools follow its use in catarrhal jaundice. The mechanical effect of the vomiting induced by it in these cases, however, must not be lost sight of; yet it does not seem to me at all sufficient to account for the results, especially as some observers state that the effects noted are produced even when little or no vomiting occurs. It has been proved by D'Ornuellas and Pecholier that when emetine is introduced into the circulation or into the cellular tissue it escapes with the secretions of the stomach and bowels; so that the changes which are provoked in these organs are evidently connected with the elimination of the drug.

THERAPEUTICS.—The most ordinary use of ipecacuanha is as an emetic. Whenever it is desired to unload the stomach or to act by emesis upon disease, without inducing much prostration, this drug commends itself by its safety and efficiency. In *narcotic poisoning* it is less certain than the "mineral emetics," but, as it produces no irritation of the stomach, can be given more freely than they can, and is constantly used as an adjuvant to them. It is especially useful in the diseases of children, never causing the serious depression which tartar emetic is so apt to produce. When, however, very violent emesis is desired, as in *membranous croup*, other emetics, such as zinc or alum, are to be preferred, on account of the greater force of their action.

In *sick stomach* of nervous origin, such as occurs in *pregnancy*, minute doses of ipecacuanha have so often met with success that there can be no doubt of their value. One drop of the wine in a teaspoonful of water should be given every hour. The use of ipecacuanha as an expectorant will be spoken of under that heading.

One of the most important uses of ipecacuanha is in *acute dysentery*,—all forms of which have been treated with it with asserted advantage. I think, however, its beneficial action is best seen in "*bilious dysentery*" and in "*malignant dysentery*," as is indicated by the fact that its use is most common in tropical climates. In "*sthenic inflammatory dysentery*" it seems to be less available; although even in this it has been strongly

advocated by some. Dr. Chouppe (*Bull. Thérap.*, June, 1874) commends injections of ipecacuanha highly in *choleriform diarrhœa* of children, and in *tuberculous diarrhœa*, and Polichronie not only corroborates him, but also affirms that the same treatment is of great value in *colliquative sweats*. In a very valuable clinical paper (*Atlanta Med. and Surg. Journ.*, 1875) Dr. A. A. Woodhull brings forward very strong evidence of the value of the remedy not only in dysentery, but also in *choleriform diarrhœas*. The drug appears to exert a direct influence upon the hepatic and intestinal glands, and may be tried with great hope of success wherever there is decided glandular derangement. In 1890 (*London Lancet*, ii.), Surgeon-Major Harris used in dysentery the ipecacuanha root, deprived of its emetine, with alleged excellent results. His paper has given rise to considerable discussion, and Surgeon-Captain Walsh, as the result of his experiments (*Indian Med. Gaz.*, 1891), came to the conclusion that the value of ipecacuanha in dysentery depends upon its emetine, and devised a method of giving emetine in combination with biniodide of mercury, affirming that in this combination the drug does not produce vomiting. Other clinicians, however, have confirmed the statements of Surgeon-Major Harris. When the ipecacuanha root has been de-emetinized it fails to produce vomiting, or causes only very slight vomiting; and according to the latest clinical studies of Kanthack and Caddy (*London Practitioner*, 1893), it has all the curative effects of ipecacuanha in *dysentery*, and does not cause depression.

In *catarrhal jaundice*, and in *intermittents* or *remittents* accompanied by congestion of the portal circulation, ipecacuanha is often very serviceable.

As a *hæmostatic*, ipecacuanha has been recommended by Trousseau, and Pecholier asserts that in *hæmoptysis* it is a specific (*Bull. Thérap.*, xvii. 49).^{*} It has been given with asserted advantage in *flooding* after child-birth, and Dr. Carrigen claims for it *oxytocic* powers (*N. Y. Med. Journ.*, 491, 1878).

ADMINISTRATION.—As an emetic, ipecacuanha is generally administered in powder, thirty grains being given every fifteen or twenty minutes until the desired effect is produced. For a child a year old the emetic dose is five grains. Its action should be aided and hastened by large draughts of lukewarm water. As a nauseant the dose is from two to five grains. In dysentery it is generally best to begin with a full emetic dose, or with ten grains repeated every half-hour until emesis is produced. Two or three hours after vomiting, fifteen drops of laudanum should be exhibited, followed in twenty minutes by five to ten grains of ipecacuanha in *pill-form*; this should be repeated every two or three hours, the amount of the opium being lessened, and that of the ipecacuanha increased, according to circumstances. The object is to have as much of the ipecacuanha retained as possible.

^{*} Consult *Pacific Med. and Surg. Journ.*, 1876.

Another plan is to give larger doses (twenty grains), repeated every two, four, or six hours, mustard being applied to the epigastrium and opium exhibited as before; and it is said that after two or three doses tolerance is established and the drug retained. In India, enemata of ipecacuanha are often employed, either as a substitute for or an adjuvant to its use by the mouth. This treatment has recently been imitated by Chouppe and others, and has been practised quite extensively in my ward in the Philadelphia Hospital. It is undoubtedly frequently efficient in abdominal complaints, and the gastric symptoms are almost always avoided. In chronic cases the repetition of the enemata sometimes produces so much local irritation as to forbid their continuance. I have been accustomed to give a scruple of the powder with starch and laudanum, repeated every four hours. A decoction of the drug is to be preferred, as probably causing less local irritation and being more thoroughly absorbed. To an adult, Chouppe gives two injections of a decoction daily, each lavement representing two and a half drachms of the drug.

As a counter-irritant, ipecacuanha is rarely used in this country; but in England a liniment is employed composed of four parts of the powder to fourteen parts of olive oil.

The preparations for internal use are: a *syrup* (*Syrupus Ipecacuanhæ*—7 per cent., U.S.),—dose, as an emetic for an infant, thirty minims to a fluidrachm; a *wine* (*Vinum Ipecacuanhæ*—10 per cent., U.S.),—dose, the same as the syrup; and a *fluid extract* (*Extractum Ipecacuanhæ Fluidum*, U.S.),—dose, as an emetic for an adult, thirty drops. *Trochisci Ipecacuanhæ*, U.S., *Trochisci Morphine et Ipecacuanhæ*, U.S., are used in catarrh of the throat as a local application.

Emetine is not official, but has been used by Dr. Dyce Duckworth (*London Pharmaceutical Journal*, March, 1872) and his colleagues in doses of from one-twelfth to one-sixth of a grain.

SANGUINARIA—BLOODROOT. U.S.

This is the rhizome of an indigenous perennial herb, *Sanguinaria canadensis*. It occurs in pieces two or three inches long, reddish brown externally, a bright somewhat orange red internally, and, when fresh, full of a similarly-colored juice. According to the latest researches (G. König, 1891), there are four alkaloids in *Sanguinaria*: *Chelerythrine* (the most abundant alkaloid), *Homochelidonine*, *Sanguinarine*, and *Protopine*. Each of these alkaloids, except *sanguinarine*, exists in the *Chelidonium majus*. *Sanguinarine* very closely resembles, chemically, *chelerythrine*; but whilst the salts of *chelerythrine* are lemon yellow, those of *sanguinarine* are red.

PHYSIOLOGICAL ACTION.—In full doses *sanguinaria* acts upon man as a harsh emetic, and in overdoses, according to Dr. Tully, it produces, with the vomiting, burning at the stomach, faintness, vertigo, diminished vision, general insensibility, coldness, extreme reduction of the

force and frequency of the pulse, together with great irregularity of action and often palpitation of the heart, great prostration of muscular strength, and sometimes a convulsive rigidity of the limbs. Fatal poisoning of several persons occurred by it at Bellevue Hospital; but the only symptoms recorded are "racking, burning pains, and tormenting thirst."

According to Dr. Robert Meade Smith (*Amer. Journ. Med. Sci.*, Oct. 1876), *sanguinarine* causes in mammals vomiting, purging, profuse salivation, followed by collapse, dilated pupils, with sometimes clonic convulsions, and death from asphyxia. As the result of numerous experiments, he concludes that the convulsions are spinal, but associated with decreased reflex excitability, which is at first due to an excitation of Settschenow's centre, but afterwards to a depression of the spinal centres; and that there is a progressive lowering of the pulse and arterial pressure after large doses, caused partly by a direct action upon the heart, partly by paresis of the vaso-motor centres. Moderate doses of *sanguinarine* Dr. Smith finds to irritate at first the vaso-motor centres, and so produce a primary rise of the arterial centre. Muscular contractility is reduced by it, salivation greatly increased, and the respiration progressively rendered slower and shallower by a direct action upon the centre. It is probable that the principle used by Dr. Smith under the name of *sanguinarine* was really a mixture of alkaloids. According to the researches of Dr. Hans Meyer (*Arch. f. Exper. Path. u. Pharm.*, xxix., 1892), pure *chelidonine* produces a deep narcosis, with slight increase of motor and reflex activity, followed by paralysis of the spinal cord. There is during the narcosis slowing of the pulse by an action upon the heart itself and by stimulation of the peripheral *vagus*; at first there is no distinct alteration of blood-pressure, but finally paralysis of the vaso-motor centres and fall of pressure. The effect of *sanguinarine* was similar to that of *chelidonine*, differing chiefly in there being an early excitement of the motor-spinal cord and of the respiratory and vaso-motor centres, similar to those of *strychnine*; there was also increased intestinal peristalsis and secretion and increased salivation. Both alkaloids paralyzed the sensory nerves.

THERAPEUTICS.—As an emetic, *sanguinaria* has fallen into well-deserved disuse. Indeed, I have never known of its employment except as a stimulant expectorant in obstinate *bronchitis*, and even then with doubtful advantage.

ADMINISTRATION.—The crude drug is very rarely used; the emetic dose of the powder is from ten to sixty grains. Professor R. P. Thomas, in experiments upon himself and others with the alkaloid, found that in a dose of from one-eighth to one-twelfth of a grain it acted as an expectorant, without disturbing the stomach; one-sixth or one-fourth of a grain given every two or three hours generally nauseated, the emetic dose being half a grain repeated every ten minutes. One-sixth of a grain every three hours, in the course of two or three days, re-

duced the pulse from five to twenty-five beats per minute. The expectorant dose of the tincture (*Tinctura Sanguinariae*—15 per cent., U.S.) is gtt. xx to xl; of the fluid extract (*Extractum Sanguinariae Fluidum*, U.S.), three to five minims.

APOMORPHINÆ HYDROCHLORAS—APOMORPHINE HYDROCHLORATE. U.S.

Apomorphine was discovered by Dr. Matthieson and C. R. A. Wright (*Proceed. Roy. Soc.*, xvii. 455), who made it by the action of a strong solution of hydrochloric acid upon morphine. A probably better method of preparation is that of E. L. Mayer (*Berichte Deutsch. Chem. Gesell.*, Berlin, 1871, iv. 121), in which the morphine is treated with a solution of chloride of zinc at 120° C. Apomorphine occurs as a snow-white powder, which is permanent when dry, but when moist soon becomes green. Its solution suffers this change, which is probably an oxidation, in a few minutes by heat (Matthieson and Wright), and in a few hours at ordinary temperature; and in the course of some weeks the green tint deepens into a black. Potassium bichromate turns it a dense orange yellow; potassium bichromate and concentrated sulphuric acid make a dark red with it; and with neutral chloride of iron it strikes an amethyst color. It differs from morphine in being soluble in cold water. The officinal salt is soluble in six parts of water.

PHYSIOLOGICAL ACTION.—In doses of from one to five milligrammes in frogs apomorphine causes at first a stage of restlessness, which, after a time, yields to an increasing sluggishness and muscular weakness that may end in real or apparent death. In some instances there are violent convulsions, both clonic and tonic in character.* Sometimes recovery occurs after both respiration and cardiac action have apparently ceased.

When small doses (1 to 2 milligrammes) of the alkaloid are given to dogs, vomiting, without any other decided symptoms, is induced; after slightly larger amounts, the vomiting is severe, and accompanied by free salivation and muscular tremblings. After very large doses, vomiting does not occur, but a condition of intense restlessness is soon developed, the animal often jumping in the air, running about the room, howling and champing constantly. The slightest noise or alarm throws him into violent excitement and terror; with pupils dilated, ears drawn stiffly back, he endeavors to get out of the apartment, and even to climb the wall. After still larger amounts (4 or 5 gr.), to this excitement is soon added failing muscular strength, and the hind legs are dragged behind the animal in his movements. The respiration is exceedingly

* Consult E. Harnack, *Arch. f. Exper. Path. u. Pharm.*, ii. 291; Max Quehl, *Ueber der Physiol. Wirk. des Apomorphins*, Inaug. Diss., Halle, 1872; I. B. V. Bourgeois, *De l'Apomorphine*, Paris, 1872; E. Reichert, *Philos. Med. Times*, x. 110; G. Valentini, *Arch. f. Exper. Path. u. Pharm.*, xi. 399.

hurried, and convulsions are suddenly developed. The paresis and convulsions increase, so that the animal lies upon his back, kicking wildly into the air, and finally he dies asphyxiated. Rabbits cannot vomit, but the general symptoms produced by the alkaloid in them and in cats are exactly parallel with those just described as occurring in the dog. Very small doses (10 milligrammes, Harnack) suffice to kill the rabbit. On chickens and pigeons, according to C. David (*Gaz. Méd.*, 1874, p. 465), it acts very much as it does upon dogs; the stage of excitement is very marked. After death no distinctive lesions are to be found, unless, as Quehl (*loc. cit.*, p. 19) believes, there is habitually an excessive hyperæmia of the pons Varolii.

To the therapeutist the chief interest in apomorphine is in connection with its power of producing vomiting; but before taking this up I shall endeavor to portray what is known in regard to the physiological actions of the drug.

Nervous System.—The action of apomorphine upon the cerebrum seems to be that of a primary stimulant delirifacient and final paralyzant. The cause of the convulsions at present cannot be considered as made out.* According to Reichert's experiments, both the sensory and motor nerves are first stimulated and afterwards paralyzed. In opposition to the experiments of Quehl, Harnack found that the muscles in the frog around the place of injection soon lost their irritability, evidently from the poison reaching them in a concentrated form by imbibition. He also separated one hind leg of a frog from the rest of the body, leaving only the nerve intact, and then poisoned with apomorphine. After voluntary motion had ceased, the muscles of the intact leg were far less excitable than were those of the leg to which access of the poison had been prevented. These experiments have been confirmed by Reichert, and there can be no doubt that apomorphine is a muscle-poison.

Circulation.—The reports upon the action of this drug upon the circulation are somewhat discordant. Seibert (*London Med. Record*, i. 44), Max Quehl, and Bourgeois affirm that the blood-pressure is not affected even by toxic doses. Harnack, however, found after large doses in dogs a distinct fall of arterial pressure, and also that apomorphine is a direct paralyzant of the cut-out frog's heart. The latter fact has been confirmed by Reichert, who has also shown that the mammalian heart is similarly affected by the drug, and that finally this cardiac action causes a fall of the arterial pressure. Preceding the fall there was in Dr. Reichert's experiments a distinct rise of arterial pressure, which was prevented by previous section of the cord, and was there-

* The only one who has carefully studied them is Reichert, and his published account is self-contradictory. He reasons that the convulsions are chiefly spinal, and yet says that in mammals, after section of the spinal cord, except "in very exceptional cases," they are confined to the anterior part of the body.

fore probably due to stimulation of the vaso-motor centres. Therapeutic doses of the drug have no distinct action upon the force of the circulation. The pulse-rate is markedly increased by small and large doses of apomorphine, the maximum usually being reached about the time vomiting is fairly established; subsequently, in poisoning, the pulse falls below normal. Reichert believes the rise to be due to stimulation of the accelerators, and the fall to the influence upon the heart-muscle.

Respiration.—Usually the respiration-rate is increased by decided or toxic doses; although the amount of increase varies greatly, it is often very large. Harnack says that after toxic doses the rate rises very much before the occurrence of convulsions, but Reichert has not been able to observe this. During the convulsive period the respirations become irregular and unequal, and they finally grow more and more shallow and infrequent, until death results from a paralysis of the respiratory centres. Both Harnack and Reichert have noted that in the rabbit previous section of the par vagum does not prevent, but rather increases, this acceleration, so that it would seem that apomorphine stimulates the respiratory centres; but Reichert affirms that in the cat and dog no increase of the respiration-rate occurs under the action of the drug if the pneumogastrics have been cut.

Temperature.—The action of apomorphine upon the temperature appears to be very trifling and inconstant. According to Ziolkowski (*Apomorphin*, Inaug. Diss., Greifswald, 1872), the bodily heat usually falls after large doses from 0.1° to 0.6° C. Moerz noticed in one man that the temperature rose during the vomiting two-tenths of a degree; while Bourgeois affirms that in man the drug has no influence over the temperature, and Reichert has seen in animals a rise follow the hypodermic but not the intravenous injection of the alkaloid.

Emesis.—Dr. Gee (*St. Bartholomew's Hosp. Rep.*, vol. v. p. 215) was the first to announce that apomorphine is a certain and prompt emetic, producing but little nausea, and having the great advantage of acting in very small dose, a tenth of a grain being sufficient, when injected under the skin, to cause vomiting in ten minutes. His statements have been confirmed by very many observers, excepting that the dose employed by Gee is usually considered too large. Thus, Dr. Pierce (*British Medical Journal*, 1870, p. 274) employs one-fifteenth of a grain, and M. Bertrand (*Gaz. Méd.*, 1874) has vomited with 0.06 grain. The time required for action depends largely upon the amount of the drug exhibited. After very small doses twenty minutes may elapse; and in Bourgeois's experiments 0.45 grain produced violent vomiting in less than two minutes. After these large doses the emesis usually recurs once or twice at intervals of a quarter to half an hour.* The vomiting seems to be of centric origin, as Reichert has succeeded in

* For the doses required to vomit various animals, see *Gaz. Méd.*, 1874, p. 466.

producing it when the thoracic aorta was tied so as to prevent any of the poison from reaching the stomach.

A knowledge of the effects of narcotics upon the action of apomorphine is, of course, of great practical importance. There is as yet very little clinical evidence. A case of poisoning with bitter almonds has indeed been reported (*Schmidt's Jahrbücher*, Bd. clv. p. 272), in which the injection of 0.013 grain of the alkaloid was followed by prompt emesis; but it is evident that no inference in regard to narcotic poisoning could be drawn from this. It is inconceivable that there should be any differences in the relation between apomorphine and narcotism in man and in animals, and the subject has been investigated, with mostly similar but insufficient results, upon animals by several observers.* In dogs chloral retards, or, if in sufficient dose, prevents, the emesis of apomorphine; during chloroform-sleep the alkaloid is affirmed by David and Dujardin-Beaumetz to be powerless; but MM. Coyne and Budin state that it will produce emesis even during profound anæsthesia if the dose be large enough; David found that in a dog three centigrammes of morphine prevented the occurrence of the vomiting. It is plain that these experiments prove no more than that narcotics influence the action of apomorphine as they do that of every other emetic; and the probabilities seem to be that the alkaloid produces vomiting more surely than do our ordinarily used drugs. The emesis is probably the result of a stimulant action exerted upon the nerve-centres; and the fact that after toxic doses vomiting does not occur indicates that in such amounts the drug paralyzes these centres.

Local Action.—Apomorphine is not an irritant, so that the hypodermic use of even concentrated solutions of it elicits in the lower animals no evidences of pain. In man the injections have sometimes caused intense pain, probably because they had been originally improperly prepared or had undergone chemical change.

THERAPEUTICS.—There is now sufficient evidence to show that apomorphine is a safe and reliable emetic, possessed of advantages which have already been sufficiently dwelt upon. It may be used whenever it is desired simply to empty the stomach. In narcotic poisoning there is no reason why it should not be given hypodermically while sulphate of zinc or some mechanical emetic is exhibited by the mouth. As an expectorant,† apomorphine is employed with asserted great advantage in the suffocative catarrh of infants, when an emetic is required to get rid of the bronchial exudation. Under these circumstances it is said not only to act efficiently as an emetic, but also to render the mucus more copious and fluid. My own experience confirms the claim that in

* E. Harnack (*loc. cit.*); O. C. David (*Gaz. Méd.*, 1874, p. 465); Dujardin-Beaumetz (*Bull. Thérap.*, Oct. 1874).

† Jurnaz (*Centralbl. f. d. Med. Wiss.*, 1874, 499); Wertner (*Wien. Med. Presse*, 1876, 269); Beck (*Deutsch. Med. Wochenschr.*, 1891, 156); Murrell (*Brit. Med. Journal*, i., 1891).

acute bronchitis it rapidly causes copious, loose secretion, and that in *chronic bronchitis* it is very useful when the expectoration is scanty.

ADMINISTRATION.—As an emetic, apomorphine has usually been administered hypodermically, in doses of one-tenth of a grain, repeated every ten minutes until some effect is induced; but it may be exhibited by the stomach in double the amount. In cases of severe poisoning, where time is of great moment, it may be well to give as much as one-fourth of a grain at a single injection. In feeble persons, however, caution must always be exercised in using it, as one-fifteenth of a grain has caused death in seven minutes in an adult, fifty-four years old, suffering from chronic bronchitis with marked emphysema (*Med. Rec.*, 1877, 664). Wertner gives the expectorant dose as 0.07 to 0.15 grain for children, or double the amount for the adult, repeated every two hours by the mouth. Care must be exercised in its use in children. In Vulpian's clinic the dose is from 0.07 to 0.09 grain. Dr. Loeb (*Schmidt's Jahrb.*, Bd. clv. p. 272) gave hypodermically 0.03 grain to an infant thirteen months old suffering from capillary bronchitis: the free vomiting which was induced left the infant much exhausted. In a very few cases apomorphine has failed to vomit, and even caused startling symptoms: so that care should be exercised not to push the remedy too far. M. Carville affirms that three-tenths of a grain has caused a syncopal condition in an adult, and M. Prevost details a case (*London Medical Record*, 1875, p. 183) in which syncope and threatening collapse were apparently induced by a very small dose. In children especially must care be exercised, since, according to Harnack, the drug is very liable to produce collapse. The ordinary solutions of apomorphine undergo a rapid change, becoming green; and Dr. Loeb has reported a case in which very alarming symptoms followed the use of such a solution. M. Constantine Paul states that if glycerin be used as the sole menstruum the solution will keep three or four days. M. Carville (*Gaz. Hebdom.*, 1874, p. 408) affirms that glucose acts well as a preservative, and it is also claimed that a few drops of muriatic acid will suffice.

A very useful stimulating emetic is *mustard flour*, very prompt and even violent in its action. It acts as a mechanical emetic, and is to be used when it is desired simply to evacuate the stomach rapidly, and especially when there is torpor of the viscus. As it is generally to be had at once, it is especially useful in such emergencies as *narcotic poisoning*. It has also been commended in *nervous collapse*, such as is seen in *malarial pernicious chill*. The dose is a heaped dessertspoonful in half a pint of water, repeated, if necessary, in ten minutes. As mustard is irritant to the stomach, if it fail to act it should not be repeated more than three or four times, even in narcotic poisoning.

Squill (Scilla) is sometimes used as a harsh, stimulating emetic.

MINERAL EMETICS.

Tartar emetic is the most depressing of all the substances here spoken of as emetics. It is rather slow in its action, but the vomiting which it causes is preceded and accompanied by intense nausea, and is exceedingly violent and persistent. For these reasons, tartar emetic is rarely used simply to unload the stomach, except in the absence of more eligible substances. Its use in inflammatory diseases is discussed elsewhere.

Zinc sulphate is an excellent and prompt mechanical emetic, producing little or no irritation, and is to be preferred above all others when an emetic of such nature is needed. In *narcotic poisoning* it should be given in combination with *ippecacuanha*, and perhaps be preceded by mustard while it is being obtained from the apothecary. Thirty grains of it with fifty of *ippecacuanha* may be given as the first dose, and a mixture of fifteen grains of the former to thirty grains of the latter be administered every fifteen minutes until the desired effect is produced or one hundred grains of the zinc are taken. Beyond the latter amount it would be hardly safe to go, for fear of *gastro enteritis*.

Copper sulphate resembles the corresponding zinc salt as an emetic, but is more severe and irritating, and more capable of causing *gastro-enteritis*. The full dose in *narcotic poisoning* is from five to ten grains, which should not be repeated more than once.

Powdered *alum* is a mechanical emetic which has been especially recommended in *membranous croup*, on account of its being believed to act beneficially upon diseased surfaces in its passage up and down the throat. A heaped teaspoonful of it may be given in molasses or syrup. In my experience alum has proved an unreliable emetic.

FAMILY III.—CATHARTICS.

PURGATIVES, or cathartics, are those drugs which are employed in medicine to produce purgation, or catharsis, by increasing either the intestinal secretions or the peristaltic movements.

M. Thiry (*Sitzungsb. der k. k. Acad. d. Wiss.*, Bd. 1.) experimented upon the subject of catharsis by drawing out a knuckle of intestine through a wound in the linea alba, cutting it free from the remainder of the gut without injuring its nerves or blood-vessels, sewing together the distal and proximal ends of the main portions of the intestines so as to reform a continuous tube, and then, after closing up one end of the knuckle, forcing the other into the wound so as to make an intestinal *cul-de-sac* which could be studied through a fistulous opening. In dogs which had recovered after this operation, Thiry found that large doses of sulphate of magnesium, of senna, or of croton oil failed alike to increase the secretion of the separated piece of intestine, although they induced violent purging; further, that neither concentrated solutions of Epsom salt nor infusion of senna, even though kept in the *cul-de-sac* for some time, were able to increase its secretion by exosmose. More recently, Dr. S. Radziejewski has made an elaborate investigation of the subject (*Reichert's Archiv*, 1870, p. 37). As the result of a number of very careful analyses, he asserts that there is nothing to be found in the stools produced by sulphate of magnesium, calomel, castor oil, croton oil, senna, or gamboge, to indicate that they are anything besides the ordinary contents of the upper and lower bowels. Dr. Radziejewski confirms the fact observed by C. Schmidt, that the stools of purgatives contain a great deal of soda, but denies that this proves that they are transudations, asserting that the alkaline salts are derived simply from the pancreatic fluid. Dr. Radziejewski also corroborates the confirmation by Asp (*Ludwig's Arbeiten*, 1868) of the discovery of Moreau,* that division of the intestinal nerves is followed by free serous exudation into the gut, but denies that purgatives act by paralyzing the vaso-motor nerves, because croton oil injected into a loop of intestine which had been separated by two ligatures from the remainder of the gut caused both vomiting and purging. As no emulsifying substance was contained in the intestine, he declares that no absorption could have occurred, and that consequently the general

* *Comptes-Rendus*, t. lxxv., 1868; also Asp, *Ludwig's Arbeiten*, 1868.

intestinal disturbance was simply due to increased peristaltic action, caused by the internal local irritation of the oil propagated along the intestines. The experiments of Thiry have also been repeated by Radziejewski with croton oil and with sulphate of magnesium, as well as by Schiff (*Nuove Ricerche sul Potere digerente*, H. Morgagni, 1867) with aloes, jalap, and sulphate of sodium. In all cases the results were the same as those already noted as obtained by Thiry. Carrying his investigations still further, Radziejewski, by forming intestinal fistulæ at such positions as would enable him to study the rate of passage of the intestinal contents, found that after a dog is fed upon flesh the small intestine empties the partially-digested food into the colon so rapidly and in such quantity as to constitute, so to speak, a normal diarrhoea, and that the long delay in the exit and the hardening of the feces occur in the large intestine. The liquid which passed into the ascending colon agreed in all its characteristics with the stools of purgation. Dr. Radziejewski also claims to have established by direct experimentation that the peristaltic movements of the small intestine are affected very decidedly by drastics, and to some degree by Epsom salt, and that in all cases the large intestine is still more intensely acted upon. Although these experiments are very interesting, it cannot be allowed that they prove what is claimed for them, namely, that purgatives cause no increase of intestinal secretion, but only of peristaltic action. So much violence to natural conditions is done in the experiments after the method of Thiry that they seem to have very little weight. The assumption of Radziejewski, that croton oil confined in a loop of intestine is not absorbed, is a pure assumption, and his experiment does not warrant the conclusions drawn from it.

The other facts brought forward seem to prove only that increased peristalsis, especially of the large bowel, plays a more important rôle in the indication of diarrhoea than has been assigned to it.

Leaving out of sight for the moment all clinical evidence, the fact that previous section of the par vagum prevents the action of purgatives* is opposed to the German theory, since it is almost certain that the division of the nerves of the neck does not arrest peristaltic movements. Further, Armand Moreau (*Archives Gén.*, 6e sér., t. xvi. p. 234) has found that a solution of Epsom salt placed in a knuckle of intestine isolated by means of two ligatures does cause a serous exudation into it, and in repeating M. Thiry's experiments (*Gaz. Méd.*, 1871) he has obtained opposite results. His experiments indicate three possible sources of fallacy in the work of the previous investigators: first, if the Epsom salt be not kept in the intestine for a sufficient length of time (some hours), no transudation occurs; second, in some cases the inner end of the isolated piece of intestine fails to adhere, so that the opening is not obliterated, and the matters injected into the arrested

* See paper by the author, *American Journal of the Medical Sciences*, vol. ix., 1870.

cul-de-sac really pass into the peritoneal cavity; third, atrophy of the mucous membrane and glandular apparatus of the *cul-de-sac* often follows almost at once upon the operation, and of course necessitates a negative result in the subsequent experiments. Dr. Lauder Brunton, in a communication to the Medical Society of London, states that he has repeated Moreau's experiments, and found that sulphate of magnesium injected into the intestine of a cat caused about two-thirds of a drachm of fluid to be secreted in four hours by each inch of the bowel operated on, although the proportion of sulphate was only one grain to an inch (*Med. Press and Circular*, Dec. 31, 1873). In further experiments by Dr. Brunton, gamboge, elaterium, and croton oil gave results similar to those of the Epsom salt (*Practitioner*, May, 1875). M. Vulpian has also repeated the experiments of Moreau, and found that both sulphate of magnesium and jalap provoke a "true intestinal catarrh," the vegetable cathartic at the same time increasing the peristaltic action, but the saline having no such effect (*Gaz. Méd.*, 1873, p. 300). M. Legros (*Ibid.*), and M. Van Braam Houckgeest (*Hüger's Archiv*, 1872, p. 266), have experimentally determined that salines do not increase the activity of the peristaltic movements.*

* Dr. Matthew Hay (*Journ. Anat. Physiol.*, xvi., xvii.) has exhaustively investigated the action of saline cathartics. Space is wanting in which to discuss his article in detail, but the following are his results as formulated by himself:

1. A saline purgative always excites more or less secretion from the alimentary canal, depending on the amount of the salt and the strength of its solution, and varying with the nature of the salt.
2. The excreto-secretory action of the salt is probably due to the bitterness as well as to the irritant and specific properties of the salt, and not to osmosis.
3. The low diffusibility of the salt impedes the absorption of the secreted fluid.
4. Between stimulated secretion on the one hand, and impeded absorption on the other, there is an accumulation of fluid in the canal.
5. The accumulated fluid, partly from ordinary dynamical laws, partly from a gentle stimulation of the peristaltic movements excited by distention, reaches the rectum and produces purgation.
6. Purgation will not ensue if water be withheld from the diet for one or two days previous to the administration of the salt in a concentrated form.
7. The absence of purgation is not due to the want of water in the alimentary canal, but to its deficiency in the blood.
8. Under ordinary conditions, with an unrestricted supply of water, the maximal amount of fluid accumulated within the canal corresponds very nearly to the quantity of water required to form a five- or six-per-cent. solution of the amount of salt administered.
9. If, therefore, a solution of this strength be given, it does not increase in bulk.
10. If a solution of greater strength be administered, it rapidly increases in volume until the maximum is attained. This it accomplishes in the case of a twenty-per-cent. solution in from one to one and a half hours.
11. After the maximum has been reached, the fluid begins gradually and slowly to diminish in quantity.
12. *Ceteris paribus*, the weaker, or, in other words, the more voluminous, the solution of the salt administered is, the more quickly is the maximum within the canal reached; and accordingly purgation follows with greater rapidity.
13. Unless the solution of the salt is more concentrated than ten per cent., it excites little or no secretion in the stomach.

The experimental evidence bearing upon the question under discussion is, so far as I know, all included in the foregoing summary: it is very far from demonstrating that increased peristalsis, and not increased secretion, is the cause of the watery stools produced by purgatives. The evidence, both experimental and clinical, is indeed overwhelmingly in favor of increased secretion. The facts proved by clinical observa-

14. The salt is absorbed with extreme slowness by the stomach of the cat.
15. The salt excites an active secretion in the intestines, and probably for the most part in the small intestine, all portions of this viscus being capable of yielding the secretion in almost equal quantities.
16. The bile and pancreatic juice participate very little in the secretion.
17. The secretion is probably a true *succus entericus*, resembling the secretion obtained by Mooren after division of the mesenteric nerves.
18. The secretion is promoted by local irritation of the intestine, as by ligatures, but only in the immediate vicinity of the irritation.
19. Absorption by the intestine generally is reflexly stimulated by such irritation (the effect of numerous ligatures applied at points remote from the seat of the injected salt being to diminish the amount of purgative fluid by accelerated absorption).
20. If the salt solution be injected directly into the small intestine, the stronger within certain limits the solution is, the greater will be the accumulation of fluid within the intestine.
21. This difference is not observed when the salt is administered *per os*, as the strong solution becomes diluted in the stomach and duodenum before passing into the intestine generally.
22. The difference is due to the local action of the salt on the mucous membrane, and probably more to an impeded absorption than to a stimulated secretion.
23. When the salt is administered in the usual manner, it appears, in the case of the sulphate of magnesium, and sulphate of sodium, to become split up in the small intestine, the acid being more rapidly absorbed than the base.
24. A portion of the absorbed acid shortly afterwards returns to the intestines.
25. After the maximum of excretion of the acid has been reached, the salt begins very slowly and gradually to disappear by absorption, which is checked only by the occurrence of purgation.
26. During the alternations of absorption and secretion of the acid, it is the salt left within the intestine which excites secretion, the absorbed and excreted acid exerting no such action while in the blood, or during the process of its excretion, as Headland believed.
27. The salt does not purge when injected into the blood, and excites no intestinal secretion.
28. Nor does it purge, when injected subcutaneously, unless in virtue of its causing local irritation of the abdominal subcutaneous tissue, which acts reflexly on the intestines, dilating their blood-vessels, and perhaps stimulating their muscular movements.
29. The sulphate of sodium exhibits no poisonous action when injected into the circulation.
30. The sulphate of magnesium is, on the other hand, powerfully toxic when so injected, paralyzing first the respiration and afterwards the heart, and abolishing sensation or paralyzing the sensory-motor reflex centres.
31. Both salts, when administered in the usual manner, produce a gradual but well-marked increase in the tension of the pulse.
32. According as the salt-solution within the intestine increases in amount, there occurs a corresponding diminution of the fluids of the blood.
33. The blood recoups itself in a short time by absorbing from the tissues a nearly equal quantity of their fluids.
34. The salt, after some hours, causes diuresis, and with it a second concentration of the blood, which continues so long as the diuresis is active.
35. As the intestinal secretion excited by the salt contains a very small proportion of organic matter as compared with the inorganic matter, the purgative removes more of the

tions and by experiment—that purgatives increase greatly the secretion in an isolated knuckle of intestine, that various purgatives act when taken into the blood, and that in these cases elimination by the bowels occurs; that at least some purgatives (Headland, *Action of Medicines*, London, 1867, p. 443), when given by the mouth, are absorbed, disappearing from the alimentary canal and reappearing when purgation occurs; that the stools induced by overdoses of various drastics, as elaterium, are so enormous as to cause the profoundest depression, and even choleraic collapse, in a very few hours; that the discharges caused by hydragogues contain a large percentage of soda, the alkali of the serum; that the relief obtained in portal congestion by the depletion of salines is very marked—are, when viewed together, to my mind, incompatible with any other belief than that purgatives cause increased secretion, as well as, in many cases, increased peristalsis, in the alimentary canal.

The question of the action of drugs upon the flow of bile is a very important one, the evidence concerning which is best considered under two headings: first, the experimental; second, the clinical.

The experiments upon this subject which have attracted most attention are those of Dr. Scott, and of the Edinburgh committee, of which Professor Bennett was chairman and Drs. Rutherford and Gamgee the workers. The method employed both by Dr. Scott and by the Edinburgh committee was to make biliary fistulæ in dogs in the usual physiological method, and, after recovery from the operation had taken place and the bile regularly escaped by the external orifice, to administer the drugs, especially calomel and podophyllin, and study the effects upon the excretion of bile. Of the accuracy of their experiments I do not think there can be any reasonable doubt. I believe they prove that in dogs with biliary fistulæ mercury has no effect upon the flow of bile unless given in such quantities as to deteriorate the general health, when it diminishes the biliary secretion. The result does not, however, warrant the further conclusion that mercury does not increase the flow of bile in healthy dogs. The animals were in such an unnatural condition that, in spite of the daily ingestion of much more than the normal amount of food, they progressively emaciated, and finally died apparently of inanition: moreover, the innervation and probably also the blood-supply of the liver was very much interfered with. Under these circumstances it is clearly conceivable that the mercurial or other purgative might in the uninjured

latter than of the former from the blood. In certain cases a large quantity of the milt of the blood is thus evacuated.

36. The amount of the normal constituents of the urine is not affected by the salt.

37. After the administration of sulphate of magnesium much more of the acid than of the base is excreted in the urine.

38. The salt has no specific action in lowering the internal temperature of the body, or has it only to a very small extent.

39. It reduces, however, the absolute amount of heat in the body.

dog affect the biliary secretion, and yet fail to do so in the experiment, hindered by some obscure yet efficient cause. Dr. A. Rohrig experimented (*Stricker's Medicin. Jahrbücher*, 1873) by a method which simulated more closely the natural conditions; although even the results which he thus obtained do not seem to me conclusive. In curarized dogs in which life was maintained by artificial respiration, he placed a glass tube in the gall-duct so that the bile could escape only through it. Under these circumstances, of course, after a time secretion ceased; and Dr. Rohrig experimented not only on the effect of remedies upon the secretion while it was naturally going on, but also on their power of re-establishing it. He found that large doses of croton oil (eighteen drops) thrown into the duodenum caused an immediate very great increase, or a re-establishment, of the secretion. After the oil, the vegetable cathartics were most active, decreasing in power in the following order: colocynth, jalap and aloes, rhubarb and senna. Castor oil had very little influence, as had also the bitter salts. Calomel, even in large doses (twenty grains), very rarely re-established the secretion, but its power of increasing and maintaining it beyond the natural time for cessation was very marked.

Professor W. Rutherford, in an extended and laborious research, used the method of Röhrig with some improvements (*Trans. Roy. Soc. Edinb.*, xxix.). The drug, mixed with bile to facilitate absorption, was injected directly into the duodenum by means of a hypodermic syringe. The results obtained may be briefly summarized as follows:

Croton Oil in enormous doses neither purged nor affected the biliary secretion.

Podophyllin very greatly increased biliary secretion, especially when in such small doses that it did not purge severely.

Aloes very greatly increased biliary secretion, the doses used not purging greatly.

Rhubarb, *Colchicum*, *Iridin*, *Colocynth*, *Jalap*, *Sodium Sulphate*, *Sodium Phosphate*, *Rochelle Salt*, very greatly increased biliary secretion, at the same time purging.

Senna, *Taraxacum*, *Scammony*, *Gamboge*, *Castor Oil*, *Magnesium Sulphate*, *Ammonium Chloride*, acted very feebly, if at all, upon the liver.

Leptandrin, *Sodium Chloride*, *Potassium Bicarbonate*, had some, but not a powerful, effect on the liver.

Euonymin, *Sanguinarine*, *Ipecacuanha*, exerted a very powerful influence on the secretion of bile, and did not purge.

Calomel had no effect on the biliary secretion, but when to it a minute proportion of corrosive sublimate was added the effect was very marked; *Corrosive Sublimate* acted as a very powerful biliary stimulant.

There is one objection to the experiments of Rutherford and Vignal, entirely independent of the method employed; i.e., there were rarely more

than two experiments with any one substance, and in several instances two experiments gave antagonistic results. It is very possible, indeed probable, that if a number of experiments had been made with each drug, the variation in results would have been much greater.

Dr. Hess (*Deutsch. Arch. für Klin. Med.*, Bd. xl.) has made a series of experiments in regard to the effects of purgatives upon peristalsis by introducing into the duodenum, through a gastric fistula, a distensible ball, which can be blown up by the long tube attached to it so as to fill the intestine, and noticing the rate at which the ball moves under the influence of a peristaltic movement. With this apparatus he studied the action of sulphate of sodium, castor oil, senna, and croton oil. The least effect upon peristalsis was produced by the senna, the most by croton oil. Dr. Hess also states that when, by the blowing up of the ball in the intestine, sulphate of sodium, castor oil, calomel, senna leaves, croton oil, and colocynth were prevented from passing into the lower intestine, they failed to purge, although when introduced below the obstructing ball by a narrow tube running through it they at once caused diarrhoea. These experiments, if confirmed, would prove that the purgatives mentioned must come in direct contact with the lower part of the small intestine to produce liquid stools.

What is to be drawn from these various facts? Evidently, I think, but one conclusion,—that the experimental evidence at present does not warrant positive deductions as to the effect of purgatives upon the biliary secretion of healthy dogs. The canine diet and digestion are so different from the human that it is to be expected that medicines acting upon the digestive apparatus will influence dogs differently from man: thus, I have given doses of elaterium that would have killed a man to some of the carnivora without causing the slightest purging. In view of these facts, the only fairly deducible conclusion in regard to the experimental evidence that has been brought forward is, that it must be received with the greatest reserve or be entirely laid aside when we desire to study the question as to the cholagogue action of remedies upon man, and that our conclusions are most safely based upon clinical evidence.*

* Confirmatory to these conclusions, which I have left as in the seventh edition, are the results obtained in an elaborate series of experiments made by Professors Prevost and Binet (*Revue Méd. d. l. Suisse Rom.*, 1888) upon dogs with permanent biliary fistulae. According to these results drugs may be arranged as follows:

GROUP I.—Substances augmenting greatly the flow of bile: Oil of turpentine and its derivatives, chloride of potassium, benzoate and salicylate of sodium, salol, eononymia, muscarine.

GROUP II.—Substances slightly and inconstantly increasing bile: Bicarbonate and sulphate of sodium, chloride of sodium, Carlsbad salts, propylamin, rhubarb, hydrastis.

GROUP III.—Substances determining diminution of bile: Iodide of potassium, calomel, strychnine.

GROUP IV.—Substances without action upon the secretion of bile: Phosphate of sodium, chloride of lithium, corrosive sublimate, arsenic, alcohol, ether, glycerin, quinine, caffeine, calumba, senna, pilocarpine, kalin.

In regard to the drastics, there can be little doubt that almost any irritant purgative will to a greater or less extent increase the escape of bile, probably both by increasing its flow into the duodenum and by sweeping it out of the small intestine before absorption can take place. There are, however, two actively purgative substances for which it is especially claimed that they are cholagogues,—namely, calomel and podophyllin. The discussion of the action of these will be found under their respective headings.*

Dr. Hugo Heinrichsen has found (*Schmidt's Jahrb.*, Bd. ccii. p. 214) that the excretion of urine is diminished by purgatives,—very much so by Glauber's and Epsom salts, slightly by castor oil and compound liquorice powder. The solids of the urine are not sensibly affected by the vegetable cathartics. Under the influence of the salines the solids of the urine are increased. Glauber's salt is said to be partially converted into an alkaline carbonate, and to give thereby an alkaline reaction to the urine.

Various divisions of purgative medicines have been proposed by different authors; but probably the most convenient arrangement is as follows:

1. *Laxatives*.—Medicines which simply unload the bowels, and are not able to cause active purgation, even when given in very large doses.

2. *Purges*.—Medicines which purge actively, but are not capable of acting as poisons, even in very large amount.

3. *Hydragogues* (including the *Salines*), which produce very large watery stools without much irritation. In overdoses, medicines of this class assume some of the characters of those of the next.

4. *Drastics*, which cause great irritation of the alimentary mucous membrane, and in overdoses are violent poisons.

It must be borne in mind that this classification is somewhat artificial; that the effects of the remedies depend much upon the doses in which they are administered, so that in sufficiently minute quantity a drastic may act as a laxative; and that the dividing-lines between the groups are not very distinct.

Enemata.—When it is desired simply to unload the lower bowels, the object can often be advantageously attained by injecting various materials into the rectum, so as by mechanical distention, or by irritating the mucous membrane, to stimulate the peristaltic action. The simplest, least irritant, and least active *enema* is one of cold water. In cases of habitual constipation, especially when complicated with piles,

* In Rosenberg's experiments upon dogs it was found that sodium salicylate increased the quantity and diminished the consistency of the bile; that turpentine had a slight stimulant power; whilst the Carlsbad salts seemed rather to increase than decrease the biliary flow. Neutral oils were found to have a much greater power of stimulating biliary secretion than any other food or drugs, with the single exception of ox-gall. This is interesting in conjunction with the excellent results which are asserted to have been obtained in gall-stone and chronic hepatic torpor by the exhibition of from three to five ounces of olive oil after meals.

the injection of a pint of cold water at a fixed hour daily often acts most kindly. The ordinary *opening injection* consists of a pint of water, and a tablespoonful, each, of salt, molasses, and soft soap; castor oil is often added to it, and, if it be desired to make it very active, a teaspoonful of oil of turpentine.

Forced enemata.—The forced injection of large quantities of water for the relief of certain diseased conditions has long been employed in an irregular way; but the practice has become more common since Gustav Simon has proved the possibility of readily filling the large and even the small intestine, by forcing water into the rectum and through two patients suffering from intestinal fistula, the opening leading in the one case into the large intestine about the junction of the cæcum and the ascending colon, in the other probably into the small intestine (*Archiv f. Klin. Chir.*, xv.). Mosler has experimented on a patient in whom a finger introduced through the fistulous opening could feel the ileo-cæcal valve. Using a method to be shortly described, he found that in two minutes from the time water first entered the rectum it commenced to stream from the orifice, having traversed the whole length of the large intestine (*Berlin. Klin. Wochenschr.*, No. 45, 1873).

Forced enemata are of especial value in *intussusception*, in which disease they have not rarely relieved the symptoms at once by mechanically distending and unfolding the invaginated gut. Dr. Mosler also commends them in *hernia*, and has employed them as *anthelmintics*. As such they are, of course, especially useful against the *oxyuris vermicularis*, which often inhabits the whole of the large intestine; but Dr. Mosler succeeded with them in removing a large *tape-worm*, probably from the colon. Especially in the case of the *seat-worm*, the vermifugal enemata should be medicated; and probably the safest and most efficient substance for this purpose is quassia. Dr. Mosler used a tablespoonful of chlorine-water to every pint and a half of injection. In various *catarrhal* and other diseases of the large intestine, Mosler commends these large enemata as a means of cleansing the gut, removing acrid secretions or foreign matters, and applying local treatment. A. Röhrig (*Experim. Untersuch. ü. d. Physiol. der Gallenabsonderung*, Vienna, 1873) having found that intestinal injections of water have a very great influence over the secretion of bile, Dr. Mosler has been led to try forced enemata in *catarrhal* and other *jaundices*, with asserted good results. I have myself used in *chronic dysentery* forced enemata of a drachm of nitrate of silver dissolved in a half-gallon of water, with excellent results; and the method is undoubtedly applicable to the treatment of *acute colitis*,—cold, chloral, sublimate of bismuth, or other agencies or remedies being used *pro re nata*.

In administering these large injections a syringe should never be used. The apparatus to be provided consists of a rectal tube of hard rubber, with a conical point, below which are several good-sized openings; an india-rubber tube, two feet and a half long, fitted to the rectal

tube; and a funnel. The patient should lie upon his back, with the hips elevated. The tube being introduced into the rectum, the free end with the funnel is raised vertically, and water poured into it. When it is desired to force fluid into the small intestine, much depends upon the introduction being performed slowly, and the patient should be placed upon his knees and shoulders, so that the pelvis may be much higher than the shoulder. It is essential that the tube be fitted with a cock, or be pinched, so as to regulate the passage of the liquid. In this way from five to nine pints are readily injected.

Hypodermic Use of Purgatives.—The question as to the possibility of producing purgation by hypodermic medication is of very great importance. In 1881 (*Zeitsch. f. Klin. Med.*, Bd. iv.), Dr. A. Hiller, as the result of an elaborate investigation, came to the conclusion that very rarely is the hypodermic injection of the purgative justifiable, it being usually much better when the drug cannot be given by the mouth to give it by the rectum. He found four substances more or less suitable for hypodermic use,—namely, aloin, cathartine acid, the pure colocynthin of Merck, and citrullin of Merck; all of these substances, however, producing much pain at the point of injection. This investigation has led to further study, especially by Dr. Kohlstock (*Charité Annalen*, xvii., 1892), who found that, notwithstanding the consentaneous use of cocaine, all the drugs commended by Hiller produce so much local irritation as practically to forbid their use, but that most excellent results may be obtained by administration through the rectum, the passages being free and unaccompanied by pain. Meyer has found that the Barbadoes aloin acts freely when given hypodermically. Unfortunately, its solution in warm water is so unstable that when it is used hypodermically the crystals are deposited in the subcutaneous tissues and act as violent irritants. The glycerin solution is more permanent, but according to Meyer, the best vehicle is formamide.*

The indications to fulfil which cathartics are used are as follows:

1. *To unload the bowels.*—It is not necessary, in a work like the present, to say anything about the evil results of retained fecal matter, but only to point out the methods of relief. Before this can be done to advantage, however, a summary of the causes of *constipation* is required. Constipation may be well divided into acute and chronic. *Acute or temporary constipation* is that which occurs under special, transient circumstances, as in convalescence from acute disease, and in pregnancy. It is to be relieved by the use of laxative articles of diet, and, this not sufficing, by laxatives or purgative medicines. It should

* The following formulæ are recommended by Kohlstock for rectal use: Acid. catharticus, \mathfrak{ss} ; senna, gr. iii; aq. dest., gr. vii; natr. bicarb. ad react. alkalin., q s.—Colocynthin, gr. i; alcohol, gr. xii; glycerin, gr. xii.—Citrullin, gr. ii; alcohol, gr. xlix; glycerin, gr. xlix.—Aloin, gr. xv; formamide, $\mathfrak{z}\text{ss}$. For rectal use a solution of aloin in glycerin may be substituted. Kohlstock gives the full purgative dose by the rectum as—aloin, 15 grains; cathartine acid, 6 grains; colocynthin, 0.04 grain; citrullin, 0.02 grain.

never be forgotten that acute constipation is sometimes due to organic affections of the alimentary canal, such as enteritis or intussusception, or is caused by mechanical obstacles, such as a hard foreign body or an enormous gall-stone. It is evident that such cases are not simple constipation,—that the treatment required is essentially different from that of the latter affection, and is various according to the lesion. For the diagnosis and treatment of these diseases the reader is referred to works on the practice of medicine. *Chronic constipation* may be due to sedentary habits of life; to habitual overwork, especially of the nervous system; to a deficiency of intestinal secretion and of peristalsis, apparently natural to the individual and without obvious cause; to long-continued voluntary habit of restraining the desire to go to stool; to lead or other forms of poisoning; and to diseases of the nervous system producing a paralytic state of the intestinal muscular fibres. It is evident that in the treatment of these various forms of constipation due regard must be paid to the cause, which should always, if possible, be removed. There are also certain cardinal principles which apply to the treatment of all forms of chronic constipation. They are as follows:

1. A voluntary effort at defecation is to be daily made at a fixed hour, whether the desire exists or not.

2. Medicines are to be avoided as far as possible, a sustained effort being made to regulate the bowels by means of diet.

3. In very many cases the daily use of enemata of cold water, with attention to diet, suffices to attain the desired result.

4. If medicines become necessary, as small an amount as will suffice, and the mildest drugs, are to be used. Purgatives or laxatives are at best merely temporary devices, and if abused in costiveness increase the trouble. So far as can be, the attempt should be to produce a permanent impression, an alteration of the intestinal glandular action or peristalsis. Thus, when atony of the muscular coat exists, strychnine, or, according to recent experiments and clinical observations, Calabar bean, may be employed; if the hepatic or other glands are habitually torpid, nitro-muriatic acid may be administered.

When constipation is attended with low spirits and a coated tongue, it is almost always due to a deficiency of secretion, and may be looked upon as a form of dyspepsia: in such cases nitro-muriatic acid is especially valuable, but sometimes a mild mercurial course seems almost imperative.

A second use of cathartics under the present indication is to remove offending materials, as indigestible or irritant food, foreign bodies, acrid discharges, etc. For these purposes a brisk, quickly-acting purgative is generally best.

2. *To deplete.*—On account of the large serous flow which they produce, the hydragogue cathartics when freely exhibited cause a very decided general depletion.

Local depletion by means of cathartics is called for in *congestion of the portal circulation*, as well as in *dysentery* and other acute intestinal inflammations. Under the first of these conditions may, we think, be included without violence cases of the so-called "*torpidity of the liver*," which will be discussed in the article upon calomel. In *acute intestinal inflammations* the salines are to be preferred when depletion is desired, as they produce very large serous discharges and are not at all irritant.

3. *To promote absorption.*—By emptying the blood-vessels the cathartics favor the absorption of the exuded fluid in general dropsy. For this purpose the hydragogues, and especially elaterium, are the best purgatives. The production of catharsis is the surest method of relief in general dropsy, also in *ascites*; in other forms of local effusion its effects are less marked. As, however, purgation is the most exhausting of all the plans employed for the cure of dropsy, due regard must always be had to the strength of the patient. It is frequently necessary actively to support or even to stimulate while it is being carried out.

4. *To revulse.*—The long tract of the alimentary canal affords a great extent of surface upon which to practise revulsion in certain brain-diseases, as in *mania* and rheumatic or gouty irritation of the *cerebrum*. In *hyperæmia* of the brain, purgatives do good by depleting as well as by acting as revulsives. The drastics should be preferred.

5. *To eliminate.*—It cannot be doubted that the use of purgatives in such diseases as fevers and cholera, with the idea of eliminating some *materies morbi*, rests simply upon a crude, unproved, and probably false pathology. In *rheumatic disease* and in *gout* it is more probable that they do good in this way, although it is by no means certain that the advantage derived from their use is not simply due to depletion. In cases of retained renal secretion, the evidence is very decided that they do aid in separating the products of retrograde metamorphosis from the blood.

6. *To influence the pelvic circulation.*—The only purgative used for this purpose is aloes, in the article upon which all that is necessary will be said upon the subject.

LAXATIVES.

As has been already stated, constipation should always, when possible, be overcome by laxative food. There are two qualities by virtue of which food is laxative. Chief of these is *bulk*. All aliment which contains a large amount of innutritious material affords a large residuum, which, by distending the intestine, stimulates peristalsis. Contrariwise, articles of diet which are highly nutritious and afford but little residuum are constipating. This holds good, more or less strictly, among the lower animals. Thus, the flesh-eating carnivora are habitu-

ally constipated, the grass-eating herbivora very generally lax. Owing to its containing so little of the innutritious portion of the grain, the finest white flour favors a costive habit, while the "cracked wheat," in which the whole grain is eaten, is laxative,—as to a still greater degree is bran, which is composed almost wholly of the husk of the wheat, the least nutritious portion of it, and therefore leaves a large residuum after digestion. *Cracked wheat* is boiled into a sort of jelly-like mass, and eaten with cream and sugar, while *bran* is taken in the form of bran bread, bran crackers, or bran mush. *Unbolted flour*, containing the whole of the grain, is about equal to cracked wheat, and is often made into bread. *Indian meal*, in the form of cakes or of mush, is highly nutritious, and somewhat laxative; *oatmeal* is decidedly laxative, scarcely so much so as bran, but much more nutritious. When it agrees with the stomach, and is easily digested, it is probably the best of all these laxative articles of food. As the oats produced in southern climates are very inferior, care should be taken to procure oatmeal manufactured from Northern grain. It should be thoroughly cooked, and is best eaten in the form of a thick porridge. In dyspepsia all of these articles sometimes disagree with the stomach and cannot be used.

Some dietary articles seemingly possess *dynamic* laxative powers,—i.e., they exert a direct action which is not mechanical, but is similar to, although far less active than, that of the true purgatives. They intensify the intestinal action. Chief among substances of this class are *molasses* (*Syrupus Fuscus*, U.S.), and its congener, *brown sugar*; *white sugar* (*Saccharum*, U.S.) probably does not share these laxative powers; *sugar of milk* (*Saccharum Lactis*, U.S.) is probably also nearly inert. Of course, great care is usually necessary in taking advantage of the laxative virtue of molasses, on account of the danger of producing fermentation and acidity in the *primæ viæ*. An obvious deduction, however, is to encourage the use of brown instead of white sugar in those of constipated habit.

There are certain foods which combine the two methods of action spoken of. Chief among these are the fresh acidulous fruits—such as apples, pears, etc.—and the dried fruits. Of the latter, the fig (*Ficus*, U.S.) is one of the most palatable, and, owing probably to the great number of small seeds which it contains, is the most efficient. Prunes are nearly as agreeable as figs. To a limited extent the finest varieties of them may be eaten raw; but they are especially to be recommended stewed. When it is necessary, a pinch of senna-leaves may be cooked with them, and, if it be not made too large, increases the activity of the dessert without affecting its flavor.

Among constipating articles of diet, it is only necessary to call attention to milk as one of the most decided of the class.

The laxative remedies of the United States Pharmacopœia are as follows:

TAMARINDUS—TAMARINDS. U.S.

The preserved pulp of the fruit of *Tamarindus Indica*, a large tree, native of the East and West India. The fruit is a broad, compressed pod, usually from four to six inches long, somewhat curved, with an exterior brown hard rind. It contains seeds enclosed in cells formed of a tough membrane, between which and the rind is an acid pulp, the medicinal part of the fruit. Tamarinds are preserved for market by stripping off the outer rind, packing the inner portion in layers, and pouring on boiling syrup. In the market they are offered as adhesive masses composed of pulp, membranes, strings, and seeds, and having a sweet acidulous taste. They contain a good deal of citric acid, much less tartaric acid, and a little malic acid. They are used chiefly in making refrigerant acidulous drinks for fever, and in convalescence as a laxative article of diet, half an ounce to an ounce or more being eaten like preserves. They enter into the official confection of senna.

MANNA—MANNA. U.S.

An exudation of the European ash, *Fraxinus Ornus*, chiefly produced in Sicily and Calabria. There are three varieties of it. The best, *flake manna*, occurs in unequal, rough, stalactite-like pieces with a crystalline or granular fracture, and is obtained in the hottest and driest weather in July and August. The next quality, *manna in sorte*, consists of pieces of flake manna, mixed with a soft brownish matter: it is obtained in September. *Fat manna*, a soft viscous mass, which exudes during the wet weather in the latter part of October and in November, is the least valuable variety. Manna has a slight odor, a sweet, mawkish taste, and should contain from forty to eighty per cent. of the saccharine, active, crystalline principle *Mannite*, which differs from ordinary sugar in not containing equal parts of hydrogen and oxygen, and is therefore not readily convertible into grape sugar or its derivative, alcohol.

THERAPEUTICS.—Manna is a gentle laxative in large doses, sometimes causing flatulence and pain. It is rarely used by itself, but is added to infusions of more powerful purgatives, to cover their taste and aid in their effects. The laxative dose for an adult is half an ounce to two ounces; for a child, one to four drachms in an aromatic infusion.

CASSIA FISTULA. U.S.—*Purging Cassia* is the pulp of a hard, blackish, cylindrical pod from one to two feet in length and about an inch in diameter, having on one side a single and on the other a double dark band, running the whole length of the pod, and marking the positions where its valves are united. The pods are produced by a large tree, *Cassia Fistula*, a native of Egypt and India. The dark, sweetish, acidulous, officinal pulp may be used as a laxative in doses of half an ounce, but is apt to cause griping. It enters into the official confection of senna.

FRANGULA, U.S.—The bark of *Rhamnus frangula*, one of the buckthorns of Europe, is considerably used abroad as a laxative, and contains a crystalline principle, *Frangulin*, besides glucosides, of which *Emodin* is also found in rhubarb; a *fluid extract* (*Extractum Frangulæ Fluidum*, U.S.) is official.—dose, ten to twenty minims. In this country it is employed very rarely, but the bark of *Rhamnus purshiana*, or California buckthorn, is very largely used under the name of *Cascara Sagrada*. It probably contains principles either identical with or allied to those found in the European bark. In many cases its *fluid extract* (*Extractum Rhamni Purshianæ Fluidum*, U.S.) acts most happily as a laxative in *habitual constipation*, although sometimes it causes griping pains and irritation of the mucous membrane. The best results are usually to be obtained by giving from ten to fifteen drops of the fluid extract one or two hours after meals; rarely half a fluidrachm given at bedtime seems to suit better an individual case.

EUONYMUS, U.S., or *Wahoo*, the bark of *Euonymus atropurpureus*, was found by Noel Paton (*Brit. Med. Journ.*, 1886, i.), when given to dogs in small dose, to increase greatly the elimination of urea and uric acids, and by Professor Rutherford to be in large dose an active cholagogue in dogs. In man its effects are often most happy in cases of *habitual constipation* and *hepatic torpor*. It acts very slowly and purges only moderately. The dose of the fluid extract is a dessert- to a table-spoonful; of its resinoid extract, *euonymin* (the best preparation), two to four grains: in cases of *dyspepsia* it may be repeated with good results two or three times a week.

MAGNESIA—LIGHT MAGNESIA. U.S.

MAGNESIA PONDEROSA—HEAVY MAGNESIA. U.S.

The *heavy* and the *light* magnesia differ only in their physical characters, the particles being differently aggregated. *Magnesium carbonate* (*Magnesiæ Carbonas*, U.S.) is manufactured by precipitating a solution of magnesium sulphate by one of sodium carbonate. If the two solutions be concentrated, the dense or heavy carbonate will fall; on the other hand, if the solutions be dilute, the precipitate will be a light carbonate. Heavy magnesia is obtained by calcining a heavy carbonate; light magnesia, by using a light carbonate. All of these substances are of a milk-white color, and occur in powder; the carbonates sometimes in very light cubical blocks. They are all practically insoluble in water, freely soluble in dilute acid, and in the presence of acids they all act as alkalis.

THERAPEUTICS.—Magnesia and its carbonate act in the same manner upon the human economy, being both antacid and laxative. For their purgative powers they are probably dependent upon the presence of acids in the primæ viæ, and hence their effects vary. They are sometimes taken as habitual laxatives by persons suffering from *acid dys-*

pepsia; but, as they are said at times to accumulate in the intestines and to do harm mechanically, this use of them should be discountenanced. They are very frequently employed in conjunction with Epsom salt, senna, or other of the more powerful purgatives, on account of their antacid properties. Their chief use is in acute acid dyspepsia, in sick headache, in some forms of diarrhoea with excessive acidity in children, in gout, rheumatism, and in various cutaneous affections,—wherever, in a word, a laxative antacid is indicated.

ADMINISTRATION.—The dose of the carbonate is, for a child a year old, from five to twenty-five grains, according to the effect desired; for an adult, half a drachm to half an ounce; that of the magnesia is about one-fifth less.

SULPHUR.

Sulphur is official in three forms: SULPHUR SUBLIMATUM, or *Sublimed Sulphur*; SULPHUR LOTUM, or *Washed Sulphur*; and SULPHUR PRÆCIPITATUM, or *Precipitated Sulphur*. The first of these is made by subliming sulphur into cool chambers, and always contains some sulphuric acid, generated during the process. When freed from the acid by washing with warm water and ammonia, it constitutes the washed sulphur. The U.S. Pharmacopœia directs the precipitated sulphur to be prepared by boiling lime and sulphur together, so as to form calcium sulphide, and precipitating this with hydrochloric acid.

The sublimed and the washed sulphur occur as sulphur-yellow, crystalline powders; the precipitated as a whitish powder, whose particles are often coherent into friable lumps. For an account of the various allotropic forms of sulphur, and its chemical properties, the reader is referred to works on chemistry. It is insoluble in water, but soluble in alkaline solutions, in alcohol, the fixed and volatile oils, chloroform, ether, etc.

PHYSIOLOGICAL ACTION.—When applied locally, sulphur is almost without influence. Taken internally, it is dissolved to some extent in the alkaline intestinal juices and absorbed. It has been detected in the milk, sweat, urine, and even in the breath. It would appear to suffer oxidation in the system; at least its ingestion is followed by increase of the urinary sulphuric acid (Regensburger, *Centralbl. f. Med. Wissen.*, 1877, 328). When in sufficient quantity, sulphur acts as a mild laxative, producing soft, semi-liquid, feculent stools, accompanied generally with much offensive flatus of sulphuretted hydrogen. It is affirmed that in some instances the latter gas has been so freely generated and absorbed as to cause systemic poisoning. Cases have also been reported in which the fumes of sulphur acted as an irritant poison; but this, without doubt, has been owing to their containing a large quantity of sulphuric acid. Its continued use has probably some effect upon nutrition; the secretions generally are slightly increased, and some have affirmed that the temperature is somewhat elevated; but the truth of this is certainly very doubtful. The results of clinical

experience indicate that it has an especial tendency to act upon the skin and mucous membranes.

THERAPEUTICS.—As an habitual laxative, sulphur has been used with asserted advantage in cases of *hemorrhoids* and of chronic *rheumatism*. In subjects of the latter disease it is claimed that it exerts a beneficial alterative influence, especially in *sciatica* and in *lumbago* and other varieties of *muscular rheumatism*. It has also been employed as an alterative in various cutaneous affections; and in the form of natural sulphur-waters, used externally and internally, there is much testimony as to its value in both rheumatic and *skin-diseases*. It is affirmed by Dr. Doit (*Gaz. des Hôpitaux*, Oct. 24, 1885) that the natural sulphur-waters are of very great value in the treatment of chronic *syphilis*, as they undoubtedly are in chronic *gout* and *rheumatism*. They may be substituted by the artificial sulphur-water described under the heading of Expectorants. Sulphur is very largely used as a parasiticide in cases of *itch*. Dr. Tilbury Fox recommends its application in the following manner. He says, "I have applied to *all papules and vesicles* the following ointment: sulphur, half a drachm; ammonio-chloride of mercury, four grains; creasote, four drops; oil of chamomile, ten drops; and an ounce of lard. This is rubbed in night and morning for three days, especially to the interdigits and wrists; the same shirt is kept on till the third day, when it is changed and a warm bath given. The use of the parasiticide for two or three days should be followed by a good washing and the discontinuance of the remedy for a night. If the patient be not troubled with itching during the night, we may conclude that the acari are killed, and all we need to do is to guard against the hatching-out of fresh acari by the light application of our parasiticide once a day to any 'pimpley' or itchy place for a few days longer, taking care that the foul clothes are well heated or scalded. 'Not too strong and not too long,' is my rule in the use of remedies for scabies. The occurrence of red, rough, erythematous patches is a sign that the remedy itself is creating a disease."

ADMINISTRATION.—Sulphur is generally given in powder, mixed with syrup or molasses. Dose, as an alterative, ten to twenty grains three times a day; as a laxative, one to three drachms at bedtime.

POTASSA SULPHURATA, U.S.—*Sulphurated Potassa* is prepared by heating together sulphur and potassium carbonate. It occurs in liver-brown fragments, which form an orange-yellow solution in water. Its taste is acrid, alkaline, and very disagreeable. When moistened, it feebly emits the odor of hydrogen sulphide.

Locally applied, the sulphuret of potassium is a very decided irritant. Taken in large quantities, it is a violent corrosive poison, and is said to have produced fatal gastro-intestinal inflammation. In medicine it has until within a very short time been employed only externally. It has been used as a stimulating ointment (3ss to 3j) in various skin-

affections, and is also used for the formation of sulphur-baths, the strength of which should vary, according to the requirements of special cases, from two to six ounces of the drug in thirty gallons of water. They should be taken warm, the patient remaining in from twenty minutes to two hours, and are said to cause a general excitement, amounting in some susceptible persons to high fever. When employed strong, they sometimes occasion a papular eruption. They have been used in *chronic rheumatism* and in various *scaly skin-diseases*.

CALX SULPHURATA. U.S. *Sulphurated Lime*.—In the *Lancet* for February, 1874, Dr. Sydney Ringer recommended in the most laudatory manner *calcium sulphide* in frequently-repeated doses of a tenth of a grain in *boils* when they appear in successive crops, and in various *scrofulous* and other unhealthy *sores*, such as occur especially in children, also in *scrofulous glandular enlargements*. The value of the remedy has been confirmed by Duhring and others; it is often given in half-grain doses. The *Calx Sulphurata* of the *Pharmacopœia* contains not more than thirty-six per cent. of pure calcium sulphide, but is the commercial article known by that name.

PURGES.

OLEUM RICINI—CASTOR OIL. U.S.

A fixed, nearly odorless oil, of a nauseous taste, obtained from the seeds of *Ricinus communis* by expression. The seeds are slightly warmed before being put under pressure, so as to liquefy their contained oil; and the crude oil obtained from them is boiled with a small amount of water, so as to coagulate its albuminous impurities. The oil was formerly manufactured by means of alcohol, also by heating the seeds or by boiling them in water, and several varieties of it existed; but these are no longer in the market. Castor oil is remarkable for being soluble not only in ether, but also in alcohol. The *castor-oil seeds*, or *beans*, as they are commonly called, contain an acrid fixed principle, *Ricin*, which makes them exceedingly poisonous.*

PHYSIOLOGICAL EFFECTS.—Castor oil acts upon the human organism as a mild but decided purgative, producing copious fluid *fecal discharges*, and in overdoses sometimes vomiting, and always purging freely. There has been much doubt as to what is the purgative principle of castor oil. The castor-oil seed contains *ricin*, a *phytalbunose* which is such a violent irritant to the alimentary canal that three seeds have produced fatal gastro-enteritis. It is, however, improbable that the mild purgative properties of castor oil depend upon the presence of even a small quantity of *ricin*. The bulk of the castor oil is *ricinolein*,

* For a very elaborate memoir on this principle by Robert and Bullmark, see *Arbeiten Pharmak. Inst. zu Dorpat*, iii.

a glyceride of *ricinoleic acid*. Many years ago, Buchheim affirmed that the peculiar fat acid of the oil was its active principle, and the recent researches of H. Meyer (*Arch. f. Exper. Pathol. u. Pharm.*, xxviii., 1890) indicate that the activities of the oil really are dependent upon the presence of ricinoleic acid. That the oil or its active principle is absorbed is proved by analogy, and by the facts that in children it sometimes purges when rubbed upon the skin of the abdomen (Canvane, quoted by Stillé), and that when taken into the stomach it has been known to exude from the skin (Ward's case, *London Med. Gaz.*, vol. x. p. 377). In regard to its existence in the stools, the testimony is conflicting. Thus, Buchheim (*Virchow's Archiv.* Bd. xii.), although he submitted the passages produced by it to careful chemical manipulation, failed to detect it or any of its derivatives in them; but Bird (quoted by Stillé) and other observers affirm that it can be seen by the eye in the dejecta, either as oil or in the form of caseous flakes. According to the experiment (quoted by Stillé) of Hale upon himself, half an ounce of castor oil injected into a vein produces malaise, nausea, faintness, anxiety, and general dulness and depression, without purging.

THERAPEUTICS.—On account of the mildness of its action and the especial property which it appears to have of soothing an irritated bowel, castor oil is constantly employed whenever it is desired simply to evacuate the intestinal canal; not so much, however, in *chronic constipation* as when a temporary action is alone required. In various inflammatory or irritative affections of the alimentary canal, castor oil is of the greatest service, partly, no doubt, by removing acrid irritating secretions or foreign materials, such as undigested food, and partly by causing a depletion of the congested vessels, but also apparently by virtue of an almost specific power, which renders it the most satisfactory cathartic in these cases. This is especially seen in the acute *diarrhæas* and even in the *chronic enteritis* of children, but also holds good in the *diarrhæas* and *dysenteries* of adults.

Within the last few years a good deal has been written in regard to the use of the leaves of the castor-oil plant as a *galactagogue*, and sufficient evidence has been brought forward to render them worthy of some confidence. A poultice made of the fresh leaves should be applied to the breasts, and a teaspoonful of a fluid extract, prepared from the same, should be exhibited three or four times a day.

ADMINISTRATION.—Castor oil is very repulsive to the palate, so much so as to nauseate, or even vomit, by its taste, some susceptible individuals. It has been the habit to administer it in emulsion with a strong mint-water, or to give it in the froth of porter or in a cup of hot coffee; but by far the best plan is to mix it with an equal part of glycerin and to add two or three drops of the oil of cinnamon or of gaultheria to each dose. The substances do not stay mixed, but separate on standing; when used, they may be made temporarily to recombine by shaking the bottle. As glycerin has feeble laxative power, an ounce of this mixture

represents a little more than half an ounce of the oil. It should be taken directly out of the spoon. The full purgative dose of the oil is half an ounce to an ounce for an adult; for an infant a year old, one to two teaspoonfuls. In dysentery it is sometimes advantageous to give the drug in small dose every three hours until a decided purgative operation is induced.

Toxicology.—Although castor oil is harmless, the beans contain an acrid principle which renders them exceedingly poisonous, three of them having sufficed to destroy the life of a man (*Med. Times and Gaz.*, May, 1861). The symptoms do not usually come on until from two to five hours after the ingestion of the poison, when severe abdominal pain is felt, accompanied by violent vomiting and by purging, which after a time may become bloody, and soon ushers in a stage of collapse, with or without severe muscular cramps, with cold sweating skin, contracted features, thirst, restlessness, small rapid pulse, and sometimes the general appearance of Asiatic cholera. After death, intense redness and even abrasion of the stomach and of the small intestine are found. The treatment should consist in the evacuation of the stomach and bowels by mild emetics, such as ipecacuanha and warm water, and by mild cathartics, such as castor oil, provided nature has not already sufficiently fulfilled the indications, and in the free use of opium and demulcent drinks, the early external application of leeches and of emollient poultices, and the swallowing of small pieces of ice: in other words, the treatment, after evacuation, should be that of acute gastro-enteritis.

HYDRARGYRUM. U.S.

The only preparations of mercury which are used as purgatives are *calomel* and *blue mass*. Of these the first is by far the more active, and indeed is the only one which can be relied upon to purge, since the *pilulæ hydrargyri* very frequently will, if given by themselves, fail to induce liquid stools.

The chief interest in the purgative action of mercurials centres in the question as to their influence upon the liver. The evidence at present derivable from experiments upon the lower animals has already been discussed, and the decision arrived at that it must be rejected.*

When calomel is given to a healthy man in moderate purgative doses, green liquid stools are produced, which, after larger doses, are replaced by brown passages. The color of these passages has always been supposed by clinicians to be due to the presence of bile; but recently it has been affirmed that the green tint is owing to a compound of the mercury itself. Although no chemical proof of the presence of the metal or its salt has, that I am aware of, been furnished, yet it can scarcely be doubted that mercury is present in the first passages pro-

* For a very elaborate review of the clinical evidence, see Dr. Thomas R. Fraser's paper in the *Edinb. Med. Journ.*, April, 1871.

duced by calomel. The question, evidently, is not, Is mercury ever present in the green stools? but, Is it always present? or, in other words, Is it an integrant portion of them? The evidence is not so abundant upon this point as is desirable, yet seems sufficient to furnish a negative answer to the last question. Simon (*Animal Chemistry*, Sydenham Soc. Transl., vol. ii. p. 386) and Golding Bird (*London Med. Gaz.*, 1845, p. 801), in careful analyses, both failed to detect the metal; and, as the recognition of mercury is an exceedingly simple chemical problem, it seems impossible that these chemists could have overlooked the metal if it had been present. Simon's analysis was performed upon the fifth stool after the administration of a large dose of calomel. The passage was fluid, perfectly green, had no fecal odor, exhibited a mild acid reaction, and showed under the microscope a great number of mucus-corpuscles and epithelium-cells. Ether extracted from the solid residue (obtained by evaporation) a considerable amount of fat, which had an acid reaction, contained cholesterin, and was colored by biliverdin. All the other substances which were separated from the stool by water and alcohol were more or less colored by bile-pigment. Bile, bilifellinic acid, and biliverdin were found in large quantity.

The most satisfactory evidence is, however, that furnished by Michea (*Lancet*, 1849, vol. i. p. 15), who examined chemically the feces under four different conditions. First, the spontaneous dejections of six healthy individuals: no bile was detected. Secondly, green stools of three persons suffering from gastro-intestinal derangement: bile-pigment was found in one case only, and in that could not be detected after persistent vomiting had ceased. Thirdly, calomel having been given to eight healthy persons, five men and three women, bile was readily demonstrated in the green passages produced in all of the subjects. Fourthly, saline and resinous purgatives were given to five persons, but no bile could be detected in the liquid stools.

To the evidence brought forward in favor of the proposition that calomel given to healthy men causes an increased escape of bile from the alimentary canal, may be added the conclusive fact that in some persons, whose idiosyncrasies render them very susceptible to the action of calomel, it produces not merely purging, but also vomiting of bile, which is scarcely at all altered.

From the facts which have just been passed in review, the conclusion seems inevitable that mercurial purgatives given to healthy persons cause the escape of large quantities of bile from the alimentary canal.*

As is well known, when from any cause bile does not pass into the duodenum, the stools become very pale, of a peculiar potter's-clay, or even white, color. Very frequently under these circumstances, which

* Dr. J. Zawadzky (*Veatch*, 1887, abstracted, *Bull. Therap.*, 1887), as the result of his own researches, comes to the improbable conclusion that the presence of bile in the stools as the result of the use of calomel is due to the antiseptic property of the mercurial, the bilirubin being converted into biliverdin, which is prevented from undergoing decomposition.

may coexist either with diarrhoea or with constipation, mercurials will modify the color of the passages and alleviate or cure any symptoms present. In many cases the mercurials are, of course, powerless to effect the desired result; but this depends upon the cause being organic, or of some other nature not to be overcome by a mere stimulant to secretion.

As mercurials in health increase the flow of bile from the intestine, and as they will sometimes re-establish it in disease when the secretion has altogether ceased or has been very materially diminished, the conclusion seems to me inevitable that mercurials have the power of directly or indirectly increasing the secretion of bile. The only objection of any force to be urged against this deduction is founded upon the idea that the drug simply increases peristalsis in such a way as to cause the bile naturally in the duodenum to be swept out instead of being absorbed. The answer to this is embraced in the following facts: mercurials restore the color of the passages when pale from arrested secretion, often without producing diarrhoea; other even more active purgatives fail to induce the same bilious passages; when diarrhoea exists with clayey stools, the change in the color of the passages caused by a mercurial may coincide with a not increased, or even a lessened, amount of liquidity; diarrhoea ordinarily does not cause bile to appear in the passages.

THERAPEUTICS.—A mercurial purge is especially indicated by the congeries of symptoms known as "*biliousness*:" a heavily-coated tongue, bitter, disagreeable taste, heavy headache, depression of spirits, loss of appetite, slight nausea, and light-colored passages. It should be borne in mind that one or several of these symptoms may be absent in any individual case. Of all single indications for the use of calomel, the occurrence of *potter's-clay-colored* passages is the most important; and if such stools exist, and do not depend upon an organic cause, repeated small doses of mercurial should be given, whether there be constipation or diarrhoea.

In *bilious fever*,—i.e., *malarial fever with congestion of the liver*,—a mercurial purge, or several mild mercurial purges, will often, by exciting the action of the hepatic gland, be of great service in preparing the way for or aiding in the action of quinine. In *catarrhal jaundice*, mercurials, on the whole, offer, I think, the most frequently successful mode of treatment. It is evident that in such cases calomel does good not merely by its cholagogue influence, but even to a greater extent by its antiphlogistic power, no doubt lessening the viscosity of the secretions and abating the inflammatory action in the hepatic ducts. In many instances it is well to exhibit a mercurial purge to start with; but the main reliance is to be placed in the continuous exhibition of small doses of the drug until the gums are rendered slightly sore. Anything like profuse salivation is, of course, to be avoided. In *dysentery* of an acute athenic type, calomel has yielded, in my hands, better results than

any other remedy. It probably acts as an antiphlogistic and as an alterative, not only to the liver, but to all the intestinal glands. It is possible that its influence for good in some cases is connected with its bactericidal powers, since Dr. N. P. Wassilieff (*Zeitschr. f. Physiol. Chem.*, 1882) has found that it has no effect in checking the action of the digestive fermenta, but has a very pronounced influence in stopping putrefactive changes in food by killing the organisms which produce such changes. In one or two cases of *obstructive enteritis*, with severe constipation, which I have seen treated with this drug after the failure of other remedies, improvement in the local and constitutional symptoms commenced simultaneously with slight pyalism, and continued on to recovery.

RHEUM—RHUBARB. U.S.

The root of *Rheum officinale*, Baillon, and other species of *Rheum* growing in China, Chinese Tartary, and Tartary.

Rhubarb occurs in hard, irregularly cylindrical or roundish pieces, of a brownish-yellow color and peculiar bitter taste, and imparting to the teeth a sense of grittiness, due to the presence of great numbers of minute crystals of oxalate of calcium. There were formerly two chief varieties in market, the *Russian* and the *Chinese*. The first of these was the best, and was distinguished by the exterior of the pieces being cut or pared with a knife, and by a conical hole, evidently made for inspection with the point of a sharp instrument, and never reaching beyond the centre of the mass. The cause of the superiority of this brand of rhubarb was the close governmental inspection which it received on the Russian frontier. Such pieces as failed to pass the officials found their way into commerce through Turkey, and constituted the so-called *Turkey Rhubarb*, which resembled the Russian in external characters, but was of somewhat inferior quality. The *Chinese Rhubarb* was distinguished by the outside of the pieces having been scraped, and by the existence of a large hole running clear through and often retaining a portion of the cord upon which the roots had been strung to dry. Owing to the expiration and non-renewal of the treaty between the governments of Russia and of Tartary, the only officinal variety of rhubarb now in the market is the *Chinese*. Besides the true varieties just named, there is a drug in commerce which from its source is known as *European Rhubarb*. It occurs in long, cylindrical pieces, or very often is cut to imitate one of the varieties of the genuine drug, from which it is to be distinguished by its more spongy texture and by the complete or almost complete absence of grittiness when chewed.*

The active principles of rhubarb have not all been made out: it certainly contains chrysophanic acid, and a peculiar tannic acid, to

* In the past, the European rhubarb has been considered of little value: but recently it has been claimed that it is as good as the Asiatic. See *U.S. Dispensatory*, 10th ed., 1885; also Professor Radius (*Apotheker Zeitung*, Bd. vi., 1871).

which it owes its astringency. *Chrysophanic Acid** crystallizes out of alcohol in orange-yellow, golden, shining needles; out of benzole in orange-yellow or pale six-sided rhombic plates; with nitric acid it produces a fine yellow color; with the alkalies, a beautiful purple-red. According to Schlossberger, Bucheim, Meykow, and Auer, it is not purgative; but Schroff has found it to be so.† It certainly is not the chief purgative principle of the drug. The substances known as *Rhein* and *Rhabarbarin* are complex bodies.

PHYSIOLOGICAL ACTION.—Rhubarb is somewhat stomachic, tonic, actively purgative, and, owing to its tannic acid, secondarily astringent, leaving a decided tendency to constipation after the primary purgation. Owing probably to its chrysophanic acid, it gives a yellowish color to the milk of nursing women and to the urine. Rhubarb urine is to be distinguished from that of jaundice by its becoming purplish-red on the addition of an alkali. Rhubarb is asserted to affect chiefly the muscular coat of the bowels, and to purge by increasing peristalsis; but I have never met with any proof of this common belief.

THERAPEUTICS.—Notwithstanding its astringent property, rhubarb is largely used as an habitual laxative, because it does not impair, but, on the contrary, seems to strengthen, the appetite and the digestion. It should not be used in a high sthenic state of the system, or when depletion is necessary, but it is, on the other hand, the best purgative when it is desired simply to unload the bowels in a debilitated subject. In *diarrhœa*, with intestinal weakness or relaxation, it is the best purgative with which to unload the bowels of acrid secretions retained in them; and in the form of the *aromatic syrup* combined with an alkali it is especially valuable in the *summer bowel-complaints* of children when the stools are greenish and mucous.

* Under the names of *Gua Powder* and of *Araroba* or *Chrysaroba* have long been used in Brazil and the East Indies certain powders, varying from fine to coarse and from a light yellow to a dark chocolate, which are now known to be identical, and the product of a Brazilian tree. They depend for their activity upon *chrysarobin*, of which, according to Squier, they often contain as much as sixty-five per cent. *Chrysarobin* was formerly supposed to be identical with *chrysophanic acid*, but is a distinct principle. When taken internally in doses of from six to eight grains, it produces in about four hours repeated vomiting, sometimes followed by purging (I. A. Thompson, *Brit. Med. Journ.*, 1887), and it has been shown by Weyl to be an active irritant poison. It must not be confounded with *anthrarobin*, a distinct substance produced by Leibermann from alizarin (*Ber. d. Chem. Ges.*, 1888), which Weyl (*Arch. f. d. Ges. Phys.*, xliii., 1888) has proved to be free from poisonous properties. The only practical application of the *Gua powder* or its active principle is in certain *skin-diseases*, especially in *psoriasis*. According to the researches of Dr. Balmanno Squier, its power in this disorder is extraordinary. He uses an ointment made by dissolving the acid in hot lard (gr. v to ʒij in ʒi), cooling, and mixing thoroughly with a pestle. The ointment sometimes produces excessive irritation: hence it is advised to commence with a strength of not more than twenty grains to the ounce, well rubbed in twice daily. The acid stains of a dark purple; this can be removed from hair, underclothes, &c., by hot benzole, if no soap or alkali has been used. The skin and nails are said to contain enough potash to set the dye.

† See *Die Pflanzenstoffe*, p. 285.

ADMINISTRATION.—Rhubarb is seldom employed in powder, but, when used, may be given in the dose of twenty grains. In chronic constipation, small pieces of the root are very often carried in the pocket and chewed by the person affected *pro re nata*. The U.S. Pharmacopœia recognizes the following preparations: *Extractum Rhei*,—dose, five to ten grains; *Pilulæ Rhei*, each containing three grains of rhubarb; *Pilulæ Rhei Compositæ* (two grains of rhubarb, one and a half grains of aloes),—dose, two to four pills; *Pulvis Rhei Compositus* (rhubarb and magnesia),—dose, half a drachm to a drachm; *Extractum Rhei Fluidum*,—dose, twenty to thirty minims; *Syrupus Rhei*, 10 per cent.,—dose, for an infant, a fluidrachm; *Syrupus Rhei Aromaticus*,—dose, for an infant, a fluidrachm; *Tinctura Rhei*, 15 per cent.,—dose, one to two fluidrachms; *Tinctura Rhei Aromatica*, 20 per cent.,—dose, one-half to one fluidrachm; *Tinctura Rhei Dulcis*, 10 per cent.,—dose, two to three fluidrachms. The aromatic preparations are of pleasant taste and efficient, and are much used for children.

JUGLANS, U.S.—The bark of the root of *Juglans cinerea*, the common butternut, or white walnut. *Juglans* is said to be a mild cathartic, resembling rhubarb in its action, as a substitute for which it was introduced during the Revolution by the famous Dr. Rush. The dose of the extract (*Extractum Juglandis*, U.S.) is twenty grains.

ALOE—ALOES. U.S.

There are three commercial varieties of aloes, which are all obtained in a similar manner,—*i.e.*, by cutting off the thick, succulent leaves of the various plants, standing them up, allowing the juice to drain into suitable vessels, and afterwards inspissating, either by exposure to the sun or by slowly evaporating. The leaves contain a very large amount of a thick, mucilaginous juice, which escapes on pressure: hence aloes prepared by expressing the leaves or by boiling them—both of which processes are sometimes practised—is very inferior. *Socotrine Aloes* is the product of *Aloe pernyi*, which grows in the island of Socotra in the Indian Ocean, and on the southern coast of Arabia. *Barbadoes Aloes* is prepared in Barbadoes and other West Indian islands, from *Aloe vera*. These two varieties are recognized by the U.S. Pharmacopœia. *Cape Aloes* is obtained in the Cape Colony, South Africa, from *Aloe spicata*.

Aloes are darkish extracts, of a bitter, nauseous taste, yielding their virtues to alcohol, imperfectly to water, and very perfectly to alkaline solutions. The Cape aloes is said to be "characterized by its dark-olive or greenish-black color, its smooth and very glossy surface when broken, its translucency at the edges, and the fine bright-yellow color of its powder, which is slightly tinged with green." The Socotrine aloes is distinguished by its yellowish-brown or reddish-brown color, its translucent edges, agreeable aromatic odor, and beautiful golden-yellow

powder. The Barbadoes aloes is characterized by its dark-brown or reddish-brown color, its dull fracture, opaque edges, disagreeable nauseous odor, and dull olive-yellow powder. Of these varieties the Socotrine is most esteemed in human medicine. The Barbadoes is said to be the strongest, but is employed almost exclusively in veterinary surgery.

Messrs. T. and H. Smith (*Chem. Gaz.*, 1851) in 1850 discovered in Barbadoes aloes a crystalline principle,—aloin,—which was shortly afterwards found by Pereira to exist already crystallized in the sap of various species of aloes-plants, and was subsequently obtained by Groves (*Pharm. Journ.*, xvi.) from Socotrine aloes. Aloin crystallizes from its watery solution in sulphur-yellow granules, from a hot alcoholic solution in star-like groups of needles. It is neutral, odorless, of a taste at first sweetish, afterwards intensely bitter; is soluble with difficulty in cold water, freely in boiling water and in alcohol. There are three varieties of aloin,—*barbaloin*, *socaloin*, and *nataloin*, obtained respectively from the Barbadoes, the Socotrine, and the Cape aloes. The aloin of the markets is usually an amorphous bright powder, and probably of various constitution. The statements regarding the purgative properties of aloin are exceedingly contradictory, some physicians finding it a drastic purge in doses of one or two grains, others declaring that fifteen grains of it have no effect, while others affirm that it is a mild purge. The research of Dr. H. Meyer (*Arch. f. Exper. Path. u. Pharm.*, xxviii., 1890) shows the reason of some of these discrepancies. This investigator found that the Barbadoes and Curaçoa aloes yield an identical aloin, occurring in yellowish-white acicular crystals, soluble in hot water, whilst Natal aloes yields an aloin scarcely at all soluble in hot water. The Barbadoes and Curaçoa aloin act both on man and on many lower animals as a purgative, whilst the Natal aloin fails ordinarily to affect man, although it is a certain cathartic in dogs and cats. The time required for the Barbadoes aloin to produce purgation was from eight to thirty hours, which Professor Meyer believes to be due to the fact that its physiological action depends upon its undergoing chemical change in the intestines. In order to facilitate this change he exhibited with it potassium carbonate and ferrous sulphate, and found that these salts markedly hastened the effect. He also found that Natal aloin, when given to persons who had been fed for six days an exclusively animal diet, acted as a cathartic.* In my experience the commercial

* Consult *Chem. Gaz.*, 1851; *Die Pflanzenstoffe*, p. 1047; *Trans. Brit. Pharm. Soc.*, 1872; *Brit. Med. Journ.*, i., 1897, p. 747; *Bull. Thérap.*, xci. 259; *Land. Med. Record*, 1877, p. 459; *Edinb. Med. Journ.*, xx. 1002; xxii. 1087. Dr. Frommüller (*Med. Chir. Centralbl.*, 1879, xiv.) says that one to three grains of Merck's aloin dissolved in hot water administered hypodermically acts as an efficient purge; while Dr. R. Kohn affirms that he has used both aloes and aloin of three different commercial varieties hypodermically without effect, giving ten times the dose employed by Frommüller. In the lower animals Kohn found the hypodermic injections to cause gastro-enteritis with albuminous urine, and a peculiar inflammation of the kidneys: 0.1 grm. of Merck's aloin for every kilogramme of bodily weight was found to be a fatal dose for the dog. Aloin could be detected in the urine. (Method of

aloin is a moderately active cathartic in doses of one grain. An elegant laxative combination is aloin, half a grain, atropine, one-one-hundred-and-fiftieth of a grain, strychnine, one-fortieth of a grain,—dose, one to two pills.

PHYSIOLOGICAL ACTION.—Aloes is a stomachic, stimulant cathartic, remarkable for the slowness of its action. It has been supposed to influence chiefly, if not solely, the large intestine, and the clinical evidence is very strong that in overdoses it produces irritation of the rectum. The belief, formerly universal, that it is capable of producing hemorrhoids, has been very much weakened by the researches of a number of modern observers, among whom may be mentioned Troussseau and Pidoux (Stillé, *Therapeutics*, vol. ii. p. 444). Its habitual use in large doses is said to cause tonismus, a feeling of weight, heat, and uneasiness in the pelvis, and occasionally excitation of the sexual organs. Although I have used it a good deal, however, I have never seen these results. It undoubtedly has a tendency to increase the menstrual flow. Aloes is certainly absorbed, as is shown by the fact attested by Dr. Gerhard (*North American Med. and Surg. Journ.*) and other observers, that it will purge when its powder is sprinkled upon a blistered surface. Aloin has also been detected in the urine by Dr. J. Dietrich (*Inaug. Diss.*, Dorpat, 1885). Professor Stillé states that when other and quickly-operating cathartics are taken along with aloes it does not appear to modify their action, but that if it is administered seven or eight hours before a saline or other active purgative, a combined and very powerful operation is the result.

THERAPEUTICS.—Aloes in small doses is one of the best remedies for constipation of atonic subjects, especially when a stomachic stimulant is indicated. In these cases it may often with great advantage be combined with a simple bitter, one or two grains of it taken directly after meals being generally sufficient. In the constipation of plethora it should not be employed; neither should it be administered when active abdominal or rectal inflammation exists. During pregnancy it may be used as a laxative, but, unless some especial indication calls for its use, it is best avoided. Large purgative doses of it should never be given to pregnant women, as it certainly irritates the pelvic organs, and is even said to have the power of causing abortion. Formerly it was taught that aloes should not be used in hemorrhoids; but most, if not all, of the cases of this affection depend upon a condition of relaxation of the rectal veins, and Dr. Fordyce Barker (*American Practitioner*, 1872) insists upon the great value of aloes in piles, and states that Oppolzer was especially famous for his treatment of this affection, and that his prescriptions were, when piles are associated with constipation, aloes

analysis given.) *Schmidt's Jahrb.*, cxclv. 246. After subcutaneous injection, Meyer found minute quantities of aloin in the urine and large quantities in the intestinal juices. In no case in man did there seem to be any irritation of the kidneys.

and quinine; without constipation, aloes and sulphate of iron. For bleeding piles he used R.—Ferri sulphat., ʒi; Ext. aloës aq., ʒi; Ext. taraxaci, q. s. Ft. pil. no. 60. S.—One morning and evening, and increase to three a day if necessary. When costiveness accompanies atonic *amenorrhœa*, aloes alone of all the laxatives should be exhibited; and it is also of service in atonic *menorrhagia*.

ADMINISTRATION.—Aloes is very rarely or never used by itself to produce free purgation, but may be given in the dose of from ten to twenty grains; in the dose of from three to five grains it is a decided laxative. As aloes often contains sticks and other extraneous matters, the U.S. Pharmacopœia directs that an *Aloe Purificata*, or *Purified Aloes*, should be made by dissolving the crude drug in alcohol, straining, and evaporating. The preparations are: the *tincture* (*Tinctura Aloes*—10 per cent., U.S.),—dose, as a laxative, one to three teaspoonfuls; the *tincture of aloes and myrrh*, *Elixir Proprietatis* (*Tinctura Aloes et Myrrhæ*, —aloes and myrrh, $\frac{aa}{10}$ 10 per cent., U.S.),—dose, as a laxative, one to two teaspoonfuls; the *pills* (*Pilulæ Aloes*, U.S.), which contain each two grains of aloes and two grains of soap; the *Pills of Aloes and Asafetida* (*Pilulæ Aloes et Asafetidæ*, U.S.), useful in costiveness of hysterical or old subjects, each pill containing four grains of a mass composed of equal proportions of aloes, asafetida, and soap; the *Pills of Aloes and Mastich* (*Pilulæ Aloes et Mastiches*, U.S.), the famous "*Lady Webster Dinner-Pill*," each containing two grains of aloes; the *Pills of Aloes and Myrrh* (*Pilulæ Aloes et Myrrhæ*, U.S.), used in *amenorrhœa*, and containing two grains of each ingredient in every pill; the *Pills of Aloes and Iron* (*Pilulæ Aloes et Ferri*, U.S.), containing each one grain of aloes and one of dried ferrous sulphate.

SENNA—SENNA. U.S.

The leaflets of the shrubs *Cassia acutifolia*, of Nubia and Upper Egypt, and of *Cassia angustifolia*, of Southern India. The senna-leaves vary from three-fourths of an inch to an inch and a half in length, and are to be distinguished by the inequality of their bases, the two sides of the lamina or leaf-blade joining the midrib at unequal heights and angles. There are three commercial varieties of senna, which are named from the places of their export. *Alexandria Senna*, the most common variety, is distinguished by the presence of the shorter *argel-leaves*, with equal bases, by the ovate-pointed leaflets of *Cassia acutifolia*, and by the scattered mucronate-obovate leaflets of *C. obovata*. *India Senna* is characterized by the oblong leaflets, from one to two inches in length, entire and perfect. *Tripoli Senna* may be recognized by the great extent to which the leaflets are broken up. The active principles of senna have not been completely isolated, but appear to be several. *Cathartic Acid*, discovered by Dragendorff and Kubly (*Vierteljahres. f. Prakt. Pharm.*, Bd. xvi.), is undoubtedly actively cathartic, as Kubly found that fifteen grains of it dissolved in an alka-

line solution produced in six hours frequent watery discharges, with griping. R. Stockmann (*Arch. f. Exper. Path. u. Pharm.*, xix. 120) has confirmed the statements of Kubly, and devised a process for the preparing of cathartic acid in considerable quantity. He has also found that the neutral solution of cathartic acid in alkalies given to rabbits by the mouth produced after some hours violent diarrhoea, which, if the dose had been sufficient, continued until death. Post-mortem examinations revealed hyperæmia of the intestine. When injected into the blood or given subcutaneously, the salt of cathartic acid failed to affect the rabbit. It is probable, however, that cathartic acid, although the chief, is not the sole purgative principle in senna-leaves, since Bourgeois and Bouchut (*L'Union Pharm.*, Nov. 1871) found besides cathartic acid a chrysophanic acid, and a purgative principle which has not as yet been isolated, and may be an educt from the cathartic acid. The *cathartine* of the older writers is undoubtedly a complex body.

PHYSIOLOGICAL ACTION.—Senna is a very powerful cathartic, producing watery fecal discharges, and acting, it is said, as readily upon swine, dogs, cats, and horses as upon man. According to Professor Stillé, both Courten and Regnaudot found that its infusion injected into the veins caused vomiting and purging. It is undoubtedly absorbed; and Bergius affirms that it will impart its purgative property to the milk of nursing women.

THERAPEUTICS.—Whenever a brisk, somewhat irritating cathartic is desired, senna may be selected. When given alone, it is very apt to gripe severely, and is consequently more often used in combination,—especially its infusion with Epsom salt (*Black Draught*). In obstinate fecal accumulation the Black Draught constitutes a most efficient and safe remedy. It is claimed that senna does not leave a tendency to constipation after its action; and hence, in small doses, it is preferred by some as an habitual laxative.

ADMINISTRATION.—Whenever senna is exhibited, an aromatic should be united with it, to lessen its tendency to gripe. The leaves are not given in substance. The dose of the *fluid extract* (*Extractum Sennæ Fluidum*, U.S.) is two fluidrachms to half a fluidounce; the *confection* (*Confectio Sennæ*, U.S.) is a very complex but elegant preparation, used only as a laxative, in doses of one to two drachms, especially in pregnancy, and not suited to dyspeptic cases, on account of its tendency to derange the digestion. *Infusum Sennæ Compositum*, 6 per cent., U.S. (*Black Draught*), contains manna and magnesium sulphate,—a very active hydragogue purge,—dose, four fluidounces; the dose of the *syrup* (*Syrupus Sennæ*—25 per cent., U.S.) is one to four fluidrachms; the *Pulvis Glycyrrhizæ Compositus*, U.S., or *Compound Liquorice Powder*, is an excellent, pleasant laxative in doses of thirty to sixty grains.

MAGNESII SULPHAS, U.S.—*Magnesium Sulphate*, or *Epsom Salt*, is now manufactured on a large scale from dolomite, the double cal-

cium and magnesium carbonate, and from native siliceous magnesium hydrite. Magnesium sulphate ordinarily occurs in small, acicular, slowly-efflorescent crystals, containing about fifty-one per cent. of water of crystallization, soluble in their own weight of water at ordinary temperatures. By proper precautions, it may be obtained in large quadrangular prisms terminating in a four-sided pyramid or a dihedral summit. The taste is bitter, saline, nauseous.

PHYSIOLOGICAL ACTION.—Epsom salt is a most active hydragogue cathartic, producing very large watery discharges without causing any irritation of the intestines. In very large doses it is, however, capable of producing fatal hypercatharsis; and Christison reports the case of a boy, ten years old, said to have been killed by two ounces of the salt, without the induction of purgation. In the *London Lancet*, vol. ii., 1891, Dr. W. Sang reports a case of a woman, in which the ingestion of four ounces of Epsom salt in a very concentrated solution was followed by burning pain in the stomach and bowels, great dyspnoea, and collapse, with dilated pupil, muscular relaxation, and finally coma, ending in death, without purging or vomiting. Injected into the veins of the dog or rabbit the salt is a deadly poison, causing death by failure of respiration, and also depressing the heart (Dr. J. H. Reeke, *Inaug. Diss.*, Göttingen, 1881; also Dr. M. Hay). According to Curei (*Lond. Med. Rec.*, Oct. 1886), the soluble salts of magnesium first increase the blood-pressure and slow the pulse, and then lower the blood-pressure and quicken the pulse, with final cardiac paralysis. As the rise of the arterial pressure is prevented by previous destruction of the vaso-motor centre, it is probably the result of centric stimulation.*

THERAPEUTICS.—Whenever, in inflammation, it is desired to deplete through the bowels, the sulphate of magnesium offers the most advantageous method of doing it. Especially is this the case when the intestines are affected, as in *enteritis* or *colitis*. There is probably no other purgative in common use which produces at the same time such free serous evacuations and so little intestinal irritation. On account of the efficiency of its action and the watery character of its discharges, it is especially applicable to cases of *fecal accumulation* and of obstinate *colica pictorum*. The dose is half an ounce to an ounce, properly diluted. M. Luton affirms that ten centigrammes (1.53 gr.) administered hypodermically usually provoke several watery stools (*Gaz. Hebdom.*, 1874, p. 455); but the practice seems to me a very doubtful one.

* The action of the saline purgatives upon the tissue-changes of the body has been laboriously investigated by a large number of chemists, with results which are so discordant that it does not seem at present possible to come to any conclusion. The whole drift of the evidence, however, seems to me to show that the direct action upon tissue-change is very slight, and that it is incapable of producing a definite and fixed result amidst the varying and complicated daily causes which inevitably produce more or less disturbance and variation in the nitrogenous elimination. An elaborate research upon the subject has been published by Dr. London in the *Zeitschr. f. Klin. Med.*, Bd. xiii., Heft 1. Most of the literature of the subject will be found in this article, the original work of which seems to lead to the conclusion just stated.

LIQUOR MAGNESII CITRATIS, U.S.—*Solution of Magnesium Citrate* is prepared by putting into a strong bottle a syrupy solution of magnesium citrate containing an excess of citric acid, adding potassium bicarbonate, and corking tightly. On account of its agreeable taste and effervescence, this preparation is much used as a purgative. It is similar to Epsom salt in its action, but is less efficient, more apt to gripe, and more irritating. It ought not to be used in inflammatory affections of the bowels.

MAGNESII CITRAS EFFERVESCENS, U.S.—*Effervescent Magnesium Citrate* contains less free acid than the solution, and is therefore somewhat less pleasant to the taste. The dose is one to three teaspoonfuls taken in solution while effervescing.

SODII SULPHAS, U.S.—*Sodium Sulphate*, or *Glauber's Salt*, is at present manufactured from common salt by means of sulphuric acid. It occurs in six-sided, very efflorescent, striated prisms, which finally crumble into a white powder. Its taste resembles that of Epsom salt, but is more nauseous. On this account, and because its action upon the economy is similar to but harsher than that of the magnesium sulphate, in human medical practice it has been largely superseded by the latter salt. Dose, one-quarter to one-half ounce.

SODII PHOSPHAS, U.S.—*Sodium Phosphate* occurs in colorless, transparent crystals, which effloresce and become opaque on exposure. It is a tribasic phosphate, one part of water acting as a base. It is soluble in four parts of cold water, and has a saline taste, closely resembling that of common salt. In large doses it is a mild saline purgative, but as such is not at present very much employed. Within a few years the use of sodium phosphate in chronic *infantile diarrhœa* has attracted a good deal of notice. Originally recommended, so far as I know, by Dr. Routh, in his work on *Infant-Feeding*, as being a valuable nutrient or alterative in children, attention has been especially drawn to sodium phosphate by Dr. William Stephenson (*Edinb. Med. Journ.*, 1867, vol. xiii. p. 336). He believes that it acts upon the liver, and adduces much clinical evidence in favor of his views. The cases in which he especially recommends it are "infants who are being artificially reared, and who are liable to frequent derangement of the bowels; also when the phosphatic elements in the food seem deficient; where, from the character of the motions, there is a deficient or defective secretion of bile. It is thus of service in cases of chalky stools or white fluid motions, and in many cases of green stools; also in duodenal dyspepsia, and in diarrhœa and weaning." Dr. S. G. Webber (*Boston Med. and Surg. Journ.*, 1868, vol. i. p. 5) and my own experience confirm these statements. I have also obtained good results from the use of sodium phosphate in *habitual hepatic congestion*, and it seems sometimes of value in *lithæmia*. In his thesis of 1838, Dr. Haig

affirmed, as the result of his experiments, that sodium phosphate has very pronounced effect in increasing the excretions of uric acid. In a subsequent paper, however, he stated that if the phosphate contain any sulphate, or if it be in the form of the acid phosphate, or meet with an acid in the stomach which should make it an acid phosphate, it has no power in increasing uric acid excretion; so that it seems to me that at present we cannot consider sodium phosphate as having distinct relations with uric acid excretion. Dose for children, from ten grains upward; for adults, from twenty to forty grains; as a laxative, half an ounce.*

POTASSII ET SODII TARTRAS, U.S.—*Potassium and Sodium Tartrate*, or *Rochelle Salt*, is made by the addition of sodium carbonate to a solution of potassium bitartrate. It occurs in large, colorless, transparent, slightly efflorescent, prismatic or half-prismatic crystals, which are soluble in two and a half parts of cold water, and have a slightly saline taste. It is a mild saline purgative, decidedly less efficient, but much less offensive to the palate, than Epsom salt. The dose is from half an ounce to two ounces, properly diluted.

PULVIS EFFERVESCENS COMPOSITUS, U.S.—*Seidlitz Powder* is in two packets, the white paper containing thirty-five grains of tartaric acid, the blue paper forty grains of sodium bicarbonate and two drachms of Rochelle salt. When they are taken, the powders are dissolved separately, the solutions added, and the whole drunk while effervescing. They are very acceptable to the stomach, refrigerant and laxative rather than purgative. Seidlitz powders are used almost exclusively to evacuate the bowels, and exhibited after blue mass to "carry off" mercurials, etc. They should be taken on an empty stomach, as before breakfast. One powder is the usual dose; but not rarely even two powders will fail to purge.

POTASSII SULPHAS, U.S.—*Potassium Sulphate*, or *Vitriolated Tartar*, was formerly used as a purgative, but is no longer employed in medicine, except in the preparation of Dover's powder.

Sodium Sulphovinate has recently been brought forward as a substitute for Epsom salt. A very great advantage is claimed for it, in that it has a refreshing flavor with very slight bitterness, and when given in flavored syrups makes a very pleasant drink. Its action is said to be rapid and thorough. The dose is two to four drachms for children, four to six drachms for an adult.

* Hypodermic injections of sodium phosphate have been strongly recommended by M. Ed. Égasse (*Bull. Thérap.*, cxxiv., 1893) as a nerve tonic in *neurasthenia*, and even in such organic diseases as *locomotor ataxia*, *paralysis agitans*, etc. He gave from two to three cubic centimetres of the following solution: sodium phosphate, one part; glycerin, twenty parts; distilled water, twenty-five parts; alcohol, five parts. The ameliorating effects were probably of psychic origin.

DRASTICS.

As already stated, the *drastics* are those vegetable cathartics which are actively irritant. With perhaps one or two exceptions, in sufficient amount they are capable of causing fatal gastro-intestinal irritation. The line between the drastics and the stronger purgatives is, of course, placed more or less arbitrarily, since the various cathartics differ in action almost by insensible degrees. Thus, jalap, although included among the drastics in this work, might with perhaps even greater propriety be classed among the purgatives, since it is very little more active or irritant than is senna. Further, these remedies in combination seem to lose, in a measure, their power of causing irritation, and to become useful purgatives. A fact, however, which makes the classification here employed clinically useful, although it be not scientifically accurate, is that none of these remedies should be used when a purgative is desired to relieve gastro-intestinal inflammation or irritation; and, on the other hand, when a revulsive action is wished for, as in some cases of brain-disease, one of the drastics should always be selected.

JALAPA.—JALAP. U.S.

The tuber of *Ipomœa jalap*, a convolvulaceous vine growing in Mexico. Jalap comes into the market in two forms: one, that of the younger roots, which are sold undivided; the other, that of the old roots, which are brought into the market in transverse or longitudinal slices, and in pieces. The first variety consists of very hard, irregularly globular, brittle roots, about the size of a shut fist, or smaller, and often slashed with vertical incisions, made for the purpose of facilitating drying. The section of jalap is always distinctly resinous, if not to the naked eye, at least to the vision aided by a lens. The active principle is a duplex resin, one portion of which is soft, and soluble in ether, the other (*Rhodoretin*) hard, and insoluble in the latter menstruum. *Rhodoretin* is asserted by both Kayser and Mayer (*U.S. Dispensatory*) to be the purgative principle; but Mr. J. C. Long (*Amer. Journ. of Pharm.*, 1861) has shown that the soft resin is equally active. The percentage of resin varies very much in different specimens, but is much greater in those that are worm-eaten.

PHYSIOLOGICAL ACTION.—Upon dogs and horses jalap (Stillé, *Therapeutics*, vol. ii.) is said to act as a powerful hydragogue cathartic, and in overdoses as a gastro-intestinal irritant. Its active principles are absorbed, since Cadet de Gassicourt produced diarrhœa in dogs by the free application of jalap to the shaven skin, and J. Möller found the resin in the blood of dogs to which he had given it (*Inaug. Diss.*, Dorpat, 1885). Professor Stillé, however, asserts that it does not impart its purgative properties to the milk of nursing women, and that in man it is not absorbed by the skin. In man jalap produces free hydragogue catharsis, often with nausea; or, if in overdoses, violent vomiting and purging.

THERAPEUTICS.—Jalap is especially indicated when it is desirable to produce large watery stools. It is, however, very rarely used alone. A favorite combination with many practitioners is of it and calomel. In the form of the *compound powder* (*Pulvis Jalapæ Compositus*, U.S.,—jalap, thirty-five parts, cream of tartar, sixty-five parts), jalap is very frequently used with great advantage in *ascites* and also in other forms of general *dropsy*. It is believed when given in this way to exert some influence upon the renal functions: for very many cases the proportion of cream of tartar in the officinal compound powder is too small, and should be increased.

ADMINISTRATION.—The dose of powdered jalap is ten to twenty-five grains, of the *extract* (*Extractum Jalapæ*, U.S.), ten to twenty grains. The *resin* (*Resina Jalapæ*, U.S.), like the other purgative resins, is prepared by precipitating a saturated tincture with water. According to Husemann, the ordinary adulterations of jalap resin may be detected by the solubility of the substances employed in the oil of turpentine, which does not affect the genuine article. On account of its tastelessness, this preparation, as well as the similar one of scammony, is sometimes employed as a purgative for children. The dose for an adult is from two to four grains.

COLOCYNTHIS—COLOCYNTH. U.S.

The fruit, deprived of its rind, of *Citrullus Colocynthis*, or bitter cucumber, a vine growing in South Africa, Japan, Syria, Egypt, Turkey, the islands of the Grecian Archipelago, etc. The fruit is a round gourd, from two to four inches in diameter, of a whitish or pale-yellow color. It occurs in the market with or without its rind. The pulp is dry and membranous, whitish, and contains the active purgative glucoside *Colocynthin*, first discovered by Herberger.

PHYSIOLOGICAL ACTION.—The experiments of Orfila and Schroff have shown that upon dogs and rabbits colocynth acts very much as it does in man, producing copious watery evacuations, and, although not so irritant as gamboge, in overdoses causing death by gastro-intestinal irritation. If the statement of Richter that violent purgation may be induced by rubbing the abdomen with tincture of colocynth be true, the active principle is without doubt absorbed.

THERAPEUTICS.—Colocynth is rarely, if ever, used alone, but is given in combination with the other drastics, or with milder purgatives, to increase their activity. It is frequently added in small quantity, with advantage, to laxatives, especially when the constipation is somewhat obstinate. Its minute bulk is often of great advantage in these cases. Neither colocynth nor any of its combinations should be used in *dropsy*.

TOXICOLOGY.—Colocynth has not rarely produced death, preceded by hypercatharsis and the usual symptoms of gastro-intestinal irritation. The fatal dose probably varies very much. Christison records the death of a woman twenty-four hours after taking a teaspoonful and

a half of the powder. Roques chronicles a fatal result produced by less than a drachm of the powder in decoction, but, on the other hand, narrates a case in which three drachms failed to kill (Husemann, *Handbuch der Toxicologie*, p. 625), and Dr. W. A. Rolfe reports recovery after a quarter of an ounce of the powdered drug. Pregnancy existed, but abortion was not produced (*Boston Med. and Surg. Journ.*, cxavi.).

ADMINISTRATION.—Colocynth is used only in the form of the *extract* (*Extractum Colocynthidis*, U.S.),—useful as an addition to laxatives,—dose, as a purgative, three to five grains; and of the *compound extract* (*Extractum Colocynthidis Compositum*, U.S.), which contains extract of colocynth, sixteen parts, purified aloes, fifty parts, resin of scammony, fourteen parts, cardamom, six parts, soap, fourteen parts, and is a very useful purgative preparation, either as a laxative in minute dose (one to three grains), or in large dose (five to twenty grains) as an active purgative.

SCAMMONIUM—SCAMMONY. U.S.

A resinous exudation from the root of *Convolvulus Scammonia*, a vine growing in Syria. It is said to be obtained by cutting off the root obliquely about two inches from the origin of the stems, and catching in shells the few drachms of milky juice which exude from each root. From these shells it is emptied into a vessel and allowed to concreate. Before exportation it is usually adulterated with the expressed juice of the leaves and stalks, and with chalk, flour, ashes, sand, etc. This adulteration was formerly carried to a very great extent, but is at present indulged in to a much less degree. The pure or *Virgin Scammony* is in irregular, rough, fissured masses, of various sizes, commonly solid, with a dull resinous fracture, and of a dark greenish color, inclining to black. The smell is peculiar, resembling that of old cheese. The taste after a time is acrid. *Factitious* or adulterated scammony occurs in cakes of various sizes and shapes, and is sometimes spoken of as *amylaceous* or *cretaceous* scammony, according to the material used for its adulteration. The active principle of scammony is a resin, very similar to that of jalap. The proportion of this resin in the drug varies, according to the purity of the article, from eight to ninety per cent. The U.S. Pharmacopœia directs that scammony shall contain seventy-five per cent. of the resin.

THERAPEUTICS.—Scammony acts upon the system like jalap, but is somewhat more irritating, and therefore more apt to gripe severely, and is still more strongly contra-indicated in inflammatory diseases of the intestinal canal. It is decidedly less drastic than gamboge. It is never used alone, but in combination with other less active cathartics. The dose of the resin (*Resina Scammonii*, U.S.) is two to five grains.

As all the ingredients have been noticed, the present seems the proper place for the consideration of *PILULÆ CATHARTICÆ COMPOSITÆ*, U.S.—*Compound Cathartic Pills*. These popular pills contain each—

compound extract of colocynth, one and a third grains; abstract of jalap and calomel, each one grain; gamboge, one-fourth of a grain. As there is soap in the first ingredient, the calomel is sooner or later reduced to the black oxide of mercury.

The compound cathartic pills are a very efficient purgative, generally not producing much griping. They cause large watery stools, and are used when it is desired to empty the bowels and deplete from the portal circulation. On account of the mercury in them, they should not be used as an habitual laxative.

PODOPHYLLUM—PODOPHYLLUM. U.S.

The rhizome of *Podophyllum peltatum*, or May-apple, a perennial herb, growing in the Northern and Middle United States. *Podophyllum* occurs in simple or branched, cylindrical, brownish pieces, about the thickness of a goose-quill, smooth or wrinkled longitudinally, often obscurely marked with the scars of leaf-scales, and furnished with numerous rootlets or their remnants attached to the lower surface. The taste is bitterish, acrid, nauseous. The rhizome contains the alkaloid *Berberine*, but the purgative power resides in two resins, one soluble, the other insoluble, in ether.*

PHYSIOLOGICAL ACTION.—The experiments of Dr. Snow, of Dr. S. R. Percy (*American Med. Times*, vol. iv.), of Dr. F. E. Anstie (*Med. Times and Gaz.*, March, 1863), and of others, have shown that, whether administered by the mouth or hypodermically, *podophyllum* produces in the lower animals purging, with colicky pains and, sometimes vomiting. If the dose be sufficient, the stools are bloody, and after large amounts death occurs, preceded by hypercatharsis, prostration, and slight convulsions. On post-mortem examination, Dr. Anstie found intense inflammation, with ulceration of the mucous membrane of the small intestines. Upon man *podophyllum* acts as upon these animals, producing in large doses violent catharsis, accompanied by much pain, and is probably capable of acting as a fatal gastro-intestinal irritant. Ten grains produced in a strong woman violent bilious but not bloody

* Podowysotaki states (*Arch. f. Exper. Path. u. Pharm.*, xlii, 40) that he has isolated a crystalline substance (*Podophyllotoxin*) which he believes to be the active part of *podophyllum*. One-tenth of a grain of it in a cat produced fatal vomiting and purging. By the action of an alkali it is resolved into two substances, *pikropodophyllin* and *podophyllinic acid*, which also exist in the rhizoma. *Pikropodophyllin* resembles *podophyllotoxin* in its action upon the organism, but is less powerful. Dr. D. O. Braun has used *podophyllotoxin* as a purgative for children, and finds it to represent *podophyllin* completely. To a child thirteen years old he gives from six- to nine-hundredths of a grain (*Arch. f. Kinderheilk.*, li., 1880). *Podophyllotoxin* has been employed hypodermically by Drs. Dudley and Castle (*Med. News*, 1886, vol. li, p. 509). One-tenth of a grain dissolved in alcohol produced local irritation, and in only one case out of four had any decided influence upon the bowels. In experiments made upon lower animals, Dr. J. Neuberger (*Arch. f. Exper. Path. u. Pharm.*, xxviii., 1890) has found crystallized *podophyllotoxin*, when in sufficient dose, to produce violent purging, with pronounced lowering of the arterial pressure and severe nephritis; upon the central nervous system the poison appeared to have no direct influence.

vomiting and purging, with collapse, but final recovery (*Phila. Med. Times*, xii. 520). The experiments already mentioned show that it acts by being absorbed, which is confirmed by the experience of Dr. Percy, who found that its application to an ulcer was followed by its specific effects. It has been claimed that it acts especially upon the liver; and much clinical testimony has been adduced to support this view, which is also confirmed by the experiments of Rutherford (see p. 747).

Very large doses are distinctly poisonous. A child four years old was killed in this city by an unknown amount. The symptoms were repeated vomiting, slight purging, collapse, and finally coma, ending in epileptiform convulsions (Dr. T. G. Morton). An infant twenty-two months old recovered from four grains (*Australasian Med. Gaz.*, ii. 237).

THERAPEUTICS.—Podophyllum is a powerful purgative, which usually requires ten or more hours to act, and produces "bilious discharges" with griping pains. In this country it is very largely used in cases of *acute constipation*, and with very good effect; it has also been commended very highly by numerous practitioners in the so-called "*bilious attacks*." Owing to the extreme slowness of its action, it is not well adapted for combination with brisker cathartics. The same quality fits it, however, for use with calomel, it requiring nearly the same length of time as that drug to produce purgation. L. Lewis (*Brit. Med. Journ.*, 1876, ii. 546) affirms that in small repeated doses (gr. $\frac{1}{16}$ t. d.) it is a powerful stimulant of the gustatory nerves.

ADMINISTRATION.—Although an *extract* (*Extractum Podophylli*) is official,—dose, one to three grains, and a *fluid extract* (*Extractum Podophylli Fluidum*), dose, five to fifteen minims,—podophyllum is scarcely ever given in any other form than that of the resin, commonly known as *Podophyllin*. *Resina Podophylli* (U.S.) is prepared by precipitating a concentrated tincture with water: as berberine is soluble in the latter menstruum, the resin as thus obtained is free from the alkaloid. The portion of this duplex resin which is soluble in ether is certainly more actively purgative than the other part, to which, indeed, any purgative property is denied by some. Dose, as a purgative, from one-sixth to one-fourth of a grain; as a laxative, one-twelfth of a grain.

ELATERIUM.

A substance deposited by the juice of the fruit of *Ecballium elaterium*,* or squirting cucumber, a native of Greece, but cultivated in England. In the interior of the ovate fruit is an elastic sac, which contains the seeds, and at ripening becomes so distended with juice that when the fruit falls off the vine, and the support is removed from the stem end, a rupture occurs at the latter position, and the liquid with

* In Brazil the fruit of the *Momordica bucha* is used in *dropsey*, and appears to be a violent hydragogue cathartic, causing both diarrhoea and vomiting when given by the stomach, and vomiting only when given, as it usually is in Brazil, by injection. See *Lond. Med. Rec.*, 815, 1897.

the seeds is forcibly projected. The medicinal principle is said to be contained only in this inner juice. In order to avoid loss, the fruit is picked with a piece of the stalk adherent to it before ripening, and is opened by slicing. *Elaterium* occurs in light, friable, slightly incurved, greenish-gray cakes about a line thick. The taste is acrid and bitter; the fracture finely granular. Owing to the variability of commercial elaterium, the U.S. Pharmacopœia now recognizes only the active principle, *Elaterin* (*Elaterinum*, U.S.), which was first separated in a pure state by Morris (Repertor. für Pharm., xxxix. 134). It crystallizes in colorless, shining, rhombic, six-sided, odorless tables, of a very bitter sharp taste and neutral reaction. According to Dr. H. Köhler (*Virchow's Archiv*, Bd. l. p. 287), it is insoluble in water and in glycerin, readily soluble in cold alcohol, and soluble with difficulty in ether and in turpentine.*

PHYSIOLOGICAL ACTION.—Locally applied, elaterium is a very decided irritant, producing, according to Pereira, ulcerations in the fingers of those who handle the fruit and prepare the drug for market. When taken internally, it acts on man as a most powerful hydragogue cathartic, producing, when the dose and administration are properly regulated, enormous watery stools, without much irritation. On the lower animals its action is much less certain. Viborg asserts that a horse was unaffected by a pound of elaterium fruit; and I have given one and even two grains of a presumably active elaterium to a dog without producing very obvious results. If the dose be sufficiently large, all animals probably are, however, fatally affected by elaterium, perishing by progressive depression. Professor Stillé asserts (*Therapeutics*, vol. ii. p. 459) that the death is not rarely preceded by violent vomiting and purging; and even when these are absent during life, post-mortem examination reveals congestion and inflammation of the gastric and intestinal mucous membranes. In none of my own experiments, which have not been very numerous, has any purging been present; further, in Dr. Köhler's elaborate investigation (*loc. cit.*), elaterium dissolved in alcohol was injected under the skin, the powdered elaterium was put into the rectum, and was given by the mouth after the gall-duct had been tied so as to prevent the flow of bile into the intestine, and in neither case was there any purging, but prostration, apathy, disturbed respiration, salivation, and violent convulsions, ending in death. From these experiments Dr. Köhler draws the conclusion that elaterium exerts a general action upon the system, for which its introduction into the blood is all that is requisite, and also a purgative influence, for which it is necessary that there be bile in the duodenum to dissolve the elaterium and cause it to act locally on the intestine. The objection to this conclusion is that our present light seems to indicate that ela-

* For the behavior of elaterin with various reagents, and for the methods of searching for it in medico-legal investigations, the reader is referred to Dr. Köhler's memoir.

terium does not purge dogs and rabbits, even when given by the mouth. Further, elaterium applied externally will cause purging in man (see Stillé, *Therapeutics*, vol. ii. p. 459). So that the application of the conclusions arrived at by Köhler to man is incorrect. Köhler's experiments proved that in animals elaterium is absorbed, even when given by the mouth, since he found it in the urine of the poisoned dogs and rabbits.

THERAPEUTICS.—Elaterium is certainly the most efficient of all the hydragogue cathartics, producing in properly-regulated doses the freest evacuations with comparatively little pain and irritation. It is therefore indicated whenever a powerful cathartic of such nature is indicated. It is the most efficient of all the medicines of the class in general *dropsy* or in *ascites*. As, however, its action is very exhausting, great care should be exercised not to give it in too large doses, and also to support the strength of the patient during the period of purgation, and afterwards, by alcoholic stimulants, easily-digested nutritious food, and appropriate hygienic measures. In the latter stages of dropsy the injudicious use of elaterium may favor, and no doubt has accelerated, the fatal result, by intensifying the exhaustion. An idea has prevailed that elaterium is especially valuable in *uræmia*, because it produces an elimination of the urea in the stools; but I have been unable to find authority for the asserted elimination. Be this as it may, however, clinical experience has demonstrated the utility of elaterium in chronic renal disease. In order to deplete, elaterium has been employed in various diseases; but this use is not to be encouraged, and especially when there is any gastro-intestinal irritation or inflammation are the salines much preferable to elaterium. In cases of *plethora*, however, when there is a sudden *determination of blood to the head* and a very powerful impression is needed, the vegetable cathartic may be advantageously employed.

TOXICOLOGY.—Elaterium is without doubt capable of destroying life, and that, too, when not in large quantity. I know of but one recorded death,—that of a woman who took, by the advice of a quack, two and two-fifths grains of the extract of elaterium and sixteen grains of rhubarb. Violent and uncontrollable vomiting and purging came on, and proved fatal in thirty-six hours. After death, the gastro-intestinal mucous membrane showed marked evidences of inflammation. (See *Beck's Medical Jurisprudence*, 12th ed., vol. ii. p. 719.)

ADMINISTRATION.—It is not safe to commence with more than one-sixth of a grain of elaterium, to which should be united a grain of the extract of hyoscyamus and a drop of some aromatic oil. The dose of the official elaterin is one-twentieth of a grain; of the *trituration* (*Trituratio Elaterini*—10 per cent., U.S.), half a grain. Elaterium when injected hypodermically produces free purgation; but this method of administration is not justifiable, on account of the excessively severe local irritation, which has been the cause of fatal tetanus (case, *Therap. Gaz.*, vol. ii. p. 27).

CAMBOGIA—GAMBOGE. U.S.

A gum resin, obtained in Siam by breaking off the leaves and young shoots of the tree known by botanists as *Garcinia hanburii*, and catching in suitable vessels the juice as it drops. When the receptacles consist of hollow bamboos, the juice hardens into cylindrical casts, striated externally, and with a central cavity due to the loss of substance in drying. This is the so-called *pipe gamboge*. *Gamboge* in sorts occurs in irregular masses. Gamboge is a hard, resinoid substance, of a brittle, often conchoidal fracture, of a deep reddish-orange color on exposed surfaces, more yellowish when freshly broken, affording a bright-yellow powder, insoluble in water, with which it forms, however, an intensely yellow emulsion. It has little or no taste, but when chewed produces, after a time, an acrid sensation in the fauces. It contains, according to Christison, as much as seventy-two per cent. of *gambogic acid*, a resinous acid of a cherry-red color, forming red salts with alkalis. This would appear, however, to be only one of the purgative principles of the drug, since it is less drastic than an equal weight of gamboge (Christison, *Ann. Chem. Pharm.* xxiii. 185; Pabo, *Additam. quæd. ad Virtutes*, etc., Dorpat, 1831; Daraszkievicz, *Meletemata de Resinarum*, etc., Dorpat, 1858): five grains of it produced in some persons only watery evacuations, in others not even these, and as much as seventeen grains have been taken without more serious effect than severe purgation.

PHYSIOLOGICAL ACTION.—Administered by the mouth to dogs, cats, horses, and probably other of the lower animals, gamboge acts very generally as a violent drastic cathartic; but from the experiments of Schaur and of Orfila it would appear to cause sometimes simply vomiting, and, when in very large amounts, death, without any marked symptoms other than those of progressive depression. In such cases the gastro-intestinal mucous membrane was found highly inflamed, and the intensity of the irritation probably paralyzed the intestinal functions. According to Daraszkievicz and to Schaur, in order for gambogic acid to act as a purgative the presence of bile in the intestine is necessary. As it has been determined by Schaur (quoted by Husemann) that the hypodermic administration of gamboge to dogs results simply in the production of local abscesses, and as A. L. Richter asserts that when applied to raw surfaces in man it acts merely as a local irritant, it would appear that gamboge does not act by absorption, and the alkaline juices of the alimentary canal probably dissolve it so that it can readily be taken up by the villi. Nevertheless, both Gmelin and Tiedemann assert that they have found its principles in the urine. Schaur has, however, been unable to detect it in the urine of persons or of animals taking it. Even when he injected large quantities of it into the blood of dogs he failed to find it in the urine, although he did obtain a resinoid substance which he believes to be a

derivative of gambogic acid. Lewis, Abeille, and Ferriar assert that, when given in certain ways, gamboge acts as a decided diuretic. If this be true, absorption of it must occur.

THERAPEUTICS.—On account of the intense irritation which large doses of it produce, gamboge is very rarely, if ever, used alone as a purgative, but is employed to give sharpness to purgative combinations. In very obstinate *habitual constipation* it has been used in doses of one or two grains as a decided laxative. Its use as a hydragogue in *dropsy* is to be absolutely condemned, it being much less effective for this purpose, and more irritating, than various other substances. The dose of gamboge is from two to five grains, made into pill with soap, or given in alkaline solution.

OLEUM TIGLI—CROTON OIL. U.S.

The fixed oil obtained from the seeds of *Croton Tiglium*, a euphorbiaceous shrub of Hindostan and other portions of Southern Asia. This oil is quite viscid, varies in color from a pale yellow to a dark reddish brown, and has an acid reaction. Its taste is hot, acrid, and extremely persistent; its odor faint, but peculiar. Croton oil consists chiefly of the glycerites of ordinary fatty acids, but contains also a peculiar acid, *crotonoleic*.

PHYSIOLOGICAL ACTION.—Locally applied, croton oil is an intense irritant, producing upon the skin an eruption which is at first papular but in a very short time becomes pustular. This effect of the drug will be considered more in detail under the heading of Counter-Irritants. When given by the mouth, croton oil affects the horse, the dog, and probably other mammals, as it does man, producing violent purging, with severe griping, and, when in sufficient amount, fatal gastro-intestinal inflammation. The question as to whether it acts by producing a simple local impression or by absorption is unsettled. In the experiments of Hertwig (*Stillé, Therapeutics*, 2d ed., vol. ii. p. 449) and of Bucheim (*Virchow's Archiv*, xii. 1), purgation did not follow the injection of the oil into the veins of animals; but Conwell obtained a result contrary to this, and there is considerable testimony that its external use in man is sometimes followed by purging (*Stillé, Therap.*, 2d ed., vol. ii. p. 451), and even by fatal results. (*Schmidt's Jahrb.*, Bd. clxiv.; also *Kobert's Arbeiten*, 1890, iv. p. 45.)

It is probable that the oil acts on the intestine both locally and by absorption. The experiments of Kobert and of Hirschheydt (*Kobert's Arbeiten*, iv., 1890) seem to prove that crotonoleic acid is both the purgative and vesicant active principle: it exists in the oil combined with glycerin. It is believed that the glycerite is slowly decomposed in the intestines, and that the acid which is thus set free acts progressively. Certainly, Hirschheydt found that pure crotonoleic acid, which has appeared in commerce, is not a practical purgative, ten milligrammes being very uncertain in its effects; whilst large doses are prone to

produce excessive gastro-intestinal irritation. Injected into the blood, crotonoleic acid was found to be an exceedingly active depressant to the circulation. The amount of free crotonoleic acid increases in croton oil very markedly with age. On this account old croton oil, with an acid reaction, acts much more harshly than does the recent neutral or nearly neutral oil, and should be rejected for internal use.

THERAPEUTICS.—Croton oil is a very rapidly acting, violent drastic and hydragogue cathartic. It is chiefly used in cases of *obstinate constipation* from disease of the nervous system or from lead-poisoning. The fact that a drop of it placed upon the tongue will purge actively peculiarly fits it for use in *mania*, *delirium tremens*, and other diseases when the patient refuses to take medicine. When it is desired, as in some brain-diseases, to revulse through the bowels, croton oil is probably the most available of the cathartics. The dose is one drop, which may be administered in pill, in emulsion, or by simply placing it upon the tongue. In overdoses, croton oil is a violent poison.

TOXICOLOGY.—Although in small amounts croton oil causes such severe symptoms, yet in larger quantities it has failed to produce as serious results as would be naturally expected. It is, however, very possible that in at least some of these recorded cases the oil was adulterated. Cowan has reported a case (Husemann, *Toxicologie*, Bd. ii. p. 443) of a child, four years old, who recovered in two days from a teaspoonful of croton oil taken on a full stomach; Adams (*Ibid.*) saw recovery in an adult after the ingestion of a drachm; and in the *Boston Med. and Surg. Journ.*, 1868, i. 294, is recorded the case of a woman who took about an ounce, was vomited forty-five minutes afterwards with mustard, and finally recovered. The minimum fatal dose is not known, and probably varies greatly. A child aged thirteen months was killed by a quantity believed not to exceed three minims (*Med. Times and Gaz.*, 1870, i.). Giacomini (Stillé, *Therapeutics*, vol. ii. p. 451) reports a case in which twenty-four grains of the drug proved fatal in as many hours: although there were but four stools, the patient presented the symptoms of general collapse, preserving consciousness to the last. A little less than two drachms has caused vomiting and death without purging (*Amer. Journ. Med. Sci.*, April, 1874).*

* For other cases, see *Med. Gaz.*, vol. xliii.; *Edinb. Med. Journ.*, 1861; *Lancet*, 1870, i.; *Brit. Med. Journ.*, 1874, i.; *Ann. d'Hyg.*, 1871, i.; also Kobert's *Arbeiten*, iv., 1890.

FAMILY IV.—DIURETICS.

DIURETICS are medicines used for the purpose of increasing the flow of urine. Some of them, without doubt, act directly upon the secreting structure of the glands, but others of them induce the increased secretion indirectly, by, in some way, removing the obstacle to secretion. It is notorious that diuretics often fail in practice when their action is most urgently needed. This results, in many cases, from the nature of the disease, and is not because diuretics are powerless or uncertain. Thus, in cardiac disease the congestion of the kidneys may be so great as to render secretion impossible; and it is equally evident that when the tubules are destroyed by Bright's disease medicines must be powerless to provoke excretion.

There are certain agencies whose influence upon the kidneys should never be lost sight of in exhibiting diuretics. Thus, cold, by checking the secretion of the skin, often acts as a most efficient remedy of the class. Again, more vascular fulness tends to provoke excretion of water by the kidneys. This assertion does not rest simply upon theory. In an elaborate series of experiments, E. Roux (*Archives Physiol.*, 1874, p. 578) found that the ingestion of large quantities of water greatly increased the flow of urine, but did not sensibly affect the elimination of urea or uric acid, although the elimination of the chlorides seemed to be augmented; in Böcker's experiments, however (*Brit. and For. Med.-Chir. Rev.*, xiv., 1854), large draughts of water increased not only the amount but also the solids of the urine. The investigations of J. Meyer (*Hoffmann und Schwalbe's Jahresb.*, 1881, 345) explain these discrepancies and show how water may be of service in various diseases. He found that at times, when the tissues were full of the products of disintegration, the effect of water in increasing elimination was very marked, but that upon the wasting processes of the body the water exerted no influence. It would seem, therefore, that while we cannot by water produce tissue-disintegration, we can by it wash out the retained products of tissue-change; and I cannot help suspecting that the great rarity of uninhaerited gout in America has some connection with the universal habit of drinking water very freely. Large draughts of simple water at regular intervals often act very favorably in acute Bright's disease, greatly increasing the urinary flow, and at the same

time lessening the irritation of the kidneys. Porak and Bernheim (*Nouv. Arch. d'Obstet. e. Gyn.*, viii., 1893) claim to have obtained the most extraordinarily good results in very grave acute *Bright's disease*, especially such as occurs in pregnancy, by the hypodermic injection of a thoroughly sterilized solution of seven and a half grammes of sodium chloride to a litre of water. They inject into the abdominal walls or the buttocks as much as five hundred grammes of the liquid at one time, and have given in eight hours fifteen hundred grammes in four injections. In various inflammations or irritations of the *genito-urinary* organs, as in *gravel*, whenever it is desired to make the secretion less irritating or less concentrated, the value of water as an adjuvant to medicinal diuretics should always be taken advantage of.

There certainly is a very marked antagonism between the bowels and the kidneys, so that free catharsis reduces very decidedly the secretion of urine. There is also an antagonistic relation between the skin and the kidneys, so that an increase in the excretion from one of these generally results in a diminution of that of the other emunctory. This should also be taken advantage of when a diuretic action is desired. Sweating and purging at such times are therefore to be avoided. When a diuretic is exhibited, the patient should be kept cool, walking about if able, or if it is necessary for him to remain in bed he should be covered lightly. Not rarely, a remedy which when administered cold and the patient kept cool afterwards will act as a diuretic, will when it is given hot and the patient kept warm act as a diaphoretic.

There are various substances which are of such nature that when eliminated by the kidneys they act upon the mucous membrane of the bladder and other surfaces over which they pass. It seems hardly correct to speak of these drugs as diuretics; yet they are best considered in the present class.

The chief indications for the use of diuretics are as follows:

1. *To maintain the action of the kidneys.* It is hardly necessary here to discuss the necessity of excretion to the system. In various kidney-diseases this indication is very urgent; but as the lessened excretion too often depends upon a profound organic alteration of the renal secreting structure, it is evident that very frequently diuretics must fail when most needed. In the great majority of cases in which diuretics are used to fulfil the present indication, only the mildest of the class should be employed. Whenever there is inflammation of the kidneys, even if it be chronic, irritating diuretics should be avoided. When lessened urinary excretion is purely functional in its origin, diuretics are often most serviceable. In fevers especially it is necessary to maintain the action of the kidneys; for this purpose water should always be freely given during fever. The alkaline diuretics sometimes may be exhibited; but the most generally serviceable of all remedies of the class in the febrile state is the sweet spirit of nitro.

2. *To evacuate fluid.* For this purpose diuretics are employed in all

forms of dropsy, and are successful in direct proportion to the universality of the effusion and the structural perfection of the kidneys.

3. *To soothe and diminish irritation of the genito-urinary organs.* The value of water in fulfilling this and the next indication has already been pointed out. By lessening the acidity of the urine and rendering soluble the uric acid which is present, the alkalies are equally important in carrying out the present and the following indication.

4. *To alter the urinary secretion so as to prevent the deposition of calculous material.* Notwithstanding it has been claimed otherwise, I think it indubitable that as yet no practical measure has been devised of dissolving a calculus when once formed. Even to alter the urine so as to prevent further deposition is probably impracticable, except in cases of uric acid or phosphatic diathesis. A discussion of the use of diuretics for this purpose will be found in the article on Potash, which is the only diuretic used to meet the present indication.

Diuretics are very naturally divisible into three sets,—the hydragogue diuretics, the refrigerant diuretics, and the alterative diuretics. These classes, of course, grade more or less into one another, but they are sufficiently distinct for practical purposes. The drugs belonging to the first set simply increase the flow of water from the kidneys, and are therefore used chiefly for the relief of dropsy; those of the second division exert a marked sedative action upon the system, and generally do not increase to a great extent the water of the urine, but modify the secretion in one way or the other, and are mostly given to render the urine less irritant or for their sedative and eliminative action in acute disease. Diuretics belonging to the third division are of such nature that their active principles are eliminated by the kidneys and act upon the mucous surfaces over which they pass,—for which purpose they are chiefly employed.

HYDRAGOGUE DIURETICS.

SCILLA—SQUILL. U.S.

The bulb of *Urginea maritima*, a liliaceous plant growing in the south of Europe, especially on the shores of the Mediterranean. The bulb varies in size from that of a child's head to that of the fist. It is composed of numerous layers or scales, which separate when it is sliced for drying. As kept in the shops, squill is in horny flakes, of a white or red color, becoming leathery when wet, and having an acrid bitter taste. It yields to water and alcohol, and also to vinegar. *Scillitin* has been asserted to be the active principle of squill; but the *scillitin* of different authors is diverse. According to Reil, there are two active principles in squill, one of which he names *Scillitin*, representing the diuretic and expectorant properties of the drug, while the toxic and irritant properties reside in a substance which he calls *Sculein*; recently (*Arch. f.*

Exper. Path. u. Pharm., xi. 22) C. V. Jarnersted* has described a new principle from squill (*Scillain*), and Merck has sold three substances as derived from squill,—*Scillin*, *Scillipierin*, and *Scillitoxin*.†

PHYSIOLOGICAL ACTION.—According to the experiments of Chateau (quoted by Stillé) and of Marais, squill in poisonous dose produces in dogs and other of the lower animals vomiting, then purging, dulness, stupor, intermittent paralysis, convulsions, and finally death in the course of twelve or fifteen hours. The temperature always falls. Professor Schroff (*Wochenblatt der Zeitschr. der k. k. Gesellsch. zu Wien*, 1864, p. 424) has reinvestigated this subject, using alcoholic extracts of the red and white squill, and also the scillitin of Merck. Fifteen grains of the latter caused in a vigorous rabbit great weakness, mydriasis and, after an hour or so, tremors gradually becoming violent, partial stupor, labored breathing, and finally death; twenty-three grains caused in another rabbit sinking of the pulse- and respiration-rate, mydriasis, diuresis, and death, preceded by the other symptoms noted in the previous case. The alcoholic extract (fifteen grains) caused (*loc. cit.*, 424) in a large rabbit decrease of the number of respirations per minute, with rise of the pulse-rate, narrowing of the pupil, semi-stupor, and finally death. On post-mortem examination of rabbits killed with the scillitin, erosion of the gastric mucous membrane, pericardial and sub-pleural hemorrhages, pulmonary apoplexy, bloody urine, and hyperæmia of the kidney and brain were found. In rabbits destroyed by the extract, gastric erosion and the various hemorrhages were wanting. It seems evident that the scillitin of Merck does not represent squill. In a memoir, which I have seen only in abstract, Dr. Husemann states that the extract of squill has no expectorant properties, that it acts on the heart like digitalin, that its diuretic powers are dependent upon its action on the circulation, and that both in large and in small doses it uniformly produces a rise of temperature (*Deutsche Med. Wochens.*, No. 13, 1875; abstracted *Lond. Med. Rec.*, 1876, p. 120). Husemann also finds commercial scillitin very uncertain. These statements receive confirmation, at least in part, from the researches of C. Lupinski, who has found that scillitoxin is a powerful stimulant to the peripheral vagi in the frog, causing slowing of the pulse, and in certain doses diastolic cardiac arrest, and in the dog slowing of the heart. Large doses cause in the frog tetanic contractions of the heart. He also found that in the dog large doses finally

* Jarnersted states that his scillain increases, and afterwards diminishes, blood-pressure, causing vomiting and purging, and finally paralyzes the heart-muscle.

† Dr. Fronmüller has reported (*Memorabilien*, 1879, xlv. 250) a series of experiments made, upon persons suffering from various ailments, with the scillin, scillipierin, and scillitoxin of Merck. He found that scillitoxin in doses of 0.45 grain acted as a rather uncertain diuretic, and frequently caused giddiness, headache, and loss of appetite; scillin seemed to be devoid of diuretic properties; while a gramme of a solution of scillipierin in water (one part in fifty) administered hypodermically usually caused a great flow of urine, without other evil symptoms than some smarting at the place of injection.

paralyze the peripheral vagi and produce a rapid pulse. The arterial pressure is increased, partly, it is affirmed, by the increased cardiac energy, and partly by a peripherally-produced vaso-motor contraction (*Hoffmann und Schwalbe's Jahresh.*, 1883, 123; from the Russian).

Clinical experience has established the fact that in small repeated doses squill is diuretic as well as expectorant. The remedy is evidently a stimulant to the kidneys, and in overdoses causes an irritation whose result is lessening of the secretion, scanty bloody urine, or absolute suppression of urine, according to the ingested dose of the poison. Its diuretic action has been noted in animals by Schroff and by Chiarenti (quoted by Stillé), and there can be no doubt as to the power that squill has of increasing the watery portion of the urine. I know of no studies upon its action on the urinary solids.

That the active principles of squill are absorbed is proved not only by its action on the kidneys, but also by the fact that its characteristic effects on the system have been seen to follow its external application (See Stillé, *Therapeutics*, 2d ed., vol. ii. p. 534.)

THERAPEUTICS.—As a diuretic, squill is in great repute, and is especially employed in cases of dropsy where the condition of the system is atonic and where there is no disease of the kidney. Professors Geo. B. Wood and Chapman recommend it very strongly in cases of *serous effusion* into the *pleura* or the *pericardium* dependent upon chronic inflammation of the membrane. In these cases it may often be advantageously combined with calomel. The combination of squill and digitalis is very efficient in *cardiac dropsy*. The one contra-indication to the use of squill is the existence of any form of Bright's disease or of acute irritation of the kidney.

TOXICOLOGY.—Overdoses of squill produce violent purging and vomiting, with abdominal pain, lessened or almost suppressed secretion of bloody, albuminous urine, and very marked reduction of the pulse-rate, ending, it may be, in collapse, convulsions, and death. According to Husemann (*Toxicologie*, Bd. i. p. 413), twenty-four grains of it have brought about a fatal result. The treatment consists in the evacuation of the stomach and bowels by ipecacuanha and castor oil, if nature has not already fulfilled the indication; the free use of opium; the exhibition of large quantities of water, for its action on the kidneys; and the usual measures for the relief of gastro-enteritis, if much tenderness be present. Early in the poisoning care should be exercised in the exhibition of alcoholic stimulants, for fear of increasing the gastric irritation; during the stage of collapse they may be imperatively demanded, and with their use should be combined that of dry heat applied externally, and of the other usual measures of relief during collapse.

ADMINISTRATION.—As a diuretic, squill should be given in solid form, two grains every two hours, the dose being gradually increased until some nausea is felt. The preparations of squill are the *tincture*

(*Tinctura Scillæ*—15 per cent., U.S.).—dose, \mathfrak{xx} to \mathfrak{xxx} ; the *vinegar* (*Acetum Scillæ*—10 per cent., U.S.).—dose, \mathfrak{xx} to \mathfrak{xxx} ; the *syrup* (*Syrupus Scillæ*, U.S.).—dose, \mathfrak{ss} to \mathfrak{ss} i; the *fluid extract* (*Extractum Scillæ Fluidum*, U.S.).—dose, \mathfrak{i} to \mathfrak{iii} .

DIGITALIS, in its general relations, has already been sufficiently discussed, and it remains only to speak of its employment as a diuretic. In the first place, it should be distinctly understood that it has no alterative effect whatever, either upon the nature of the secretion or upon the mucous membrane over which that secretion flows. In other words, when it has any effect it is purely a hydragogue diuretic, simply increasing the watery portion of the urine. That digitalis has direct diuretic properties cannot, I think, be doubted. Nor does it seem less certain that it varies greatly in their exercise, so that when given to persons in health it will sometimes produce free diuresis and will at other times fail to do so. Another point to be constantly borne in mind during its administration is the fact that, like all the other effects of digitalis, diuresis is very slowly induced, and is very persistent when produced by the ordinary cautious method of administration. The diuresis of digitalis is not simply a result of its action on the circulation, since it will sometimes appear before the circulation is sensibly affected. At the same time, it is very evident that in disease the good effect of digitalis upon the renal organs is often in large measure due to its action upon the heart. Thus, in dropsy from a dilated heart the renal gland-cells cannot secrete because they are not supplied with the proper kind and quantity of blood, their circulation, like that of the remainder of the body, being nearly stagnant. If under these circumstances digitalis be exhibited, and the circulation becomes comparatively free and active, the resultant diuresis is wrought out through a double mechanism, partly indirectly and partly directly produced by the drug. As a consequence of these facts, the clinicians have long since practically determined that digitalis is especially valuable as a diuretic in *cardiac dropsy*. Digitalis is also very useful in *renal dropsy*, both in the subacute and in the chronic form. Of course, like everything else, it frequently fails in these varieties of Bright's disease, but certainly it should always be tried. Professor George B. Wood asserts that he has seen cases of "what appeared to be decided and obstinate attacks of Bright's disease, with universal dropsy, and unconnected with scarlatina, which yielded completely and permanently to the use of digitalis." In *acute suppression of urine*, digitalis is often a very valuable remedy when applied externally, especially when the stomach refuses to retain medicines. At the same time, it should be remembered that large doses of the drug used in this way sometimes induce very alarming symptoms. Flannels saturated with the tincture may be applied to the abdomen, or poultices of the leaves may be similarly used. Dr. Lente (*Psychol. and Med.-Leg. Journ.*, 1875) says

that he has been accustomed to use, even in children, four ounces of the best English leaves, and with a quart of water "make a poultice which extends all round the body, and from the thorax to the pelvis." Only in desperate cases is such heroic use of the remedy warrantable. Dr. E. F. Fannell has seen (*Brit. Med. Journ.*, March 11, 1871) almost fatal collapse produced by the external use of an ounce of the tincture in a case of renal dropsy.

ADMINISTRATION.—The dose of the powder of digitalis, as a diuretic, is three grains a day (in divided doses), increased by a grain every second or third day, until some sensible effects are manifested. The infusion or the tincture may be substituted for the powder, in corresponding dose. Digitalis, in the majority of cases, is best given in combination: in cardiac dropsy it is much more efficient if given with squill; in renal diseases the bitartrate of potassium may be exhibited simultaneously. While our present knowledge of the physiological action of digitalis is in accord with the ascertained clinical fact that it is safe to give the drug cautiously in the last stages of cardiac exhaustion, yet it should never be forgotten that, as a diuretic, digitalis sometimes refuses to act, and that it is possible to produce the most profound depression with it without inducing the desired result. It is, therefore, worse than useless to persist with the medicine to the danger of the patient after its constitutional effects have been distinctly produced and no diuresis has occurred. The diuretic external use of digitalis is made by putting a poultice of an ounce of the fresh leaves upon the abdomen of the patient, or, preferably, flannel cloths wrung out of the infusion may be applied to the same part and covered with oiled silk, or half an ounce to an ounce of the tincture may be sprinkled upon previously-moistened spongiopilin. In either case the application should not be allowed to stay on for more than eight hours, at the expiration of which period it should be removed, to be replaced at the end of six hours if no effect has been produced.

SCOPARIUS—BROOM. U.S.

Scoparius is the dry tops of *Cytisus Scoparius*, or the common broom-plant of Europe, which is cultivated in this country and has in some places escaped from the gardens. It occurs as greenish twigs, with minute downy leaves, has a bitter nauseous taste, and, when bruised, a peculiar odor, and yields its virtues to hot water. Dr. Stenhouse discovered in scoparius a neutral crystallizable principle, *Scoparin*, whose physiological and therapeutic action has not been sufficiently investigated in order for us to arrive at a positive conclusion, but which appears to represent the purgative and diuretic influences of the drug; also a liquid alkaloid, *Sparteine*,* which has already been discussed under the head of Cardiac Stimulants.

* *Oxysparteine*, an oxidation product from sparteine, was discovered by F. Abrens (*Berl. Chem. Ber.*, 1891) and investigated by K. Hürthle (*Arch. f. Exper. Path. u. Pharm.*, 1892).

In very large doses, *scoparius* produces in man free purging, and even vomiting; but as ordinarily administered it is simply a most efficient hydragogue diuretic. It is much used in general dropsy, and is one of the most reliable remedies of the class, seldom failing unless the structural lesions are such as to prevent any diuretic from acting. It is best given in decoction,—half an ounce of the tops in a pint of water boiled down to half a pint. Of this an ounce may be given every three hours until some effect is produced; or a fluid extract, which is not official, may be given in half-drachm doses.

CALOMEL as a Diuretic.—Many years ago therapeutic writers, notably Dr. George B. Wood, claimed that the combination of digitalis, squill, and calomel yields in the treatment of dropsy, and especially of cardiac dropsy, diuretic results much superior to either of the vegetable products alone; but to Dr. E. Jendrassik (*Deutsch. Archiv Klin. Med.*, Bd. xxxviii., 1886) belongs the special credit of directing the attention of the profession to the great practical value of calomel as a diuretic. The paper of Jendrassik has been followed by numerous articles.*

The method in which the calomel acts may be variously explained. Dr. Noel Paton (*Brit. Med. Journ.*, ii., 1886) believes that the mercury increases the formation of bile secretion and of urea. If this be so, the increased production of urea naturally provokes increased diuresis. Dr. W. Cohnstein (*Archiv f. Exper. Pathol.*, xxx., 1892) has found that the hypodermic injection of mercurial solutions produces a very quick and active diuresis in the rabbit, and the mercury almost certainly acts directly upon the cells of the kidneys. According to Drs. Brasso and Wirth (*Compt.-Rend. Soc. Biolog.*, 1887), when mercury is given hypodermically in large dose it soon appears in the urine, which is markedly increased in quantity; if, as not rarely happens, the urine becomes albuminous, excretion of mercury at once ceases, albumen and mercury never co-existing in the urine. Dr. Silva (*Centralb. Klin. Med.*, ix., 1888), experimenting with defibrinated blood, finds the addition of a mercuric salt causes the kidney vessels to dilate, the local blood-pressure to rise, and secretion to increase. Moreover, it is certain that mercurials in excess cause desquamative nephritis; so that it must be concluded that these preparations either stimulate or irritate the renal secretory structure according to the amount present.

All preparations of mercury appear to share in the diuretic influence, but Bieganski has found that the effect is most active after subcutaneous injections, and least so after inunctions.

It is said to be a very active cardiac stimulant. The hydrochlorate is freely soluble in water, and has been used with asserted good results hypodermically by Dr. Von Oefele, in dose of six-tenths of a grain. The heart is said to become rapidly accustomed to its use.

* See Dr. T. Jones (*Brit. Med. Journ.*, ii., 1888), Dr. Wladyslaw Bieganski (*Deutsch. Klin. Med.*, Bd. xliii., 1888), Dr. R. Stintzing (*Ibid.*), I. Pal (*Centralb. f. Ges. Therap.*, 1890), and W. E. Ignatzew (*St. Petersburg. Med. Wochens.*, 1888).

In practice it has been found essential to give the mercury in full doses. Dr. Jones administered six grains of calomel a day; Dr. Jendrassik as much as nine grains a day, continuing the treatment from three to twelve days. As purgation interferes with diuresis, it is sometimes necessary to guard with opium. Bieganski affirms that disease of the kidneys prevents the diuretic action of the mercurials, but Von J. Sktodowski (*Schmidt's Jahrb.*, Bd. cccxxv., p. 231) claims that calomel in chronic *parenchymatous nephritis* is especially valuable because it does not irritate the renal epithelium, and in most of the cases is very efficient. Dr. Fleiner (*Schmidt's Jahrb.*, Bd. cccxx.) also highly commends calomel in advanced *Bright's disease*, and I have myself seen it act most powerfully and beneficially.

In *cardiac dropsy* the treatment is often very efficacious. The general system is often much benefited; the sleep, appetite, and digestion rapidly improving. I have myself seen very good effects from the long-continued use of minute doses of mercurials in chronic cardiac affections without dropsy, results which I have attributed to the action of the drug upon the digestive organs.

THEOBROMINE.—Theobromine is a crystallizable alkaloid, which forms very bitter salts which are mostly dissolved with difficulty. Under the name of *diuretin* a more or less impure theobromine and sodium salicylate has been introduced into medicine. It is a white powder, soluble in less than half its weight of warm water. The pure *sodium* and *theobromine salicylate* should contain about forty-nine per cent. of theobromine: the commercial article, according to various analyses, has in it from thirty to forty-eight per cent. In 1890 the attention of the profession was called by Dr. C. Gram (*Therap. Monatsh.*, iv., 1890) and by Kouindig-Pomerantz (*Bull. Thérap.*, 1890) to the value of theobromine and sodium salicylate as a powerful and practical diuretic; but our knowledge of the intimate physiological action of the remedy is still very limited.

Dr. Ivan M. Sabashnikoff (*St. Petersburg Inaug. Diss.*, 1892; *Pror. Med. Journ.*, 1892) states that the toxic dose of diuretin produces free salivation, vomiting, and diarrhoea, as well as free diuresis. The same authority affirms that the respiration is quickened by the small dose, whilst the large dose causes an intense dyspnoea, with elevation of bodily temperature which sometimes amounts to four degrees centigrade, but is prevented by previous high section of the spinal cord. Upon the striated muscles the action of the drug is said to be similar to that of caffeine. The Russian observer has further found that a large dose of diuretin sharply increases the irritability of the motor area of the cerebral cortex, and although under its influence the cardiac beats become first slower and then in a little while more frequent and more energetic, the arterial pressure sinks from the beginning. Cohnstein (*Inaug. Diss.*, Berlin, 1892) also has noticed the fall of arterial

pressure after the toxic dose of diuretin, but states that the ordinary dose has no perceptible influence upon the heart and blood-vessels.

Sodium and theobromine salicylate has been much used as a practical diuretic, the general professional verdict being that it has direct influence upon the renal secreting structure, that it is non-irritating to the kidneys, and rarely causes disagreeable symptoms. It has been especially recommended in *cardiac dropsy*, and it is claimed by various practitioners that when the heart is weak it has a direct and immediate influence in increasing the arterial pressure and favorably regulating the cardiac beat (Masius, also Pawinski, *Gazeta lekarska*; Vrach, 1893). Professor Demme, of Bern (*Am. Pract. and News*, 1892), states that it acts very well on children, and that in acute scarlet fever *nephritis*, with a high grade of dropsy, it is the best known remedy: various practitioners have commended it in *chronic nephritis*. In rare cases it has acted unfavorably, causing headaches, irregularity of the pulse, vomiting, diarrhoea, and even—according to W. Schmiedon—haematuria. From forty to one hundred and twenty grains may be administered during the course of the day, in capsules or solution, or hypodermically. According to Demme, to a child six years old twenty to thirty grains may be given in the twenty-four hours.

BLATTA.—The dried bodies of the *Blatta orientalis*, or cockroaches, have long been popularly used in Russia as a remedy for *dropsy*. Bogomolow found in them a crystalline principle which he called *Antihydro-pin*.* Under their influence the sweat and urine are said to be greatly increased and the dropsy rapidly to disappear. When the urine contains albumen, this is greatly lessened or disappears entirely. The proper dose is uncertain. Bogomolow (*Lond. Med. Record*, 1877, p. 502) gives four and a half grains three times a day to children. Probably fifteen to twenty grains daily is about the proper commencing dose for the adult.

SPIRITUS ÆTHERIS NITROSI, U.S.—*Sweet Spirit of Nitre* will be considered in the class Diaphoretics, in detail. Suffice it for the present to state that when given in a single large dose (a teaspoonful to a table-spoonful) and the patient afterwards kept cool, sweet spirit of nitre acts as a moderately efficient diuretic, increasing the watery portion of the urine, but not to such an extent as to render the drug available for use by itself in dropsy. It acts upon the kidneys as a mild, soothing stimulant, and is mostly employed as an adjuvant to more powerful

* J. Tschernischew (*Schmidt's Jahrb.*, exvii. 205) states that he has found in the cockroach a very powerful poison, *Blattic acid*, which produces in frogs paralysis of the heart and motor nervous system. In the inammal small doses slow the pulse without affecting the vagi, while large doses paralyze the vagi and increase the pulse-rate. The blood-pressure is reduced by a direct action upon the vaso-motor centre. The secretion of urine is increased from five- to ninefold by even moderate doses.

diuretics, or by itself when there is simply diminished renal excretion of functional origin, or when the kidneys suffer from slight congestion, as shown by aching in the loins without other more serious symptoms.

Jaborandi, *Digitalis*, *Strophanthus*, and *Caffeine* are all active and powerful diuretics. (For discussion of each, the reader is referred to the respective articles upon the subject.)

Sugar as a Diuretic.—In the last few years it has been claimed by Drs. S. Meslach, Zavadsky, Professor Germain-See, and other clinicians, that both glucose and the sugar of milk are active hydragogue diuretics, which may often be advantageously used in the treatment of *cardiac dropsy*, *pleuritic effusions*, etc., but are of little value when there is renal disease. The general testimony seems to be that the sugar of milk is the more active of the two. These sugars may be given in doses of from one to six ounces a day, administered in concentrated syrup or in milk. How sugar under these circumstances acts as a diuretic, or whether it has any influence upon the nervous system and circulation, is at present doubtful. According to the experiments of Albertoni, all sugars injected into the veins cause a rise of the arterial pressure by a direct stimulation of the heart. He also found that the kidneys, as tested by Roy's oncometer, become congested or swollen.

REFRIGERANT DIURETICS.

POTASSIUM. (K.)

The salts of potassium,* like the substance itself, are very poisonous to the lower animals. According to Dr. Paul Guttman, they are all exactly alike in the character and the intensity of their action; but further experimentation is wanting before this point can be considered as decided, and I have preferred to study the bromide entirely separate from its congeners.

In the experiments of Podocaeppow (*Virchow's Archiv*, 1866, Bd. xxxv. p. 460) it was found that one cubic centimetre of a solution of the chloride (one to five), given to a frog by the stomach, would in

* The preparations of the alkaline metals are used in practical medicine for such different purposes that these metals are widely scattered in the present treatise. As insisted upon by Binet, however, they have much in common; dividing themselves naturally into two groups, one containing lithium, sodium, and potassium, characterized by producing general paralysis with the arrest of the heart in diastole; the second group, calcium, strontium, and barium, characterized by their tendency to produce, along with the loss of motor power, muscular contractions (especially barium), and by their arresting the heart in systole. Magnesium approaches the first group by arresting the heart in diastole, but separates itself by its extreme tendency to paralyze the peripheral nervous system. The law enunciated by Rabuteau, that there is a consistent relation between the toxicity of the metal and its atomic weight, appears not to be correct.

eight minutes cause abolition both of voluntary and of reflex movements. After from fifteen to twenty minutes, cardiac arrest occurred. Upon mammals similar results were obtained, but the abolition of motility was apparently not so profound as in the frog. Thus, four or five drachms of potassium chloride injected into the stomach of the dog caused bloody stools, reduction of temperature, muscular weakness, and death without convulsions. Although in most, if not all, of the reported cases of poisoning by potash salts, the most prominent symptoms are those due to the local action upon the alimentary canal, yet it would seem that poisonous doses act upon man as upon other mammals, as great feebleness of pulse and lowering of temperature have been noted as constant phenomena.

Circulation.—The most marked action of the potash salts is upon the heart. When a frog is killed by a salt of potash, the heart* is arrested in diastole, according to both Podocæpow† and Guttman. The blood-current before death is greatly lessened in force, as was determined by Podocæpow by watching the circulation in the web, and by comparative experiments in regard to the rate at which blood flowed from wounded vessels in poisoned and in unpoisoned frogs. In mammals, potash influences the heart even more markedly than in cold-blooded animals. Ten or fifteen grains of the chloride quickly injected into the jugular vein suffice to produce instant cardiac death. According to Aubert and Dehn (*Pflüger's Archiv*, 1874, p. 122), for a few seconds before complete suspension of movement there are irregular, "stormy" convulsions, which run through the heart in a sort of peristaltic manner with great rapidity, but have no effect in expelling the blood. A curious fact discovered by Aubert and Dehn is that the effect of the potash is not permanent unless it has continued a certain length of time. Thus, a hound received into its jugular a fatal dose of potassium chloride, and ten seconds after all pulsations had ceased the crural artery of a second dog was connected with the jugular of the poisoned animal, when the heart recommenced its movements, only to cease again after a time. The action of a poisonous dose of potash upon the heart appears to be a local one. Traube found that when death in the dog was produced by injection into the jugular the heart-muscle failed entirely to respond to electricity. In this case, however, the heart received at once the full dose of the poison, and the careful experiments of Podocæpow and of Guttman have shown that when the potash is introduced gradually and in the more ordinary

* The poisonous influence of potash upon the heart was, I believe, first discovered by Black (*Comptes-Rendus*, 1839), and has been confirmed by Bouchardat (*Annuaire de Thérapeutique*, 1844), by Grandeau (Robin's *Journal de l'Anatomie*, 1864), by Rabuteau (*L'Union Médicale*, 1871), and by others.

† *Virchow's Archiv*, Bd. xxiii. It is proper to mention that Podocæpow states on p. 506 that the arrest is sometimes systolic, sometimes diastolic, although on p. 511 he asserts that the arrest never occurs in systole.

methods into the circulation, the contractility of the cardiac muscle, although very much impaired, is not at the time of death entirely destroyed; in frogs it is less affected than in warm-blooded animals. Guttman has found that previous section of the vagi has no influence upon the action of large doses of potash, which therefore cause diastolic arrest by a direct impression upon the cardiac muscle. This cardiac action of the potassium salts is in fact only a portion of the wide-spread general influence upon the muscles, as Dogiel (*Central. f. d. Med. Wissen.*, 1892) has found that the heart-muscle is simply more sensitive to the action of the drug than are the muscles of the intestinal walls and of the skeleton.

Although the effects of large doses of compounds of potassium on the heart appear to be made out, definite knowledge is still wanting in regard to small doses. Traube (*Gesammelte Beiträge*, Bd. i, p. 386) asserts as the result of his experiments that, injected into the blood in doses of two or three grains, the potassium nitrate produces a fall in the pulse and a rise in the arterial pressure. Aubert and Dehn (*Pflüger's Archiv*, 1874, p. 126) have experimented with a number of the salts of potash, and found that, with the exception of the permanganate, they all act upon the circulation in the manner just described. If larger doses of the potash preparations were employed, the rise was preceded by a temporary fall of pressure, and if the doses were still larger, the fall was permanent. The first fall of pressure, as well as the permanent impression produced by large doses, was probably caused by the direct action of the drug upon the heart-muscle. The cause of the rise is still enveloped in obscurity, as is also the manner in which potash affects the pulse-rate. Traube affirms that if the vagi be cut after exhibition of the potash salt, the lessened pulse-rate instantly becomes rapid, and the already increased arterial pressure rises still further. The same observer also found that after section of the pneumogastrics small doses of the nitrate produced a fall in the pulse, with increased arterial pressure; but on a repetition of the dose in the same animal no lessening of the pulse-frequency was perceptible, while each time the pressure rose. This seems to indicate that the cardiac action of the drug is independent of the inhibitory apparatus, which is confirmed by the experiments of Aubert and Dehn (*loc. cit.*, p. 145) upon atropinized dogs. It is very probable, but not in any way proved, that the rise of pressure is brought about through the vasomotor nerves. Both Podocapow (*loc. cit.*, p. 615) and Aubert and Dehn (*loc. cit.*, p. 150) have called attention to the very temporary effect of the potash injections: thus, after small doses the arterial pressure returns to its normal position in three minutes; after large doses the maximum effect is reached in ten minutes. Aubert and Dehn also assert that there is no cumulative action, many small doses given at brief intervals leaving no residual effect; but this is in direct opposition to the statements of Guttman. Köhler affirms that after section

of the spinal cord potash salts have less influence upon the heart, and that larger doses are required to kill (*Centralbl. f. Med. Wiss.*, 1877, p. 675). The only fixed conclusion warranted by the evidence is the absolute necessity of further investigation. Mairct and Combemale assert that even after moderate doses of potassium nitrate changes can be seen in the red blood-corpuscles, which become granulated and some of them larger than normal (*Comptes-Rendus Soc. de Biolog.*, 1887, vol. iv. pp. 57 and 63).

Muscular and Nervous Systems.—The action of the drug upon the motor system is more marked in cold- than in warm-blooded animals. Podocæpow believes, but does not definitely prove, the paralysis of both voluntary and reflex movement to be of muscular origin. The much more elaborate experiments of Guttmann show that the muscles of poisoned frogs are not only excitable at the time of death, but are nearly as sensitive as normal muscles, and maintain their excitability nearly as long after death. As both nerve-trunks and muscles are capable of performing their functions in the dying frog, Guttmann concludes that the paralysis is of spinal origin, a conclusion which he confirmed by tying the aorta directly above its bifurcation and then administering the potash, when the paralysis appeared as early in the protected hind legs as in the non-protected front ones.

By an elaborate series of experiments, Drs. Ringer and Murrell have shown that the potash salts, in sufficient concentration, act powerfully upon the cerebrum, the motor and sensory nerves, and the muscles; in a word, that they are *poisonous to all the higher forms of tissue*. In poisoning, however, the brain and spinal cord are paralyzed much more quickly and deeply than are the peripheral nervous and muscular tissues; consequently, in general poisoning the symptoms are produced through the higher nerve-centres (*Journal of Physiology*, i. 88; see also Limbourg, *Arch. Exper. Pharm.*, 1888, xxiv.). All of the potash salts probably act in a similar manner * as depressants of the spinal cord, their power, according to the experiments of Ringer and Morshead (*Journ. Anat.*, xii. 82), being in direct proportion to the amount of potash they contain.

General Influence.—Outside of the body, potash favors very greatly the oxidation of organic substances. Thus, when olein is exposed to ozone no change occurs, but if potash be added rapid oxidation follows. Again, when albumen or hæmatin is dissolved in water no change, or a very slow one, occurs, but if potash be added the organic principle is oxidized with extraordinary rapidity. Whether a similar influence is or is not exerted within the body is not as yet completely determined, but the present evidence strongly indicates that it is.† The fall of tem-

* Ringer and Murrell, applying the chlorides, iodides, and bromides of potassium and ammonium directly to the ends of the afferent nerves, found that they paralyzed, the effect of the potassium being much the most powerful and permanent, that of ammonium the next, and that of sodium the least (*Journ. Anat.*, xii. 71).

† Lehman was, I believe, the first to originate the oxidation theory.

porature produced by poisonous doses of potash salts would seem to point to lessened oxidation, but is probably simply the result of the profound depression of the circulation. The chief arguments in favor of the theory of increased oxidation in the system as yet brought forward have been drawn from the studies of the action of the drug upon the urinary excretion in health and in disease. Potash and its salts administered in sufficient quantity, under ordinary circumstances, not only increase the watery portion of the urine, but, as Professor E. A. Parkes and others have demonstrated, they do more. In an elaborate series of experiments upon himself, Professor Parkes found (*Brit. and For. Med.-Chir. Rev.*, 1853, xi. 258) that liquor potassæ (fʒii) when taken fasting produced in from thirty to ninety minutes an increased flow of slightly acid urine containing the whole of the alkali and organic matter, which differed in quality from that ordinarily found in urine, and was also larger in amount than normal. An organic acid, certainly neither uric nor hippuric, was believed to form a part of the solid matter by Parkes, who attributes the alteration of the urinary solids to the oxidizing influence of the potash. Taken after meals, the liquor potassæ acted simply as an antacid, and had no perceptible effect upon the urine. Both potassium acetate and nitrate in Parkes's experiments failed to act on the urine, probably because taken in too small doses, for it is a fair presumption that their oxidizing influence is less than that of potash itself. Certainly other experimenters have found that they do influence the urinary excretion. Golding Bird found (*On Urinary Deposits*, 2d Amer. ed., 1859, p. 356) that in a case carefully tested, under favorable circumstances, three drachms of potassium acetate increased the solids of a dog's urine from four hundred and sixteen to seven hundred and eighty-two grains, or, deducting all the eliminated potash, to over six hundred grains. The increase of the uric acid was about thirty-two per cent.; of the urea, about sixty per cent.; of extractives, including kreatine, kreatinine, etc., about twenty per cent., or, speaking absolutely, the uric acid was increased eighty-five grains, the urea seventy-two grains, and the extractive thirty-six grains. Rabuteau (*L'Union Méd.*, 1871, p. 389) found that the daily ingestion of seventy-five grains of potassium chloride caused an increase of twenty per cent. in the amount of urea discharged. Aug. Dahn has also experimentally found that the potassium salts greatly increase the elimination of urea (*Pflüger's Arch.*, xiii. 368).

The various studies which have been made as to the action of the potassium salts in disease seem to bear out the oxidation theory. In six observations upon subjects affected with what may be termed indifferent diseases, such as lead-palsy, Parkes (*Brit. and For. Med.-Chir. Rev.*, 1854, xiv.) found that the urea was increased, and also the sulphuric acid, by the use of drachm doses of liquor potassæ. Dr. Austin Flint (*American Med. Monthly*, Oct. 1860) has studied the effect of the potassium nitrate upon a number of persons suffering from various

diseases, and found that it very greatly increases the amount of solids in the urine. In rheumatism Professor Parkes found that the liquor potassæ increased the elimination of sulphuric acid, but had no decided influence on the uric acid. He, however, used such small doses of the drug as not to get the effect obtained in the alkaline treatment of the disease, since he expressly states that the urine remained acid (*Brit. and For. Med.-Chir. Rev.*, 1854). Rheumatism, gout, and the uric acid diathesis certainly bear some relation with one another. It has long been customary to use potash salts in excess of uric acid in the urine, and the relief obtained has been believed to be due to the conversion of the acid into a urate. Dr. Basham affirms (*Practitioner*, 1870, vol. v.), however, that as the result of a series of analyses he has found that in uric acid diathesis not only is there a great increase of the urea during the use of potash, but also that the uric acid, either free or combined, in the urine is greatly diminished. Dr. Basham, remembering that Mr. Schunck had proved that, under the oxidizing power of potash, uric acid outside of the body is converted into oxaluric acid, which in its turn is readily metamorphosed into oxalic acid and urea, carefully examined the urine of gouty patients taking the potash, and found that not only was the urea increased, but that oxalic acid also appeared as the uric acid decreased, and that the urine, on standing, deposited crystals of calcium oxalate, although none of these could be found in it when first voided. This research of Dr. Basham certainly seems to demonstrate that in uric acid diathesis the potassium salt increases the oxidation and the ultimate metamorphosis of tissue. Where this occurs, whether in the blood, in the kidney, or in the urine itself, is not at present determined.

Rabuteau, in his experiments with the chlorido, found that the urine maintained its acidity. It is notorious, however, that large doses of the potassium acetate, carbonate, or citrate produce alkalinity of the urine. The explanation of the apparent contradiction is that the vegetable salts are destroyed in the system and eliminated as alkaline carbonates, while the nitrate, and probably chloride, sulphate, and similar compounds, pass entirely, or in great part, unchanged through the body. A proof of the latter fact is furnished by Professor Alfred S. Taylor (*Guy's Hospital Reports*, 1863, p. 177), who from the urine of a patient taking two hundred and seventy grains of the nitrate daily obtained 1587 grains of the ingested salt per diem. A portion of the potash salts escapes through the intestines, as Dr. Kramer (*Annales d'Hygiène Publique et de Méd. Lég.*, vol. i., 1843) has found the nitrate in the feces of animals taking it; and it is much more probable that the nitrate not accounted for in Dr. Taylor's investigation was eliminated by the intestines than that it was decomposed in the system. If, as there is much reason to believe, a vegetable acid when given alone passes through the system in great measure unchanged, while, as asserted by Dr. Münch (*Archiv des Vereins für gemein. Arbeiten*, 1863, p. 370), and as seems to

follow from the facts already brought forward, the same acid is found when combined with an alkali to be oxidized and converted into carbonic acid, there is in this strong corroboration of the belief that the *potash salts increase oxidation in the system*. Putting all the evidence together, it seems to me that the oxidation theory must be accepted as exceedingly plausible and probable, although not, perhaps, absolutely proved.

When a potassium salt is given in large doses for a long time, it produces a condition of dyscrasia, with impoverishment and excessive fluidity of the blood. How or why it has this action is unknown, as indeed is the exact nature of the changes. Very probably there is some connection between these changes and the oxidizing power of the drug; but any theory in the present imperfect state of our knowledge could at best be only an ingenious speculation.

Our knowledge of the physiological action of the potassium salts seems to show that the vegetable salts and the carbonates are equivalents, but that the mineral salts are more or less peculiar and individual; and clinical experience confirms this. There is, however, one exception: potassium bitartrate appears to act differently from the other vegetable acid salts, and, although direct proof is wanting, probably is not decomposed in the system. Potash itself is never used to affect the system, on account of its irritant properties; and its local action will be discussed under the headings of Escharotics and Antacids. I shall here group together all the potassium vegetable salts, except the bitartrate.

POTASSII CARBONAS. U.S.

The potash of commerce, obtained from wood-ashes and other sources, occurs in the form of fused, stony masses, variegated in color, and of a caustic, burning taste; when purified so as to form *pearlash*, it becomes of a bluish-white color. When further purified so as to conform with the officinal tests, it occurs as a coarse, granular, whitish powder, very deliquescent, soluble in its weight of water, insoluble in alcohol. It should contain only traces of the sulphate, chloride, and silicate of potassium.

POTASSII BICARBONAS, U.S.—*Potassium Bicarbonate* is manufactured by passing carbonic acid gas through a solution of the carbonate in distilled water. It occurs in transparent, colorless crystals, not deliquescent, slightly alkaline to the taste and to test-paper. It dissolves in 3.2 parts of water at 59° F., but is insoluble in alcohol.

Therapeutically the carbonate and bicarbonate are of equal value, excepting in that the carbonate is more irritant than the bicarbonate, and is therefore not so well borne by the stomach. On account of its nauseous taste, even the bicarbonate is often not so available as is the acetate or the citrate. The full dose of the bicarbonate is half an ounce daily, given in diluted solution.

POTASSII CITRAS, U.S.—*Potassium Citrate* is a whitish, granular, deliquescent salt, of neutral or very slightly acid reaction, freely soluble in water. It is the least offensive to the palate of all the potassium salts, except the tartrates. *The Solution of Potassium Citrate (Liquor Potassii Citratis, U.S.,—Potassium Bicarbonate, 123 gra.; Citric Acid, 92 gra.; Water, 3 f℥) and the Neutral Mixture (Mistura Potassii Citratis, U.S.,—Lemon-juice, Oj; Potassium Bicarbonate, enough to neutralize) have been long used as diaphoretics in sthenic fevers. The dose is half a fluidounce to one fluidounce every one or two hours. A very elegant method of exhibiting neutral mixture is in the form of Effervescing Draught. It is especially useful when there is any tendency to sick stomach. It should be prepared in two solutions: one consisting of lemon juice and water, equal parts, or of citric acid ℥ii, water f℥iv; the other of potassium bicarbonate ℥i, water f℥iii. An ounce of each of the solutions is to be put together and drunk during effervescence.*

POTASSII ACETAS, U.S.—*Potassium Acetate* is a perfectly neutral white salt, of a decidedly saline taste, extremely deliquescent, and soluble in half its weight of water. It is made by dissolving the bicarbonate in acetic acid, and evaporating. It occurs sometimes as soft, fibrous masses, at other times it has a foliated structure.

THERAPEUTICS.—An important use of the vegetable salts of potassium is in *acute inflammatory rheumatism*. Before the introduction of the salicylates the alkaline treatment was the best that was known for cases of thoroughly *acute rheumatism*: the medicine must be given freely, an ounce to an ounce and a half in the day, and be persisted in; opium, of course, being at the same time employed in as large doses as are required to relieve the pain: after a few days, when the violence of the symptoms has abated and decided anæmia appears, the exhibition of the drug should be discontinued and potassium iodide, with tonics, be substituted. In cases subacute from the beginning I have found a combination of the potassium iodide and acetate very efficient, ten grains of the former and thirty of the latter being administered three or four times a day. The potash probably does good in rheumatism by lowering arterial action, by favoring oxidation and elimination of partially effete materials, and by neutralizing excessive acidity. Be the method what it may, I have no doubt of the great clinical value of the remedy, its efficiency being in direct proportion to the acuteness and violence of the symptoms.

As depurants, the potash salts are very useful in various diseases. Attention has been especially called by Dr. Golding Bird to their value in that class of cases spoken of as "*chronic biliousness*." In chronic malarial poisoning, in catarrhal jaundice, and in the jaundice of simple hepatic torpor, they are often of use. In uric acid gravel and in uric acid calculus there can be no doubt of the value of potash as a prophylactic, as a preventive of the formation or deposition of the uric acid. The

remedy has also been used to dissolve uric acid *calculi*; but the results offer such slight encouragement that it is only necessary here to give a reference to the work of Dr. Wm. Roberts (*On Urinary and Renal Diseases*, Am. ed., 1866).

ADMINISTRATION.—As usually exhibited, the potash salts are exceedingly distasteful. There is no need of this whatever. The citrate may be given dissolved in lemon-juice, or, what is a still more pleasant method, a syrupy solution of the bicarbonate and the citrate may be made, of such a strength that every tablespoonful of it shall contain half a drachm of each salt. At the time of exhibition one or two tablespoonfuls of this may be put in a little water, and to it be added a large tablespoonful of lemon-juice, the whole to be drunk while effervescing. If the patient takes in the course of the day six of the largest doses mentioned, the whole amounts to an ounce and a half of potassium citrate. When the remedy is used simply as a depurant, as in jaundice, such large doses are, of course, not proper; a teaspoonful of the alkaline solution, with a corresponding amount of lemon-juice, taken three times a day, will generally be sufficient.

POTASSII BITARTRAS, U.S.—*Potassium Bitartrate*, made from argol (see **TARTARIC ACID**), occurs in white crystalline crusts or masses, which are commonly pulverized before being sold as *Cream of Tartar*. It usually contains calcium tartrate, and is only sparingly soluble in cold water. It appears to differ therapeutically from its congeners in being more actively diuretic, and in acting more powerfully as a hydragogue cathartic. Half an ounce to an ounce of it given at once will very generally cause watery purging. In this city it is probably employed more frequently in *dropsy* than any other diuretic: the usual plan is to dissolve an ounce of it in a pint of infusion of juniper-berries, and have this all taken, in divided doses, during the twenty-four hours. In acute *desquamative nephritis*, cream of tartar is a very useful diuretic: as, however, the avoidance of irritation of the kidneys is imperative in this disease, the alkaline diuretic should not be administered in infusion of juniper.

Potassium Tartrate (**POTASSII TARTRAS, U.S.**) is rarely used in medicine. It is said to be actively purgative in doses of half an ounce.

POTASSII SULPHAS, U.S.—*Potassium Sulphate* occurs in small aggregated, transparent, very hard crystals, permanent in the air, usually short six-sided prisms, possessing a nauseous somewhat bitter taste. It is insoluble in alcohol, slowly soluble in nine and a half times its weight of cold and in less than four times its weight of boiling water. Potassium sulphate is said to be, in doses of four or five drachms, "a mild purgative, operating usually without heat or pain or other symptoms of irritation;" and in doses of one or two drachms a laxative. It is, however, very rarely employed in this country. Potassium sulphate,

in doses not a great deal in excess of those which have been recommended by practitioners, acts as an irritant. Dr. Mowbray states that the salt is used in France as a popular abortifacient, and that he has seen very alarming symptoms produced by four drachms of it. Dr. Taylor records a case in which less than two ounces caused in a woman severe vomiting, purging, abdominal pain, and finally death. At the post mortem the stomach and intestines showed very decided evidences of inflammation.

POTASSII NITRAS—POTASSIUM NITRATE. U.S.

Potassium Nitrate, or *Nitre*, is either obtained from certain saline earths, occurring chiefly in India, but to a certain extent in other portions of the world, or is artificially manufactured in nitre-beds formed out of animal and vegetable matter, wood-ashes, and calcareous earth, or is obtained from old plaster rubbish. In the "nitre-beds," as well as in the natural saline earths, which have undoubtedly in the beginning contained animal and vegetable matters in a state of decomposition, nitric acid is formed by the oxidation of ammonia, and unites with the bases in the soil. Most of the nitre used in this country comes from Calcutta, through Boston, packed in grass-cloth bags. *Chili saltpetre* is the *sodium nitrate*, which impregnates certain soils in the country whose name it bears. It is undoubtedly formed in these soils by a process precisely analogous to that in which the nitre of India is produced, except that, little or no inland vegetable matter being present to afford the potassium during the decomposition of the animal matter and the generation of nitric acid, the latter unites with sodium derived from sea-plants or other source. Chili saltpetre is employed as a substitute for true saltpetre in the manufacture of nitric acid, and may be made into potassium nitrate by means of crude potash.

Saltpetre occurs in more or less perfect, long, striated, semi-transparent, six-sided prisms, with dihedral summits; of a sharp, saline, somewhat cooling taste; containing no water of crystallization, but decrepitating when thrown on the fire, from the evaporation of water mechanically retained in the crevices of the crystals; soluble in four or five times their weight of cold and in two-fifths of their weight of boiling water, sparingly soluble in proof spirit, insoluble in absolute alcohol. At a high heat they decompose, liberating a large quantity of nascent oxygen, and thereby greatly intensifying the combustion of surrounding objects. The *Sal prunelle* of the shops is a saltpetre which has been fused and run into circular moulds.

PHYSIOLOGICAL ACTION.—Potassium nitrate applied to any raw surface, or to a mucous membrane, acts as a violent irritant. As death has not infrequently resulted from its ingestion, while it has occurred very rarely from that of any of the other ordinary salts of the alkali, it has generally been thought that nitre possesses peculiar properties. It is not to be gainsaid, however, that the cause of death in nitre-

poisoning is very generally the local inflammation of the stomach and intestines produced by it,—effects dependent simply upon its irritant properties, and not upon any constitutional action; a conclusion becoming doubly evident when it is remembered that if the drug be given in weak solution much larger amounts can be exhibited with only therapeutic effects than would cause death if administered in solid form or in very concentrated solution. Thus, in a case under the care of Dr. Wilks (*Guy's Hosp. Rep.*, vol. ii. p. 173, 3d series, 1863), a man suffering from renal dropsy took, between October 28 and December 26, 1862, one pound twelve ounces and six drachms of potassium nitrate, with benefit. As one ounce has caused death in three hours (Taylor, *Medical Jurisprudence*, 2d ed., vol. i. p. 237), this patient received in fifty-nine days the equivalent of twenty-eight fatal doses. Again, according to Professor Stillé (*Therapeutics*, vol. ii.), Dr. Brocklesby habitually prescribed one ounce of the salt a day, and Dr. Martin-Solon even two ounces per diem.

The symptoms of poisoning by potassium nitrate are pretty constant, and yet, as in other irritant poisoning, vary within certain limits. Very generally there is first an intense burning pain in the stomach, coming on in a few minutes after the ingestion of the poison, and soon followed by violent vomiting, and, it may be, free purging. In a little while collapse develops, with great muscular weakness, not rarely with local convulsive tremblings. The matters vomited, and even the stools, may be bloody (case, Th. Husemann, *Journal für Pharmacodynamik*, 1859, ii. 178). Sometimes the nervous symptoms predominate, and the purging may be absent; collapse, with slight vomiting and with or without paralysis of the lower limbs, may alone exist. Suppression of urine has been noted in some cases (case, *Pharmaceut. Journ.*, Feb. 1846, p. 356). After death, very grave lesions are found in the stomach and the intestines, such as intense redness and congestion, and effusion of blood into the submucous coat, and sometimes into the stomach itself. Even ulceration and corrosion of the mucous membrane have been observed. It is evident that the symptoms previously detailed as existing during life are in accord with the post-mortem results, and all point to the irritant action of the drug as the source of trouble. The predominance of the nervous symptoms in some cases is no more than is exceptionally seen in other forms of irritant poisoning (see ANTIMONY), and is no proof of a special action of the drug upon the nervous system. Sometimes, however, death has occurred, in poisoning by saltpetre, with great suddenness. In the only cases of this character the record of which I have met with, the dose has been very large, and it is possible that the death was the result of the action of the drug upon the heart, for, like the other salts of potash, it has a direct paralyzing influence upon the cardiac muscle.

Nitre has been supposed by practitioners to be especially sedative to the circulation; but there is no reason to believe that it is any more

powerful as a cardiac sedative than the vegetable salts of the base. It certainly shares the diuretic properties of the latter, but appears to be more irritant to the kidneys, since it seems difficult otherwise to account for the suppression of urine already noted as occurring occasionally in poisoning by it.

THERAPEUTICS.—Potassium nitrate has been especially used in *acute rheumatism*, and when given in large doses has some favorable influence upon the course of the affection. It is certainly, however, more dangerous than are the vegetable salts of the base, and, according to my experience, much less efficacious. I can therefore see no good reason for continuing the practice. If given, not less than an ounce should be dissolved in a full quart of barley-water or other demulcent, and be administered in divided doses during the twenty-four hours.

In the treatment of poisoning by saltpetre, after the stomach and bowels have been emptied, the usual means for the relief of toxic gastro-enteritis should be resorted to.

POTASSII CHLORAS—POTASSIUM CHLORATE. U.S.

This salt is said to be chiefly prepared by heating the solutions of the calcium hypochlorite and potassium chloride; on cooling, the potassium chlorate crystallizes out, whilst the calcium chloride remains in solution. Potassium chlorate occurs in white rhomboidal plates of a pearly lustre and of an acerb taste, soluble in seventeen parts of water at 59° F., and in two parts of boiling water.

PHYSIOLOGICAL ACTION.—Upon mucous membranes and ulcerated surfaces this salt acts as a powerful irritant, being, I think, even more active in this respect than is the potassium nitrate. Taken internally in sufficient quantities it is a powerful poison, and has frequently caused death. There are on record a large number of fatal cases, many of which are collected in the brochure of Dr. J. von Mering (*Chlorsäure Kali*, Berlin, 1885). To Dr. Jacobi, of New York, belongs the credit of having first called attention to the dangerous action of this much-used remedy (*American Med. Times*, April, 1861, p. 245). The smallest amount which will produce death is not known, but in a case recorded by Dr. Matthiesson a little over half an ounce taken in the course of several days proved fatal. Dr. Stockvis has seen the death of a man after four drachms. A drachm in the course of a night has killed an infant a year old, and three drachms a child three to four years old. In most cases of fatal poisoning in the adult the dose has been much over half an ounce. The symptoms may be acute or subacute. In the rapid cases there have been violent vomiting, profuse diarrhoea, excessive dyspnoea, great failure of the heart's action, and marked cyanosis. In most of these cases the blood has been found of a chocolate color. In the subacute cases the gastro-intestinal symptoms have been severe, with generally vomiting of blackish-green matters and distinct swelling of the liver and the spleen. The urine is markedly

lessened in quantity, albuminous, often of an opaque reddish-brown or blackish color, showing under the microscope brownish or yellowish-brown tube-casts, frequently containing the detritus of blood-corpuscles. Hæmoglobinuria has been noticed (*Trans. Internat. Congress*, 1881, vol. I. p. 463), and methæmoglobin is a common constituent. The nervous symptoms have been severe delirium, coma, tonic and clonic cramps, and a peculiar stiffness of the extremities.

Headache, loss of appetite, violent pains in the abdomen and other portions of the body, and marked abdominal tenderness have usually preceded the loss of consciousness. Not rarely there are minute ecchymoses upon the surface of the body, and even more frequently there is a general jaundice. In some cases the patient has rallied and seemed to be on the road to recovery when the fatal relapse has occurred.

After death the blood is usually chocolate-colored, the gastro-intestinal tract is inflamed, the liver and spleen are enlarged and filled with the brownish debris of red blood-corpuscles, the bone-marrow and the brain are often similarly colored, while the mucous membranes are usually swollen and ecchymosed. The kidneys are profoundly affected, their tubules full of brownish casts and their epithelial structure evincing a nephritis. The most characteristic and probably the most important of the lesions is the change in the blood, which was first noticed after death by F. Marchand (*Virchow's Archiv*, Bd. lxxvii., 1879). Dr. L. Riess (*Berlin. Klin. Wochenschrift*, 1882) noted in a case during life that many of the red blood-corpuscles were decolorized, and others contained little granules of an elliptic shape. The researches of Marchand's most recent paper (*Arch. f. Exper. Path. u. Pharm.*, xxiii.), which have been abundantly confirmed, show that the changes in the blood are the result of the formation of a substance apparently identical with the methæmoglobin of Hoppe-Seyler and characterized by the appearance in its spectrum of a blackish line in the red. Methæmoglobin is readily produced by mixing either sodium chlorate or potassium chlorate with blood: that it is produced in the body during life has been experimentally proven in cats, dogs, and rabbits by A. Falck (*Arch. f. d. Ges. Physiol.*, 1889), by H. Lenhartz (*Beiträge Path. Anat.*, etc., *Fest. Schrift*, 1887) and by Cahn (*Arch. f. Exper. Path. u. Pharm.*, xxiv., 1887), and is also shown in man by the widespread staining not only of the interior of the blood-vessels, but also of the walls of the whole lymphatic system, found after death from the chlorate. (Case, Dr. N. Hammer, *Prag. Med. Wochenschr.*, xiii., 1888.)

It was asserted years ago by Dr. Stevens that when potassium chlorate is taken internally the venous blood acquires an arterial hue, and the confirmatory statements of Dr. O'Shaughnessy led many of the profession to give credence to the idea that the chlorate yields its oxygen to the blood: so that it has been used to an enormous extent in various low forms of disease with the idea of increasing oxidation in the blood. It is most probable that the observers just quoted mistook

the altered coloration of the blood for the arterial hue. It is very improbable from a chemical stand-point that potassium chlorate should part with its oxygen in the blood at the temperature of the body, and there is no proof that it does so. It has been shown by Rabuteau and other observers that potassium chlorate escapes unchanged with the saliva, urine, and probably all the secretions of the body. Isambert found it in the tears, the bile, the nasal mucus, and even in the milk of nursing women. Rabuteau took five grammes of the salt, and recovered from the urine 4.873 grammes. Isambert, in two experiments, recovered respectively ninety-five and ninety-nine per cent, of the ingested potassium chlorate from the urine. J. von Mering, out of fifteen grammes given to a dog, obtained 14.7 grammes; out of five grammes which he took himself, he recovered 4.62 grammes; and when he took but a single gramme he obtained from the urine of the next ten hours 0.91 gramme. From the saliva and urine of a case of mercurial stomatitis in which five grammes had been exhibited he recovered 4.54 grammes. Indeed, Marchand claims, in experiments upon the lower animals, to have recovered all of the ingested chlorate from the secretions, and we must conclude that it practically all escapes from the body unchanged. F. von Mering believes that some of the potassium chlorate is reduced in the system, chiefly because he thinks that methæmoglobin is formed by a process of oxygenation. The exact nature of methæmoglobin is, however, not made out: according to C. A. Macmunn (*Spectroscope in Medicine*, p. 100, 1881), methæmoglobin is probably a mixture of hæmatin with soluble albumen, as it has been shown by Hoppe-Seyler that it is not formed by oxidation. M. von Mering in one or two instances in the dog found a slight increase in the chlorides of the urine during the administration of the chlorate, and it is possible that a minute quantity of the chlorate does undergo deoxidation, but it must be considered established that any such change, if it occur at all, affects so small a portion of the drug as not to be worthy of consideration.

The effect of therapeutic doses of potassium chlorate upon the system is certainly not marked, and is probably the same as that of the nitrate. The potash seems to exert some influence, as Isambert states that the drug directly injected into the jugular vein paralyzes the heart, and produces a general depression similar to that caused by the nitrate. In his experiments upon himself, Isambert found that when taken in large doses, two to five drachms a day, the chlorate caused salivation, free diuresis, increase of the appetite, and, when not well diluted, gastric irritation; the urine continued strongly acid, and contained an excess of rosæic acid, uric acid, and the urates.

THERAPEUTICS.—Potassium chlorate has been very freely used, and with great asserted advantage, in all forms of disease believed to be due to blood-poisoning, such as scarlet and other *adynamic fevers*, *diphtheria*, *scorbutus*, *syphilis*, and even *hydrophobia*. As already stated, the

theory upon which this practice rests has no foundation in reason or science, and my own empirical experience with the remedy has been in exact accord with the teachings of physiology. I have seen the chlorate repeatedly employed in various diseases of the class just spoken of, and have never seen it do a particle of good. On the other hand, in mercurial and other forms of *stomatitis* the remedy is undoubtedly of great value; given in the form of a powder, with sugar, it is remarkably efficient in the *follicular* or *aphthous stomatitis* of children.* I do not believe, however, that its influence in these cases is other than local; yet, as the remedy is eliminated with the saliva, and, therefore, when given internally is constantly present in the mouth, the ordinary method of using it is probably the best. In *ascites* and other *dropsical* affections it is valueless.

When used *locally*, potassium chlorate acts as a stimulant to the various mucous membranes, and is often of excellent service in cases of *angina*: it is even said to have been used advantageously by enema in *dysentery* and in *cholera infantum*. The most generally efficient gargle that I know of in ordinary *sore throat* may be made by pouring a pint of boiling water over a powder composed of an ounce of *sumach berries* (or of their fluid extract) and half an ounce of the chlorate of potassium, allowing to simmer in an earthen vessel, with occasional stirring, to three-fourths of a pint, straining, and using in the ordinary manner. A half-ounce to an ounce of the saturated solution of the chlorate combined with a few drops of laudanum, injected into the rectum once or twice a day and retained, is often of the utmost service in *hemorrhoids*.

ADMINISTRATION.—For manifest reasons, when taken in large doses potassium chlorate must be exhibited in dilute solution. The usual dose is from ten to twenty grains; as a lotion, from ten grains to half a drachm may be dissolved in the ounce of water.

LITHII CARBONAS, U.S.—*Lithium Carbonate* is a white powder, sparingly soluble in water, and readily distinguishable by the carmine-red color which it imparts to the flame of alcohol.

LITHII CITRAS, U.S.—*Lithium Citrate* is a white, deliquescent powder, soluble in two parts of water.

LITHII CITRAS EFFERVESCENS, U.S.—*Effervescent Lithium Citrate* is a white powder, each one hundred grains of which contains seven grains of lithium carbonate, twenty-eight grains of sodium bicarbonate, and thirty-seven grains of citric acid. When added to water it effervesces freely and affords the most pleasant means at our command of exhibiting an alkaline salt of lithium.

* M. Laborde (*Bull. Thérap.*, lxxxvii., 1874) and M. Taake (*Inaug. Diss.*, Bonn, 1878) have shown that sodium chlorate acts physiologically like the potassium salt; and Dr. S. Ringer and H. Sainsbury (*London Lancet*, 1882, ii. 736) have found it equally efficient in *stomatitis*.

THERAPEUTICS.—Therapeutic doses of lithium carbonate ordinarily produce no distinct symptoms, but I have seen repeated doses, of twenty grains each, cause in a feeble woman excessive malaise, with a muscular weakness amounting almost to paralysis, but to other patients I have given larger amounts without eliciting response. Our knowledge of its physiological action is not complete. According to the studies of Binet (*Revue Med. d. l. Suisse Romande*, viii., 1892), the lithium salts produce in mammals pronounced feebleness, with nausea, diarrhoea, and other digestive disturbance, increasing dyspnoea, fall of temperature, and death, usually preceded by convulsions. Death is said to be due to a direct centric arrest of respiration, although a markedly depressing influence is exerted upon the heart, which is finally arrested in diastole. When life is maintained by artificial respiration the peripheral nerves become entirely paralyzed and the muscles affected, as is shown by peculiar fibrillary contractions. In poisoned frogs, also, the excitability of the muscles is somewhat diminished. The effect of lithium salts upon tissue change has not been worked out, but it is probable that they act upon the general nutrition in a manner parallel to the influence of the potassium compounds. The soluble salts of the lithium are rapidly absorbed and rapidly eliminated through the kidneys: the carbonate and the citrate render the urine alkaline.

According to the experiments of Dr. Ure and of Dr. Garrod, solutions of the lithium salts have the power of dissolving uric acid and the urates; and the drug was strongly recommended by Dr. Garrod in *uric-acid diathesis* and in *chronic gout*, given in doses of three or four grains three times a day. The drug was extensively employed, but fell into disrepute until recently, when its claims have been revived, especially by Professor Dittierich (*Schmidt's Jahrbücher*, Bd. cli. p. 270). In my own experience, its continuous use in doses of from five to ten grains after meals has appeared to do great good in chronic gout. Dr. Martineau, of Paris, affirms that he has obtained very remarkable results in the treatment of *diabetes mellitus* by the use of a solution of lithium carbonate and sodium arsenate. In gouty diabetes this *arsenical solution of lithium* may probably be of service: from five to ten grains of lithium carbonate and one-thirtieth of a grain of sodium arsenate may be given three times a day. Dr. E. Duché (*Bull. de la Soc. Méd. de l'Yonne*, 25-27, 1884-86) affirms that the prolonged local application of lithium salts is of very great use in the treatment of *gouty joints*, and that in *gouty conjunctivitis* frequent washing of the eyes with the solution of lithium carbonate, one part to five hundred, is effective.

PIPERAZINE.—Piperazidine, or Diethylendiamine, occurs in small, glassy, lustrous tables, or, in the form of the *hydrochlorate*, in silky, lustrous, lanceolate crystals. Its value in practical medicine rests entirely on its solvent power over uric acid. In a cold watery solution it is said to dissolve twelve times as much uric acid as will lithium car-

bonate; and one part of uric acid and piperazine dissolves in fifty parts of water, whilst lithium urate requires 368 times its own weight to dissolve it. It is further claimed for it that it will dissolve not only uric acid, but the albuminous substances which form an important part of calculi. Dr. William A. Meisels (*Ungar Archiv f. Medizin*, Bd. i, 1893) has found that the uric-acid diathesis produced in birds by the use of the neutral potassium chromate is overcome by the exhibition of piperazine, but is not prevented by the lithium carbonate or the sodium borate or phosphate. Its physiological action has not been thoroughly investigated, but in the doses in which it has been given to human beings it usually does not cause any distinct symptoms; nevertheless I have seen muscular weakness and general depression follow its continuous exhibition. Van der Klip has found that in the lower animals, in sufficient dose, it produces vomiting, irregular breathing, general muscular weakness, and relaxation; that it also decreases the coagulability of the blood, and has power in checking the action of peptonizing ferments. He further states that it decreases the evolution of oxygen by oxyhæmoglobin.

According to Umpfenbach (*Nederl. Tydscher. voor Geneesk.*, 1892), piperazine is a powerful diuretic which may be useful in dropsies. Dr. Vogt (*Soc. Therap.*, 1891) affirms, as the result of his investigations, that in doses of fifteen grains (0.972 Gm.) a day it checks uric-acid elimination. On the other hand, Ebstein and Sprague found that the drug did not effect excretion of urea or of uric acid. It does not exert any distinct irritating influence upon the gastric or the genito-urinary mucous membranes. It has been largely used in the treatment of uric-acid gravel and calculi (especially renal), and also as a remedy in gout. My own experience is that in some cases of gout it seems to exert a beneficial influence, whilst in other cases it fails entirely, the cause of this difference not being discoverable. It is very rapidly absorbed and probably as rapidly eliminated through the kidneys, producing a reddish-brown urine from which it can be readily obtained. (See *New Remedies*, 1892.) Dr. H. Hildebrandt (*Berlin. Klin. Wochen.*, 1894) having found that piperazine, even in small quantities, checks the saccharifying influence of hæmic and other hydrolytic ferments, although it has no destroying influence, tried the drug in diabetes produced in dogs by phloridzin with pronounced success; so that the remedy is certainly worthy of trial in *diabetes mellitus*.

Piperazine may be given in the hypodermic injection of a two-per-cent. solution, which is said to produce some pain but no abscesses; or, better, fifteen grains (0.972 Gm.) of it may be administered during the day in a quart of plain or carbonated water. It is so highly hygroscopic that it cannot well be given in pill, but it may be ordered in powder if the druggist be directed to put up each day's allowance in a minute vial tightly corked. The injection of small doses of piperazine immediately into gouty joints is worthy of trial. The solution of

one part of pure piperazine in twenty parts of alcohol and eighty parts of water is said to be fairly permanent.

STRONTIUM.

PHYSIOLOGICAL ACTION.—Although various chemists, from Thomson, in 1818, to L. Gautier, in 1886, have affirmed that strontium and its salts are not poisonous, and although in a thesis inspired by M. Vulpian, in 1885, M. Ismael Hassan (*Thèse de Paris*, 1885) reported a case of *chronic rheumatism* in which fourteen grammes of strontium had been given a day, yet the general belief of the profession in its toxicity led to the total neglect of the remedy until attention was drawn by M. J.-V. Laborde, in 1891, to the value of the strontium salts in practical medicine. The general belief was dependent upon the fact that barium is so closely united with strontium in nature that only by great care is it possible to obtain chemically pure salts, whilst the presence of even a minute portion of barium makes the preparation violently poisonous. Laborde found that large amounts of strontium salts are borne by the lower animals without the production of any symptoms, so that two grammes of strontium carbonate given to the dog, by the stomach, daily for six weeks, had no effect save to improve the general nutrition.

The effect of strontium is often subordinate to that of the substances with which it is combined. Thus, in the experiments of Laborde a certain dose of strontium bromide caused localized anæsthesia with a rapid development of somnolence deepening into stupor, with marked lessening of reflexes; followed, if the dose had been large enough, by collapse, coma, and complete loss of reflex activity; whilst a similar dose of strontium chloride produced no sensible effect.

I am not aware of any case in which strontium salts have been taken by man in sufficient dose to produce distinct symptoms, but toxic doses cause in the lower animals (Binet, *Revue Med. d. l. Suisse Romande*, viii., 1892) general feebleness with increasing dyspnoea, cyanosis, clonic convulsions, and death from asphyxia. When recovery occurs the motor power gradually returns, with stiffness, ataxic movements, and not rarely with the assumption of bizarre positions. Our knowledge of the physiological action of the strontium salts is very imperfect. They probably have some influence upon tissue change similar to that possessed by potassium, but at present this is a mere supposition. According to Binet, they kill by centric arrest of respiration, the peripheral nerves preserving their excitability at the time of death. The same authority states that in the frog there is centric motor paralysis; the peripheral nerves and the muscles themselves being, however, finally depressed. The influence of the salts upon the circulation appears to be peculiar, but has not yet been properly worked out. Lanique and A. Malbec (*Compt.-Rend. d. l. Soc. Biol.*, iv., 1892) assert that strontium iodide produces a primary pronounced elevation of the arterial pressure, with a lessening of the beat of the heart; and

after a time, if the dose have been large enough, a marked fall of pressure accompanied by a very feeble rapid action of the heart; whilst Binet states that in poisoning by the strontium salts, although the cardiac beat is very feeble, the arrest finally takes place in systole.

The absorption of the strontium salts and their elimination, chiefly through the kidneys, appears to be rapid; according to Laborde, both the lactate and the tartrate are distinctly diuretic and markedly antiseptic, so that they exert a pronounced influence in the alimentary canal, and also on the excretions with which they escape from the body.

The U.S. Pharmacopœia recognizes three preparations of strontium.* Of these the iodide has already been noticed (see page 811).

STRONTII LACTAS, U.S.—*Strontium lactate* occurs as a white granular powder, or in crystalline nodules. It is odorless, of a slightly bitter saline taste, permanent in the air, and soluble in about four parts of water; also soluble in alcohol. According to Professor Germain Séé, Paul, Dujardin-Beaumetz, and other French clinicians, it is a valuable remedy in the treatment of chronic *Bright's disease*, increasing the amount of urine, diminishing or arresting the excretion of albumen, and improving the general nutrition. In albuminuria due to pulmonary congestion the drug is said to be of no service, and it is further affirmed that its influence for good is especially marked in *desquamative nephritis*, and much less pronounced in *interstitial nephritis*. In many cases there is no increase in the flow of urine, and the good achieved seems to be due to an alterative influence upon the secreting structure of the kidney. The drug exerts the general favorable influence of the strontium salts upon the alimentary canal, and has been used with alleged excellent results in the treatment of *rheumatism* and *gout*, in which diseases it is claimed that it increases the nitrogenous elimination and causes the disappearance of the urates. The usual dose is from twenty to thirty grains, given three times a day in solution; but much larger amounts have been exhibited without producing apparent symptoms.

STRONTII BROMIDUM, U.S.—*Strontium bromide* occurs in colorless, odorless, very deliquescent crystals of a bitter saline taste, soluble in 0.5 per cent. of water and readily soluble in alcohol. It has been used in doses of from forty to eighty grains a day in the treatment of *epilepsy*. I have myself employed it quite largely. It differs from the other bromides in not disturbing digestion; indeed, it usually improves the appetite and increases the activity of the digestive organs. It is

* The presence of strontium phosphate in bone-ash is affirmed by some and denied by other chemists. According to the experiments of Max Cremer, the feeding of strontium phosphate to young hounds has no influence in preventing the development of rickets (*München. Med. Wochens.*, 1892).

much less prone to produce acne and other disagreeable symptoms of bromism, but has seemed in my experience to have less control over the epileptic paroxysms than have the older bromides. I have come to use it chiefly as an adjuvant to the latter, especially of the ammonium bromide.

ALTERATIVE DIURETICS.

BUCHU—BUCHU. U.S.

The leaves of *Barosma betulina* and *crenata*, natives of Southern Africa. These leaves, which are gathered by the Hottentots, are an inch or less in length, from three to five lines broad, of various forms, but always notched on the edges, and having a strong, rather rank, yet somewhat aromatic odor, and a warm, bitterish taste. They owe their virtues, which they yield to water and to alcohol, to a volatile oil and to a bitter extractive.

THERAPEUTICS.—Owing to its bitter principle, buchu is perhaps slightly tonic; but its chief medicinal virtue is as a stimulant and alterative to the mucous membrane of the genito-urinary organs. It does not very largely increase the flow of urine, and hence is never administered in dropsy, but in all cases of subacute or chronic inflammation of the genito-urinary organs it may be employed with hope of success. Its oil is undoubtedly absorbed, and is eliminated by the kidneys, to whose secretion it imparts its odor. In *chronic pyelitis*, *chronic cystitis*, and *irritation of the bladder*, it is one of our best remedies, especially when, as is frequently the case, these diseases are associated with a generally-lowered systemic tone. As compared with turpentine, buchu is much less stimulating, and has a much more soothing effect upon the mucous membranes of the genito-urinary tract. In *irritated bladder*, when the urine is highly acid, and when there is a constant desire to urinate, with but little relief from micturition, buchu, in combination with a vegetable salt of potash and the sweet spirit of nitre, often gives great relief. The dose of the *fluid extract* (*Extractum Buchu Fluidum*, U.S.) is a teaspoonful, well diluted, three or four times a day.

PARREIRA, U.S.—*Pareira Brava* is the root of *Chondodendron tomentosum*, a climbing plant of South America. There appear to be in the root one or more alkaloids (see *U.S. Dispensatory*, 15th ed., p. 1085). *Pareira Brava* has been used with asserted advantage in *chronic cystitis*, in "*irritable bladder*," and in *chronic gonorrhœa*, and appears to exert a stimulant action upon the mucous membrane of the whole genito-urinary apparatus. It is said to be also tonic, and slightly aperient, so that it is especially valuable in urinary diseases when there is feebleness of digestion and a tendency to costiveness. The remedy should always be given in the form of the *infusion* (Si-Oj), or of the *fluid extract* (*Extractum Pareiræ Fluidum*, U.S.), of which the doses are respectively a wineglassful and a teaspoonful three or four times a day.

UVA URSI, U.S.—*Bearberry* is the leaves of *Arctostaphylos Uva-ursi*, a low evergreen shrub, indigenous to northern maritime Europe, and also to our northern coasts as far south as New Jersey. They are from half an inch to an inch in length, wedge-shaped, thick, coriaceous, with a smooth, rounded margin. The odor is hay-like, the taste bitterish, astringent, and somewhat sweetish. *Uva ursi* contains gallic acid, besides a crystalline principle discovered by Mr. J. C. C. Hughes (*Amer. Journ. Phar.*, 1847), and by him named *Ursin*, but now generally known as *Arbutin*. It occurs in long acicular colorless crystals, freely soluble in water, less so in alcohol and in ether, and is resolved by the action of sulphuric acid into glucose and *hydrochinone*.

THERAPEUTICS.—*Uva ursi* is capable of acting as a weak astringent, but has been long used in medicine for its influence upon the genito-urinary mucous membrane, and at present is employed only in chronic *pyelitis*, *cystitis*, and other affections of the genito-urinary mucous membrane, when a slightly stimulant and an astringent action is desired. Mr. Hughes found that in doses of one grain *arbutin* is a powerful diuretic. It seems to be free from poisonous properties, as Jablonowski (*Inaug. Diss.*, Dorpat, 1858) took in forty-eight hours eighteen grammes of it without discomfort. It produces a discoloration of the urine varying from pale greenish to dark greenish brown, the color deepening upon standing. It has been proved by the researches of Von Mering (*Pflüger's Archiv*, 1877, xiv. 276), of L. Lewin (*Virchow's Archiv*, 1883, Bd. xcii.), and of Steffen (*Untersuchungen*, Würzburg, 1883) that the discoloration of the urine is due to the breaking up of the *arbutin* in the body into glucose and *hydrochinone*. The change probably occurs in the kidneys, as *arbutin* is free from toxic properties, while Brieger has shown that *hydrochinone* is poisonous, producing in man giddiness, ringing in the ears, lessening in the force and frequency of the pulse, etc. The experiments of Lewin indicate that the *arbutin* is the active principle of *uva ursi*, and Forster (*Aerztl. Intelligenzblatt*, 1881) has shown that *hydrochinone** is a powerful disinfectant and anti-

* According to the experiments of Brieger, *hydrochinone* produces in man giddiness, ringing in the ears, and lessening in the force and frequency of the pulse. In the experiments of Dr. P. J. Martin (*Therap. Gaz.*, 1887, 289) it caused in the frog violent convulsions, followed by paralysis and death through failure of the respiration, both convulsions and paralysis being the result of a direct influence upon the spinal cord. Small doses produced in the mammal increase of the arterial pressure, which, if the dose were sufficient, was followed by a depression. When the vaso-motor system was paralyzed and the heart isolated from the central nervous system, the effect of *hydrochinone* on arterial pressure was scarcely perceptible: so that it is probable that it chiefly affects the vaso-motor system. The bodily temperature is lowered by large doses of *hydrochinone*. According to the experiments of Martin, this is mainly due to an increase of heat-dissipation, and is, therefore, probably the result of a vaso-motor paralysis. H. G. Beyer, in experiments upon the frog and terrapin (*Amer. Journ. Med. Sci.*, April, 1886), comes to the conclusion that *hydrochinone* affects both the heart and the vessels as a paralyzant, lessening the rate of the heart and the amount of work done, and causing dilatation of the arterioles. Dr. Antaeff has found that if two per cent. of *hydrochinone* be added to fresh urine the latter will remain for many days without undergoing alkaline fermentation, but that if

ferment. It is stated that a one-per-cent. solution will arrest putrefaction and alcoholic fermentation, while one-half per cent. is sufficient to check butyric fermentation. On the other hand, H. Paschke (*Wien. Med. Presse*, 1884, xxv. 13; confirmed by H. Laurentz, *Inaug. Diss.*, Dorpat, 1886) states as the result of the practical use of arbutin in gonorrhœa and cystitis that it does not effect much good, and that only a portion of it is changed into hydrochinone, most of it being eliminated as arbutin. He believes that uva ursi is of value in genito-urinary diseases, chiefly on account of its tannic acid and of the volatile oil which it contains, and affirms that the dried extract of the leaf, the best preparation, contains about three and one-half per cent. of arbutin to sixteen per cent. of tannic acid. In the hands, however, of Dr. Menche (*Centrbl. f. Klin. Med.*, 1883, p. 433), arbutin in doses of twelve grains a day has proved a very decided diuretic and very useful in cystitis. Whatever may be the value of arbutin, it is evident that the solid extract (*Extractum Uvæ Ursi*, U.S.) fully represents the drug, of which it is about four times the strength. It may be given in drachm doses three or four times a day. The dose of the fluid extract (*Extractum Uvæ Ursi Fluidum*, U.S.) is two to four fluidrachms three to four times a day.

CHIMAPHILA, U.S.—*Pipsissewa* is the dried leaves of *Chimaphila umbellata*, a little indigenous perennial, distinguished from its inert congener *C. maculata* by the uniform glossy green of its leaves. The latter are about an inch and a half long, wedge-shaped, notched, pointed, and coriaceous. They contain tannic acid, bitter extractive, and, according to Mr. Samuel Fairbank, a crystalline principle, *Chimaphilin* (see *U.S. Dispensatory*). *Pipsissewa* is probably about equivalent to uva ursi in its therapeutic value, though perhaps not quite so actively diuretic. Professor George B. Wood (*Therapeutics*, vol. i. p. 133) commends it very highly in external *scrofula*, asserting that he has had a large experience with the remedy, and that in power over the disease it stands next to cod-liver oil and the preparations of iodine and iron. He believes that it acts not only as a mild astringent and tonic but also as an alterative, and states that its exhibition should be long continued, the administration being temporarily suspended whenever there is much fever. The remedy should be administered in the form of decoction, or of the fluid extract (*Extractum Chimaphilæ Fluidum*, U.S.), the doses of which are respectively a wineglassful and a teaspoonful three or four times a day.

JUNIPERUS.—*Juniper* is the fruit of the common juniper, *Juniperus communis*, of Europe and this country. These berries are round, bluish

hydrochinone be added to a solution of urea a rapid decomposition of the urea occurs, which Antaeff believes to be the result of a direct chemical action of hydrochinone on urea (*Lancet*, April, 1887).

bodies, about the size of a large pea, of a sweetish, terebinthinate, aromatic taste. They owe their properties to a *volatile oil* (*Oleum Juniperi*), which is official. They yield to boiling water and to alcohol. Juniper is gently stimulant and cordial to the stomach. Upon the kidneys it exerts a decided stimulant action, and the oil freely given is capable of irritating the renal organs above the secreting-point, and of producing lessened secretion, strangury, and even suppression of urine. The volatile oil is absorbed, and escapes from the system chiefly through the kidneys. As a diuretic, juniper has two distinct uses. The most usual employment of it is as an adjuvant to cream of tartar or the alkaline diuretics. On account of its stimulant local influence upon the alimentary canal, it renders the cream of tartar far more acceptable to the stomach, and at the same time aids its diuretic action. Sometimes juniper is employed for its stimulant action on the mucous membrane of the genito-urinary organs in *chronic pyelitis* and in *chronic catarrh of the bladder*. In the form of the *compound spirit* (*Spiritus Juniperi Compositus*, U.S.), or its equivalent, *gin*, juniper is often useful in the *subacute congestion of the kidneys* frequently seen in old persons and characterized by aching in the loins and lessened urinary secretion without more serious symptoms. Dose, two to four fluidrachms. The *infusion* is made by macerating an ounce of the berries in a pint of boiling water for an hour, the whole to be taken in divided doses during twenty-four hours. The dose of the oil (*Oleum Juniperi*, U.S.) is from five to fifteen drops; of the *spirit* (*Spiritus Juniperi*, U.S.), from thirty to sixty minims.

OLEUM ERIGERONTIS, U.S.—*Erigeron Canadense*, or *Canada Fleabane*, contains a large proportion of a yellowish volatile oil of a rather pleasant odor and taste, which has properties resembling those of turpentine, but much less stimulating. It may be employed in affections of the *genito-urinary organs*, and in *passive hemorrhages*. It is especially valuable in *menorrhagia*. According to Dr. Starke, it is very efficacious in *gonorrhæa* (*Lond. Med. Rec.*, 1876, p. 267). The dose is five to twenty drops every two or three hours, and is best administered on sugar.

OLEUM SANTALI, U.S., is a pale-yellowish, strongly aromatic volatile oil, of a pungent, spicy taste, from the distillation of the wood of *Santalum album*. It is insoluble in water, but readily soluble in alcohol. When pure, it is a local irritant and probably capable of affecting the general system, although its physiological action has not been properly investigated. Dr. S. Rosenberg (*Therap. Monatshefte*, 1887, p. 219) has noticed after doses of sixty drops a day irritation of the alimentary canal, burning in the urethra during urination, and an eruption of small red prominences upon the entire surface of the body, involving even the conjunctiva. Oil of sandal-wood is very efficient in *chronic bronchitis* and in the advanced stages of *acute bronchitis*, also in

gonorrhœa after the first period of acute inflammation. From ten to twenty minims of it may be given, in capsule or emulsion, three or four times a day.

ZEÄ, U.S.—The styles and stigmas (the "silk") of *Zea Mays*, or Indian corn, has been strongly recommended as a mild stimulant diuretic in acute and chronic inflammations of the bladder, and in uric-acid and phosphatic gravel. It is claimed that it has a distinct anæsthetic effect in allaying the pain of these affections, unless there be so much mucus as to prevent its contact with the mucous membranes. M. Landrieux, of Paris, asserts that the urinary secretion is much increased, and the arterial tension distinctly augmented, even in cases of cardiac disease (*Med. and Surg. Reporter*, 1882, p. 103). Dr. Vauthier (*Arch. Méd. Belges*, Aug. 1880*) states that its activity depends upon *Maizenic acid*. It may be given *ad libitum* in infusion (two ounces to the pint of boiling water); the dose of the fluid extract (*Extractum Zeæ Fluidum*, U.S.) is one to two teaspoonfuls every two to three hours; of the maizenic acid, one-eighth of a grain. Dr. Ducasse gives half a drachm of the extract a day (*La France Méd.*, 1882, p. 811). Dr. E. Stuver (*Ther. Gaz.*, vol. ii.) claims that the fluid extract (3i every two hours, with acetate of potassium gr. x) exerts an extraordinary influence over acute *gonorrhœa*.

TEREBINTHINA—TURPENTINE. U.S.

Canada Turpentine (TEREBINTHINA CANADENSIS, U.S.), or *Canada Balsam*, is the product of *Abies balsamea*, or Balm of Gilead, or American Silver Fir, as it is variously named, a beautiful evergreen indigenous to the extreme northern United States and to the British provinces. The juice is said to collect in little receptacles under the bark, and to be gathered by cutting these open and allowing them to drain into vessels. Canada Balsam is a thick and viscid but clear, yellowish liquid, containing, it is said, about twenty per cent. of volatile oil. The amount of the latter ingredient must vary greatly, since by age and exposure to the air the liquid balsam, losing its oil by evaporation and oxidation, becomes converted into a hard, brittle, translucent, resinous mass. Canada Balsam is very rarely, if ever, used in medicine, but resembles turpentine in its action on the system.

White Turpentine (TEREBINTHINA—TURPENTINE. U.S.) is the concrete oleoresin obtained by incising *Pinus palustris* and other species of pine. The supply in the American market comes almost exclusively from North Carolina and other of our Southern States. It is rarely, if ever, itself used in medicine, but by distillation is separated into a volatile oil and a resin (*Rosin*), which is official under the name of *Resina*. *Emplastrum Resinæ*, U.S., *Adhesive Plaster*, or, in ordinary

* Consult also *La France Méd.*, 1880, xxvii. 99; *L'Union Méd.*, April, 1880; *Med. News*, xliii. 372.

language, "*Sticking Plaster*," is formed by adding rosin to lead plaster. *Ceratum Resinæ*, U.S., *Resin Cerate*, or *Basilicon* ointment, contains rosin, yellow wax, and lard; it is used as a mildly stimulating application to indolent burns, ulcers, etc.

OLEUM TEREBINTHINÆ. OIL OF TURPENTINE. U.S.

This is a yellowish, highly-inflammable oil, of a strong peculiar odor and a hot biting taste, moderately soluble in alcohol, freely so in ether, very slightly so in water. By heating with muriatic acid it is converted into a red liquid and a white crystalline substance, which, from its resemblance to camphor, has received the name of *artificial camphor*. Turpentine is remarkable for having the property of absorbing oxygen and converting it into ozone.*

PHYSIOLOGICAL ACTION.—Turpentine is a powerful irritant, causing in a very short time inflammation in any tissue with which it comes in contact.

When taken by a healthy person in moderate doses, it produces a sense of warmth in the stomach, soon followed by exhilaration, and, if the amount be sufficient, giddiness and even a species of intoxication. The pulse is increased in force and frequency. The turpentine escapes from the body through the lungs and kidneys, imparting its own odor to the breath, and that of violets to the urine. Although several recorded instances prove that turpentine is capable of producing death, cases of serious poisoning by it are rare, and a lethal result is exceedingly so. The symptoms noted in poisoning by it are most of them constant, but vomiting and purging are present in some cases and not in others. Unconsciousness is generally complete, and occasionally is accompanied by dilated pupils; the urine is very much lessened in quantity, often bloody, not rarely suppressed; the skin is sometimes dry, sometimes moist; the pulse is feeble, rapid, and generally regular.

The lethal dose must be very large, but it is not definitely known, since recovery from four ounces in an infant fourteen months old has been reported. In Dr. Maund's case (*Annuaire de Thérapeutique*, 1846), death was supposed to have been produced in an intemperate woman by six ounces; and Philip Miall has recorded an instance of death produced in an infant fourteen weeks old by turpentine, of which half an ounce was thought to have been taken (*London Lancet*, March, 1869).

Our knowledge of the action of turpentine upon the circulation is very imperfect: the results which have been obtained by experimenters are so diverse as to indicate that different varieties of the oil affect the circulation differently, or else the oil alters in its physiological influ-

* Certain preparations of turpentine containing ozone or antiozone have been recommended in medicine. Some experiments which I myself made by injecting ozonized water into the blood of lower animals showed that when given in such way the ozone acts chiefly as a blood coagulant. (For a study of the effect of the ozonizing turpentine oils, see Falloa, *Dorpat Thesis*, 1859.)

ence when allowed to stand and absorb ozone. Dr. R. Kobert, using the European turpentine (*Centralbl. für Med. Wissensch.*, 1877, p. 129), found that in moderate doses it exerted a powerful stimulating influence upon the inhibitory reflex centre, and also elevated the blood-pressure by stimulating the vaso-motor centre. Very large doses appeared to paralyze both of the centres spoken of, causing decided fall in the arterial pressure. The respiration was first increased in frequency, but later strongly diminished. The blood became very dark, and the heart was finally paralyzed. The vagi and depressor nerves did not appear to be affected, nor indeed did any of the peripheral nerves, or the muscles. It is said that these results are in accord with those previously published by Azary in the Hungarian language, and Dr. Hoppe (*Journ. für Pharmacodynamik*, i. 105) concludes as the result of his own experiments, presumably made with European oil of turpentine, that the vaso-motor nerves are very early influenced by the drug. On the other hand, in a series of experiments made in the Laboratory of the University of Pennsylvania by Dr. H. A. Hare (*Med. News*, Nov. 19, 1887) with American oil of turpentine, it was found impossible to raise the arterial pressure for more than two or three minutes, and then no more than ten millimetres of mercury. Large doses produced a pronounced fall of arterial pressure, with great cardiac depression, to which, indeed, Dr. Hare attributes the fall of the blood-pressure. Doses which had no effect on the blood-pressure increased the frequency of the pulse for a length of time. The increase of the pulse-rate was evidently due to an action upon the heart itself, for it occurred when the turpentine was applied directly to the heart of the frog as well as in the dog after section of the accelerator nerves and the vagi. When large doses were administered the pulse became slow,—probably, as Dr. Hare believes, as the result of stimulation of the pneumogastric nerves, since section of these nerves was followed by the normal rise in pulse-frequency. F. Fleischmann (*Schmidt's Jahrb.*, clxxx. 125) found that two drops produced paralysis in the frog—first of voluntary and afterwards of reflex activity; in the cat and in the rabbit, toxic doses abolished reflex activity, but caused violent lethal convulsions. The preservation of voluntary movement after the loss of reflex activity in the frog, which has been confirmed by Dr. Hare, indicates that toxic doses of turpentine paralyze the sensory nervous system, either in the cord or in the peripheral nerves.

The irritant action of turpentine upon the kidneys and genito-urinary tract is very decided. When moderate doses (ten drops every three hours) of turpentine are taken, there are usually no renal symptoms produced, except a slight increase of the urine. Somewhat larger amounts, when exhibited, are apt to give rise to aching in the loins and to frequent micturition, with perhaps urethral pain accompanying the act. If still larger quantities are ingested, these symptoms are intensified, and at the same time the secretion of urine is diminished. After

very large repeated doses of the drug, the aching in the loins is very great, often with spasmodic pain in the ureters; a constant desire to pass water struggles with the inability to micturate, caused by the urethral spasm; the urine is very scanty, albuminous, and even bloody; priapism may be present, and an intolerable irritation may affect all the pelvic organs. Léon Crucis (*De Li Terebinthine*, Paris Thesis, 1874) has made some experiments which indicate that when turpentine is given in toxic doses to rabbits it increases the coagulability of the blood and gives rise to numerous minute hepatic and pulmonic thrombi.

THERAPEUTICS.—Externally the oil of turpentine is very much employed as a powerful counter-irritant. It is useful more especially when it is desired to act upon a large extent of surface. When a very intense permanent local impression is required, a blister is to be preferred. Thus, in *pleurisy* a blister may be used, in *bronchitis*, turpentine stupes. In preparing the latter the turpentine should first be warmed by setting the vessel containing it in hot water, then a piece of flannel, just previously saturated with hot water and wrung out as dry as possible, should be dipped in the turpentine and again wrung out. It is then ready for application, and may be left on from fifteen minutes to half an hour, according to the sensitiveness of the skin.

Another local use of the oil of turpentine is as an addition to enemata. From a teaspoonful to an ounce of it mixed with double its amount of olive oil renders opening enemata much more active, especially in causing the expulsion of flatus. Turpentine enemata containing much of the oil in a small bulk are also constantly used with good effect in arousing the system from stupor arising from narcotic poison or similar causes.

In *ulceration of the bowels*, turpentine taken by the stomach is often very efficient, probably acting locally in the intestine, and in old gastric ulcers good results are sometimes derived from its use. In a single large dose (℥ss to ℥i, with an equal amount of castor oil) it is an efficient vermifuge. It may also be used as a stimulant in *low fevers*, particularly when the tongue is dry and red.

In *typhoid* or *enteric fever* it without doubt acts as a local stimulant to the ulcerated bowel, besides influencing the general condition of the system. There are two conditions or stages in the diseases named in which it is especially useful,—indeed, is of incalculable service. About the end of the second week the tongue sometimes becomes very dry, red, chapped, perhaps coated in the centre with a brownish fur, and at the same time marked meteorism develops. Ten drops of turpentine every two hours during the day and every three hours during the night will in the majority of cases remove the bad symptoms noted. That the action of the oil is largely a local one is shown not only by the arguments of the introducer of the practice, Dr. George B. Wood, but also by the value of the same treatment when diarrhœa persists after the acute stage of the fever has passed. When convalescence is pro-

tracted, when there is a constant tendency to the recurrence of diarrhæa,—when, in other words, the ulcers of Peyer's patches are slow to heal,—turpentine acts almost as a specific. These clinical results have received scientific confirmation in the work of Theo. Omelchenko (*Bull. Gén. Thérap.*, 1891), who finds that the bacillus of typhoid fever will not develop in air containing diluted vapor of turpentine, and dies when the atmosphere is saturated with the vapor. Thymol appeared to be even more active than turpentine.

In *typhoid bronchitis* and *pneumonia*, especially as intercurrent in typhus fever and similar diseases, turpentine applied externally and taken internally is often very useful. The same may be said of the low forms of *puerperal fever*. In this disease the abdomen should be kept covered with fomentations of the oil and of warm water alternately, the counter-irritant being used as constantly as a proper regard for the skin of the patient will allow. Internally it should be given in very large doses (℞x to ℞xv every two hours).

In *hemorrhages* from the stomach, bowels, or lungs, turpentine has acquired celebrity, but it is hardly so much used as formerly. It is in the ataxic cases that it is useful. I have very rarely employed it, as the oil of *erigeron* has seemed even more efficacious, and is much more pleasant to the patient. In *purpura hæmorrhagica* turpentine has been highly praised.

Oil of turpentine is never employed to increase the flow of urine for the purpose of affecting serous effusions. As a diuretic, it is used solely for its local influence upon the organs. *Excessive diuresis* sometimes is apparently dependent upon a relaxed condition of the kidneys, and under these circumstances oil of turpentine may be of service. *Chronic pyelitis*, *chronic cystitis*, and *gleet* may be very much benefited by the use of the drug.

In using turpentine in these cases, it should always be borne in mind that, with the exception of cantharides, it is the most actively stimulating of all the diuretics, and must be employed only when such a remedy is called for. In those comparatively rare cases of *urinary incontinence* which are dependent upon debility of the bladder, turpentine is sometimes of great service. When the same symptom is spasmodic, the remedy, of course, is harmful. In absolutely passive *hematuria*, in *impotence*, in certain conditions of *spermatorrhæa*, in *amenorrhæa*, when great local debility exists, turpentine may be tried with fair hopes of its being useful. The dose of turpentine is ten to fifteen drops in emulsion, given from four to six times a day. If glycerin and oil of *gaultheria* be added to the emulsion in such proportion that half a teaspoonful of the one and one or two drops of the other are taken with each dose, they will almost completely disguise the taste of the remedy. The drop of turpentine is about equal to half a minim.

It has been asserted that oil of turpentine is a powerful bactericide; but the experiments of Koch and of Christmas-Dirckinck-Holm-

seld (*Fortschritte der Med.* Oct. 1, 1887) appear to show that its antiseptic properties are feeble.

CHIAN TURPENTINE, the product of *Pistacia Terebinthus*, has been highly commended by Mr. John Clay as a remedy for internal cancer. Considerable testimony has been given by other physicians as to its value, and I have myself seen it apparently do good. Nevertheless, it has not fulfilled its early promise, and it is at present employed only, if at all, with the hope of palliation. It is essential that it be genuine. Dose, six grains three times a day continuously.

COPAIBA—COPAIBA. U.S.

The oleoresin of *Copaiba langsdorffii* and of other species of *Copaiba*, large trees growing in Brazil. Copaiba is a yellowish liquid, of varying viscosity according to age, of a strong, terebinthinate, peculiar odor, and a bitter, burning, disagreeable taste. It mixes uniformly with absolute alcohol and volatile and fatty oils, and is readily dissolved by ether. It contains a volatile oil, a small quantity of soft, viscid resin, and about fifty per cent. of a hard, acid resin. In 1829, Schweitzer (*Poggend. Annal.*, Bd. xvii. pp. 487 and 1095) announced that he had found in copaiba a peculiar crystallizable acid, *Copaivic Acid*. It is not in the plan of the present work to discuss elaborately the chemistry of drugs, and consequently I must remain content with the statement that the researches of Professor Bernatzik (*Prager Vierteljahrschrift*, 1868, Bd. c., p. 239) have shown that very frequently this crystalline acid does not exist in copaiba, and hence that it is an unimportant constituent. Indeed, these researches seem to me to prove conclusively that copaiba is simply an oleoresin.

PHYSIOLOGICAL ACTION.—When given in therapeutic doses, copaiba has very little if any action upon the general system, and the influence even of very large amounts is often scarcely perceptible. In the researches of Bernatzik (*loc. cit.*, p. 251), eighteen grammes of the volatile oil were taken in three doses during twelve hours, and caused only an acceleration of a few beats per minute in the pulse-rate, and a rise of a fraction of a degree in the temperature, with, after a time, violent gastric and intestinal disturbance, evidently due to the local action of the drug, and characterized by vomiting and purging. Complete strangury was not produced, but there was some difficulty in passing the urine, which caused decided burning in the urethra. On the other hand, the action of the drug is much more decided upon some very susceptible persons, so that full doses of it produce decided fever, with increased frequency of pulse, and hot skin, accompanied almost always by decided symptoms of gastro-intestinal irritation. Sometimes, also, the urinary organs are more sensitive than usual to the action of the drug, so that strangury, and, as is stated by some authorities, even almost complete urinary suppression, may occur.

In 1841, Dr. G. O. Ray (quoted by Bernatzik) called attention to the fact that if nitric acid be added to the urine of persons taking copaiba, a precipitate is formed resembling that of albumen. This fact has been noted and commented on since its discovery by Dr. H. Weikart (*Archiv der Heilkunde*, 1860), by Dr. Rees (*Guy's Hosp. Rep.*, vol. xvii.), by Valentine (*Grundriss der Physiologie*), and by other observers. In order to produce the phenomenon with distinctness and certainty, it is seemingly necessary to use large doses of the drug, since Weikart failed to detect it after the exhibition of small amounts of copaiba oil. Various surmises as to the nature of this precipitate have been indulged in; but the experiments of Bernatzik (*loc. cit.*, p. 252) appear to show that it consists of the oxidized oil united to some urinary principles. Dr. Bernatzik found that the elimination of the oil goes on slowly, continuing for as much as four days after its ingestion when large doses are employed. In his experiments with the resin of copaiba, the authority just noted exhibited fifteen grammes of it inside of five hours. It acted as an emeto-cathartic, causing a great deal of pain and irritation. The urine deposited very copiously on the addition of nitric acid, the resin seemingly being eliminated more abundantly than was the oil. Copaiba does not increase to any great extent the amount of the renal secretion, and no evidence has, that I am aware of, been offered to show that it affects materially the solids of the urine. Professor Quinke has recently found (*Arch. f. Exper. Path. u. Pharm.*, 1883, xvii. 273) a new substance, *copaiba-red*, in the urine of persons taking the oil of copaiba. The substance is a colorless acid, forming easily soluble salts, and has the property of reducing the oxide of copper and polarizing to the left. It is colored red by sulphuric acid, gives a characteristic spectrum, and is soluble in water, chloroform, and amyl alcohol, but not in ether. Its presence can be detected by warming the urine with concentrated sulphuric acid, when a rose-red color is produced, deepening into purple-red. The color may usually be developed by allowing the urine to stand with about five per cent. of sulphuric acid; a precipitate forms after a time, at first colorless, but finally becoming of a dirty violet. After the use of copaiba resin the *copaiba-red* cannot be detected in the urine, but the urine still responds to Trommer's test for sugar. These facts are important as showing how a false diagnosis of diabetes might be made.

The clinical employment of copaiba has shown that the drug exerts its peculiar stimulant alterative action on other mucous membranes than those of the genito-urinary apparatus, and it is very possible that a slight elimination of the volatile oil takes place through the lungs.

THERAPEUTICS.—The chief use of copaiba in medicine is in *subacute and chronic inflammations of the genito-urinary mucous membrane*. In its action upon this structure it is a decided stimulant, but is less irritating and less stimulating than the oil of turpentine. *Gonorrhœa* is the disease in which it is mainly exhibited. It is especially useful in

the advanced stages of this affection. If it be given in the beginning, before the inflammation has fully developed, it may sometimes succeed in aborting the attack, but, if it fail to accomplish this, may greatly aggravate the symptoms. During the height of the inflammatory stage, copaiba should not be employed. In other inflammatory affections of the genito-urinary mucous membrane, such as *pyelitis*, and chronic *cystitis*, when the disease is of a subacute or chronic character, the remedy may be employed, it being borne in mind that in its action it is much more stimulant than huchu or *parcira brava*, but much less so than turpentine.

In chronic *diarrhœa* and *dysentery*, copaiba is sometimes of use, through its local action on the diseased surfaces. The remedy has been highly recommended in the advanced stages of *bronchitis*; and in the chronic form of the disorder, when attended by very free mucopurulent expectoration, I have occasionally employed it, with excellent results. Copaiba is sometimes used internally in *skin-affections*, but more frequently is employed externally as a stimulant dressing. The resinous mass which is left behind after the distillation of the oil of copaiba is stated to be an active hydragogue diuretic, increasing greatly the flow and lessening the specific gravity of the urine. In *dropsies* not dependent upon renal disease it is stated to be very efficacious given in doses of fifteen grains three times a day (*Guy's Hosp. Rep.*, 1876).

ADMINISTRATION.—The dose of copaiba is ten to twenty minima, repeated from three to six times a day, according to circumstances: the best effects are probably to be attained by the frequent use of small quantities. The medicine may be given dropped upon sugar, or, what is much better, exhibited in an aromatic emulsion, made with syrup and mucilage of gum-arabic in such a manner that a tablespoonful shall contain the required dose. When patients object to the taste, the drug may be given in gelatin capsules, each containing ten drops. It is said that these capsules do not, however, agree so well with delicate stomachs as the emulsion. When copaiba is rubbed up with magnesia, the resin unites with the earth to form a solid mass, in which the oil is mechanically held (*Massa Copaibæ*, U.S.). Pills made in this way are ineligible, being with difficulty disintegrated and absorbed. The oil (*Oleum Copaibæ*, U.S.), which is prepared by distillation, is isomeric with oil of turpentine. It may be exhibited in emulsion or in capsules in doses of eight to fifteen minima.

CUBEBA—CUBEB. U.S.

The unripe fruit of *Piper cubeba*, a climbing plant of Java and other portions of the East Indies. These berries are blackish-veined, about the size of a small pea, and have attached to them a short stalk three or four lines long. Their odor is aromatic and peculiar, their taste warm, camphoraceous, and peculiar. Cubebs is a somewhat complex body, but there can be no doubt that the ethereal extract, or

oleoresin, as it is commonly called, represents its medicinal virtues. The extract appears to consist chiefly of three substances,—a volatile oil and the brown resinous substance formed by its oxidation, a peculiar acid, and a neutral crystallizable principle, *Cubebin*. *Cubebic Acid* was first discovered by Mouhoim, but has been especially examined by Professor Bernatzik (*Prager Vierteljahrschrift*, 1864, Bd. lxxxi. p. 9). It is nearly tasteless, forms salts with the bases, has a very faintly acid reaction, and dissolves in concentrated sulphuric acid with the production of (according to Bernatzik) a purple-violet color, changing on the addition of a little water to a cherry-red, and altogether disappearing when further dilution is practised.

PHYSIOLOGICAL ACTION.—In some respects, cubeba, when taken internally, resembles black pepper in its effects. It is, however, much less stimulating than its congener. After the ingestion of the ordinary therapeutic dose of cubeba, nothing unusual is experienced; but when very large amounts are taken there are evidences of gastric excitement, such as sensation of warmth in the stomach, and slightly-increased frequency of pulse and heat of skin, with perhaps some giddiness or headache. The urine is slightly increased in amount, and acquires a peculiar odor. When very large doses are ingested, the symptoms of gastric irritation are more severe, and the subject suffers from gastric burning, nausea vomiting and colicky pains, with, in some cases, purging.

An eruption resembling urticaria has been occasionally noticed after the exhibition of cubeba: it is exactly similar to the eruption sometimes caused by copaiba, and, like it, is probably due simply to gastric irritation.

That the active principles of cubeba are eliminated by the urine is well established, as, after the exhibition of the drug, when nitric acid is added to the urine, a precipitate, resembling somewhat that of albumen, occurs.

The most elaborate physiological study of cubeba that I have met with was made by Professor Bernatzik (*loc. cit.*). This experimenter took himself, and gave to a student, ten grammes of the cubebate of magnesium. No decided symptoms were induced by this, further than some pulse-acceleration and gastric uneasiness; but the elimination of uric acid was greatly increased, and the cubebic acid was found in the urine. Half an ounce of the oil of cubeba was taken in thirty-six hours, the last three doses, aggregating ten grammes, being ingested in six hours. This was followed by very decided gastric irritation, and by the appearance in the urine of the oil, not as it was ingested, but oxidized and in the form of a resin; the eliminated uric acid was about one-third in amount of that excreted after the exhibition of cubebic acid. Of the powdered cubeba, fifty grammes were taken in eight hours; the gastro-intestinal irritation was very marked; the nitric-acid precipitate was abundant in the urine; the elimination of uric acid

was about midway between the extremes of the previous experiments. According to the researches of Professor Bernatzik, *cubebin* is inert.

THERAPEUTICS.—Cubebæ has been used to some extent for its local stimulant action upon the alimentary canal, but for this purpose is very inferior to black pepper and other spices. It is at present almost exclusively employed to influence the genito-urinary mucous membrane in precisely those cases in which copaiba is exhibited. The two drugs have very nearly the same range of action, but the cubebæ is less apt than is the copaiba to derange digestion. Very often the best effect in *gonorrhœa* and other genito-urinary disorders is obtained by giving the two remedies in combination. Cubebæ is sometimes employed with asserted advantage in chronic *hemorrhoids*, and also in those varieties of *bronchitis* in which copaiba is useful. It forms the basis of certain proprietary lozenges much used by public speakers and others to relieve the relaxation of the larynx which follows slight colds or over-use. For this purpose the berries themselves may be chewed, and are very effectual. In *coryza*, the powdered drug used as a snuff has sometimes a beneficial effect. It should not be employed in the early stages before secretion has been established, but is indicated later in the affection, when the discharge is profuse.

ADMINISTRATION.—The dose of powdered cubebæ is from half a drachm to three drachms, which may be exhibited in syrup or molasses three times a day. The volatile oil of cubebæ (*Oleum Cubebæ*) is official, and may be given in emulsion three or four times a day, in the dose of fifteen drops, gradually increased to half a drachm, unless some effect is previously produced upon the urinary organs. This oil does not so thoroughly represent the crude drug as does the official *oleoresin* (*Oleoresina Cubebæ*), which may be given in doses of from ten to fifteen minims, increased as necessary. It is best administered in emulsion, but may be exhibited in the form of a bolus, enough sugar having been added to make a plastic mass. The *tincture* (*Tinctura Cubebæ*—20 per cent., U.S.) is an ineligible preparation; dose, ℥i to ℥ii. The dose of the *fluid extract* (*Extractum Cubebæ Fluidum*, U.S.) is ten to forty minims.

Matico, U.S.—*Matico*, the dried tops of the *Piper angustifolium* of Peru, contains a volatile oil, resin, and, it is said, a bitter principle, *Maticin*. It is a softish mass which is largely employed as a styptic, and probably acts chiefly mechanically, coagulating the blood in its interstices, adhering to the wound, and thus arresting the hemorrhage. It has also been employed in internal *hemorrhages*, and in *gonorrhœa*. In these affections it probably acts similarly to oil of turpentine, although much less of a stimulant, and much more feeble. The *fluid extract* (*Extractum Matico Fluidum*, U.S.) and the *tincture* (*Tinctura Matico*—10 per cent., U.S.) may be respectively given in doses of forty-five minims and two fluidrachms.

KAWA.—The root of *Piper methysticum* is used in the Sandwich Islands as the basis of an intoxicating liquor known as kava-kava, kawa, or ava. It contains a crystalline principle analogous to piperin, which its discoverer, M. Gobley, called *methysticin*, besides an acrid resin, for which the name of *kawin* has been proposed, and a volatile oil. Dr. L. Lewin (*Piper Methysticum*, Berlin, 1886) finds that when the kawa resin is injected into the frog it produces a very pronounced loss of sensation at the point of injection, due to a paralysis of the peripheral endings of the sensory nerves, and that after the absorption of the remedy there is loss of voluntary motion and reflex activity, which is chiefly of spinal origin. In experiments made upon the warm-blooded animals he obtained similar phenomena,—namely, local anæsthesia at the point of injection, followed, after absorption, by general paralysis, due to a direct depression of the motor side of the spinal cord, the motor nerves and the muscles remaining intact. According to Dario Baldi (*Schmidt's Jahr.*, Bd. cccxxxix.), the active principle of kawa produces in the dog a very short period of excitement of the sensory nerves, followed by a complete paralysis, at a time when the whole motor system still responds to stimuli. According to his experiments and those of Randolph (*Med. News*, Feb. 13, 1886), brought in contact with a mucous membrane, the resin produces a burning pain, which is followed in a very short time by a complete and persistent loss of sensibility. Lewin (*Deutsche Zeitung*, Feb. 1886) found that six or seven minims of a solution of kawa injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass over for eight days. The great loss of muscular power which is said to follow kawa debauch in those unaccustomed to the use of the drug shows that its influence upon the spinal centres in man is the same as in other mammals.

In small doses kawa is said to act as a stimulant tonic, but when taken in large amounts to produce an intoxication which differs from that caused by alcohol in being silent, drowsy, and without emotional exaltation. A decoction of the root is used in Oceanica very largely in the treatment of *gonorrhæa*, and recently its value has been strongly affirmed by Dr. Sanné (*Journ. Thérap.*, 1886). It is not probable that kawa resin will prove a local anæsthetic of practical value, because it is insoluble in glycerin or in water, and at first produces in sensitive mucous membranes great pain. The dose of the root itself, given in *decoction*, is half a drachm three or four times a day; of a *fluid extract*, half a fluidrachm.

CANTHARIS.—*Cantharides* is considered elsewhere in detail (see **EPISPASTICS**), and it is only necessary here to say a few words in regard to its use in diseases of the genito-urinary tract. The active principle of Spanish flies is certainly eliminated by the kidneys, and acts therefore locally upon these organs, as well as upon those over

which their secretion flows. The influence exerted by this means is simply one of intense irritation, cantharides being an irritant to these organs in any dose sufficiently large to have an effect. Indeed, of all the officinal drugs cantharides is the most actively irritant to the kidneys and subordinate organs. Consequently it is employed only when an intensely stimulant action is desired, as in obstinate *gleet*, in which affection it is often combined very advantageously with the tincture of chloride of iron. In *pyelitis* and *cystitis* it is very rarely indicated, but may be cautiously employed in very chronic cases. The *tincture* of cantharides is the only preparation used internally. For the dose and method of administration, see EPISPASTICS.

FAMILY V.—DIAPHORETICS.

DIAPHORETICS are those medicines which are employed to increase the action of the skin. It is scarcely in place here to discuss the results of suppression of the functional activity of the skin or the importance of the surface-elimination to the system. It does seem well, however, to call attention to the fact that the perspiratory glands have a double function to perform,—that of elimination, already alluded to, and that of keeping down the temperature of the body during exposure to heat. When a man enters a Turkish bath the temperature of which is perhaps 160° F., or when he works in the sun on a very hot day, there is, if he be used to such exposure, little or no rise in the temperature of the body, because the surface-glands secrete sweat so actively as to expose a great amount for evaporation, and by the conversion of so much water into vapor such an amount of heat is absorbed—i.e., converted from heat into repulsive force—that the body is cooler. The reason that even a moderate degree of heat in a moist atmosphere is intolerable is because evaporation cannot take place.

From what has already been stated, it is obvious that the use of dry external heat, or rather exposure to a hot atmosphere, is a powerful means of producing perspiration: it is, indeed, in healthy men the most powerful method at our command. It may be applied either in the form of the *Turkish bath*, in which the air of the hot chamber is very dry, or in the *Russian* or *vapor bath*, in which the atmosphere is surcharged with hot vapor. Very wonderful therapeutic properties have been ascribed to the direct action of heat (Urquhart, *Manual of the Turkish Bath*, London, 1865)* when applied by the Turkish bath; but the remedy appears to me to act only as a powerful sudorific, perhaps also doing good in some cases of acute internal congestion by attracting the blood to the surface and thereby depleting the interior. In private practice, or whenever a properly-provided bath cannot be commanded, a very efficient and readily-applied substitute consists of a large tin funnel furnished with a long bent beak, a stool with a hole in the centre

* The term Turkish Bath is here applied to the bath used in this country under that name. This bath appears not to be a copy of the Oriental bath, but merely a derivative from it. According to a writer in the *British and Foreign Medico-Chirurgical Review* (vol. xxviii. p. 87), in the East the sudarium, or sweating-chamber, rarely has a temperature of more than 98° F. Consult also *Bathing; How to Do It, When to Do It, and Where to Do It*, by E. Sheppard, London, 1865; *The Anglo-Turkish Bath*, by Y. J. Moore, London, 1865.

of its seat, or else a few bricks, and a large spirit-lamp. The patient being closely wrapped up in bed, and the clothes being especially "tucked in" about the neck and shoulders, the funnel is placed upon the stool or the bricks in such a manner that the beak of it enters well under the bedclothes, coming close to but not in contact with the person of the sick man. The spirit-lamp, being then placed immediately under and close to the funnel, must, when lighted, send a column of hot air and vaporized water through the beak into the space around the body of the patient. When the lamp is sufficiently large, and a little care is taken to see that the nozzle of the funnel is not obstructed by the bedclothes, the process just detailed affords a very efficient method of giving a vapor-bath.

Hot-water baths offer another very successful method of inducing profuse perspiration. The patient should be placed in a bath of about 98° or 100° F., and remain there fifteen or twenty minutes, during which time, by the repeated addition of very hot water, the temperature should be raised to 110° F., or to such point as the patient can endure. Warmed blankets having been plentifully provided, the sick man should be lifted from the bath into them, be closely wrapped up, and so left for three or four hours before being transferred to the usual bed. According to Dr. A. Steffen (*Jahrb. für Kinderheilk.*, Hft. iii., 1871), after this use of the bath the body has been proved to undergo loss of weight continuously for one or two days.

Profuse sweating is always more or less exhausting, but is not nearly so much so as purging, and therefore may be practised in dropsical patients too feeble to allow of the use of purgatives. The hot baths are not, however, altogether free from danger or objection. Sometimes in the Turkish and Russian baths the patient fails to sweat freely, and a feeling of distress, a bounding, rapid pulse, and perhaps severe headache, develop themselves: under these circumstances the bodily temperature rises, and a fever develops, which may go on to the production of a true "thermic fever," and perhaps terminate in sudden death. This is an exceedingly rare result, and one that never can occur if the patient is removed from the hot chamber so soon as any unpleasant symptoms are manifested. Sudden death has, I believe, taken place once from "sun-stroke" in a patient while taking the "Turkish bath," also once from "congestion of the lungs" (*Brit. Med. Jour.*, Oct. 1878).

The use of hot baths of any kind is, of course, contra-indicated by the existence of fever; but, according to Dr. Steffen, the hot-water baths are pre-eminently contra-indicated by the existence of congestion or œdema of the lungs, or of a tendency towards these disorders, since under such circumstances the bath greatly increases the disease, or precipitates a perhaps fatal attack. My own limited experience, so far as it has gone, has corroborated these statements of Steffen. I have seen, under the conditions mentioned, the most frightful dyspnoea result from the use of the hot-water bath, a dyspnoea which was apparently

prevented from terminating fatally only by the removal of the patient from the bath-tub. If disturbance of the respiration comes on during the bath, the patient should be immediately taken out, and, if the symptoms be urgent, cold water should be freely dashed over the head, neck, and chest.

Diaphoretics produce the desired result in various methods, which may be briefly considered under four headings, representing as many modes of action.

First. *By relaxing the skin.* As has already been sufficiently shown (see CATHARTICS, p. 742), there is a form of secretion, or perhaps it would be more correct to term it of leakage, from mucous membranes, which is distinctly paralytic in its mechanism. The same assertion may be made in regard to the skin: the colliquative so-called "night-sweats" of phthisis afford a familiar example of this, occurring as they do in profoundly debilitated subjects, and at such times as there is the greatest relaxation of the system,—i.e., during sleep. The profuse sweats of collapse also may be instanced as examples of the general truth just enunciated. Normal processes which produce great relaxation cause great sweating: thus, during vomiting, especially if it be accompanied by much nausea, the skin pours out its secretion. By virtue of this general law certain remedies act as diaphoretics. All of the diaphoretics which cause sweating by producing relaxation, and which are employed in medicine, are nauseants, constituting a distinct group,—the *Nauseating Diaphoretics*.

Second. *By reducing the force of the circulation.* There is undoubtedly a condition of over-action or over-rapidity of the circulation in which the affected glands are unable to perform readily their normal functions. Thus, it is well known that the first stage of inflammation is one of arrested secretion, and that in high fever there is a general drying-up of the secretions. The skin does not differ from other organs in this respect: consequently its functional activity may fail because of excessive arterial action. Hence there is a class of remedies which, although perhaps not actively sudorific in health, are in disease very efficient in reducing the circulation and restoring the functional activity of the skin. It is evident that there is a close connection between the present mode of influence and that noted in the previous section; and it is no less apparent that the nauseant diaphoretics act most powerfully in reducing the circulation. There are, however, certain diaphoretics which act in the present method but are not nauseants: these sudorifics form a separate class by themselves,—the *Refrigerant Diaphoretics*.

Third. *By entering the circulation and directly stimulating the glands of the skin.* It appears to be a general law that when any medicinal principle is eliminated by any excretory organ, the general activity of that organ is increased by the effort at elimination. Thus, the vomiting and purging of arsenical or antimonial poisoning, the increased urinary secretion following the ingestion of a potassium salt, are ap-

parently the results of attempted elimination. The skin undoubtedly eliminates medicinal substances, and is undoubtedly subject to the general law: consequently there is a class of remedies which increase its action by a direct influence.

It is manifest that a drug may relax the general system, may diminish the force of the circulation, and also may stimulate directly the skin: indeed, it is most probable that antimony does all of these; and at least some of the refrigerant diaphoretics probably act in the last two ways. There are, however, certain substances which seem to cause sweating purely by stimulating the function of the skin. These are in this work grouped as *Simple Diaphoretics*.

Fourth. *By filling up the blood-vessels.* There is much reason for believing that precisely as under certain circumstances water, by increasing the amount of the blood, will provoke increased renal secretion, so, under other circumstances, it will cause increased dermal excretion. The antagonism which exists between the skin and the kidneys in regard to the amount of their respective secretions has already been sufficiently dwelt upon (see *Diuretics*). It seems well to reiterate, however, that warmth favors the action of the skin, while cold stimulates the renal activity. Thus, large draughts of water, if taken cold, the patient being kept cool, increase the urine, but, if they be taken hot, and the patient covered up warmly in bed, increase the perspiration.

Diaphoretics are employed in the practice of medicine to fulfil the following indications:

First. *To arrest forming diseases* of not very severe type, probably by causing a flow of blood to the surface, and thereby relieving slight internal congestions, and possibly by eliminating principles which have been retained in the blood instead of being excreted as they ought to have been. In *general cold*, in *muscular rheumatism*, *suppressed menstruation*, and other results of exposure to cold and of checked perspiration, the diaphoretics afford the most efficient means at our command for restoring the normal functions.

Second. *To favor absorption.* In *dropsy* the diaphoretics are of very great value, often aiding diuretics and purgatives in effecting a cure, and sometimes, when these fail, or when circumstances forbid their use, rescuing the patient from impending death. None of the medicinal diaphoretics except *jaborandi* are of sufficient power to be relied upon in dropsy. The Turkish, the Russian, and the hot-water bath are capable of producing sufficient sweating to cause absorption of dropsical fluid, but must be vigorously employed.

Third. *To aid in the subsidence of diseases* which naturally pass off with a sweat. The chief use of diaphoretics for this purpose is in *miasmatic fevers*, especially in the *remittent* form of the affection, when the sweating stage fails to develop itself thoroughly and the paroxysms run into one another. Even in the single paroxysm of *inter-*

mittent fever, by hastening the closing stage, diaphoretics will often shorten the paroxysm.

Fourth. *To eliminate noxious materials from the blood.* The old humoral idea of the ground-work of such diseases as fevers, the belief in a distinct *materies morbi* which could be eliminated from the blood, has no sufficient demonstration to be accepted, and, although diaphoretics do good in fevers, yet it cannot be granted that it is in this manner. The very great power of increased diaphoresis in cooling the body through surface-evaporation has already been dwelt upon; and much of the good effected by diaphoretics in diseases of high temperature probably has its origin in this power. Modern science seems, however, clearly to point out that this class of remedies may aid in separating from the blood retained secretions, and may to some extent replace the action of the kidneys when these organs are disabled by disease.

In 1851, Dr. Schottin (*Archiv für Physiolog. Heilkunde*, Jahrg. xi.) discovered urea in the sweat of patients suffering from the collapse of cholera. Not only has the discovery of Schottin been confirmed by the researches of G. O. Rees (*Encyclopædia of Anatomy*, vol. iv. p. 841), of Fiedler (*Diss. Inaug.*, Leipsic, 1854), of Hirschsprung (*Gaz. des Hôpit.*, 1865), of Kaup and Jürgensen (*Deutsches Archiv für Klin. Med.*, 1869, Bd. vi. p. 54), of Leube (*Ibid.*, 1869, Bd. vii. p. 3), and of G. Deininger (*Ibid.*, p. 587), but it has also been abundantly proved that the skin excretes urea freely during the advanced stages of Bright's disease, and also during the partial urinary suppression of scarlatinal desquamative nephritis. The urea in renal disease may even form a distinct crystalline powder on the skin; but it is most abundant about the mouths of the sweat-glands. I believe Landerer was the first to announce that urea was present in the sweat of healthy persons; and, although chemists of excellence have been unable to detect it, its presence at times can no longer be denied, since it has been found not only by Landerer, but also by Funke in 1858 (*Moleschott's Untersuchungen*, Bd. vi.), by Meissner (*De Sudoris Secretione*, *Diss. Inaug.*, Leipsic, 1859), and by Leube (*loc. cit.*); Fourcroy (quoted by Rees) has also found it in the sweat of horses. By a series of elaborate experiments, Leube (*loc. cit.*) has rendered it probable, if he has not actually proved, that in health there is such a relation between the skin and the kidneys that when the former is very active the latter excrete less than the normal amount of urea.

When to the facts already cited are added the observation of Griesinger, that in diabetes the perspiration contains sugar, and the well-known circumstances that in rheumatism the sweat contains lactic acid, and in jaundice biliary products, the value of diaphoretics as a means of getting rid of retained excretions becomes manifest. For this reason, in *Bright's disease*, especially of the acute form, they are of the greatest value, acting beneficially in three different ways,—by

drawing the blood to the surface, and thereby relieving any internal congestions of the kidneys or other organs that may exist; by promoting the absorption of dropsical effusions; and by eliminating retained secretions.

NAUSEATING DIAPHORETICS.

The most frequently employed medicine of this class is *tartar emetic*. This substance is so fully discussed in the earlier portion of this book that very little need be said about it here. It seems well to point out, however, that the antimonials act as diuretics, even when not given in doses sufficient to cause nausea, and that they do so apparently in two ways,—by reducing the force of the arterial circulation, and by a direct action. They are probably eliminated to a very slight extent by the skin; although this has not, to my knowledge, been proved. Tartar emetic is to be employed as a diaphoretic in sthenic cases only, and is especially used in *inflammatory fevers*. The dose of it as a diaphoretic is from the sixth to the twelfth of a grain. If a diaphoresis is urgently demanded, the dose should be gradually increased until decided nausea is induced. An excellent combination in many cases is tartar emetic, neutral mixture, and a minute amount of morphia.

Ipecacuanha is another nauseating substance which, like tartar emetic, seems to exert an influence upon the skin, even independently of its action on the stomach. Moreover, like the antimonials, it never in small doses by itself causes profuse sweating, but simply seems to aid in maintaining the insensible perspiration and in keeping the skin soft and pliable in inflammatory fevers. Partly for this reason it is frequently combined with mercury in such diseases as acute *peritonitis*. The diaphoretic dose of *ipecacuanha* is a grain every two hours. Some persons with delicate stomachs are decidedly nauseated by this amount; and to these only half a grain should be given at a time.

A very famous and efficient diaphoretic preparation of *ipecacuanha* is *Dover's Powder* (*PULVIS IPECACUANHÆ ET OPII*, U.S.), which contains one grain of opium, one grain of *ipecacuanha*, and eight grains of sugar of milk. Dover's powder is employed in two distinct methods. In some diseases, as in acute *rheumatism*, an opiate is indicated to allay pain or for some other purpose, and at the same time a diaphoretic is needed to keep up the action of the skin. Under these circumstances, from three to five grains of the compound powder of *ipecacuanha* may be given every two, three, or four hours, *pro re nata*. The medicine is more apt to nauseate when taken in powder than when exhibited in pills; for which reason the latter form of administration is preferable in the class of cases now under consideration, especially as the powder is to most persons a disagreeable medicine. In the second method of using Dover's powder, a single large dose is given for the purpose of producing profuse sweating. In the intense suffering which sometimes results from *suddenly suppressed menstruation*, the remedy is most effi-

cient, alleviating the pain and aiding in the production of the desired diaphoresis. In breaking up a cold, or in *muscular rheumatism*, Dover's powder is often used to cause sweating (see ALCOHOL as a Diaphoretic).

REFRIGERANT DIAPHORETICS.

Aconite, *veratrum viride*, and all the various remedies used to depress the cardiac action when excited, are, in the strictest sense of the term, refrigerant diaphoretics. Sufficient has, however, already been said in regard to their use. The *potassium citrate*, whether in the form of *effervescing draught* or of *neutral mixture*, is constantly employed in sthenic fevers, and affords, I think, the best basis there is for fever-mixtures in such cases, the more powerful depressants being added to it as circumstances demand.

SIMPLE DIAPHORETICS.

PILOCARPUS. U.S.—JABORANDI.

This drug, which has long been employed by the natives of South America, received its first notice, under the various names of *Jaborandi*, *Jaquarandy*, and *Jamquarandi*, from Dr. T. J. H. Lauggard in his "Diccionario de Medicina domestica," Rio Janeiro. 1865. It attracted no attention, however, until 1874, when it was brought to Paris by M. Coutinho. The leaves* alone are official; of them there are in commerce two varieties: the Rio Janeiro *Jaborandi*, which is believed to be the product of *Pilocarpus selleanus*, and the Pernambuco *Jaborandi*, the product of *P. jaborandi*. The two varieties agree in that the leaves are oval, oblong, and entire, one and two-tenths to one and five-tenths inches long, one-third to one-fourth as broad, with a bitter taste and a hay-like odor: they differ in that the Rio Janeiro leaves have a tendency to become obovate in shape and are not prominently veined upon the upper surface, whilst in the Pernambuco leaves the upper venation is very pronounced. Each variety contains the alkaloid pilocarpine, discovered by Byarson,† but the Pernambuco leaves are said to be much the richer.

* Under the name of *Jaborandi* various drugs other than the product of *Pilocarpus* are sold in Brazil. As the *Pilocarpus pinnatus* has been found to be active when grown in France, it is probable that the *Jaborandi* plant might be successfully cultivated in our Southern States. Dr. Froehde (*Berlin. Klin. Wochenschrift*, 1875) found the wood inert.

† A second alkaloid has been discovered by E. Harnack and H. Meyer and named *jaborine* (*Arch. f. Exper. Path. u. Pharm.*, xii.). It is a derivative of pilocarpine, and is said frequently to contaminate the commercial alkaloid. Its discoverers assert that they have studied its action upon the heart, pupil, intestines, and salivary glands, and found it identical with that of atropine. Its presence has no doubt been the cause of some contradictory results obtained by experimenters with pilocarpine. According to Professor Harnack, pilocarpine is readily converted into a second alkaloid, *pilocarpidine*, which produces, when in sufficient doses, excessive sweating, salivation, and also violent vomiting and purging, with colicky pain. In toxic amounts it causes great disturbance of the circulation and wide-spread muscular weakness. On the frog's heart, in small amounts it acts as an excitant, but in larger doses as a paralyzant. It is a very feeble local myotic. In its general influence it is very much less powerful than is pilocarpine (*Archiv f. Exper. Path.*, vol. xx.). Another derivative alkaloid is *jaborandine*, which Harnack has found to act on the frog's heart somewhat like atropine.

The U.S. Pharmacopœia recognizes the Pilocarpine (*Pilocarpinæ Hydrochloras*); whilst the Pilocarpine nitra (*Nitras*) is the official salt of the British Pharmacopœia. salts occurs in minute crystals or as a crystalline powder in water. In medical activity and dose they are equivalent to the other.

PHYSIOLOGICAL ACTION.—When an infusion of from grains of jaborandi is given to an adult, in about ten minutes the face and neck become deeply flushed, and free perspiration commences. After a hypodermic injection of the alkaloid, the effects may set in in six minutes. The sweating begins both on the face and the salivation are excessively profuse, and lasts for five hours. There is not rarely nausea, and sometimes vomiting. The pulse is usually more or less quickened, as is also respiration. After the sweating has ceased, the patient feels less exhausted. The nasal and lachrymal secretions are generally increased under the action of the drug, and M. G. has diarrhœa, which in the experiments of Ringer and others is present. There is sometimes contraction of the pupile and disturbance of vision. These effects of the drug are invariable; but subjects have been occasionally found susceptible to the action of the remedy, and, very rarely, in Ringer's experiments children were found to be very sensitive although doses of sixty grains were employed. Schwann (*Lyon Méd.*, Juillet, 1882), and other observers have found that very violent gastric and intestinal effects are produced by the drug.

Secretion.—The sweat produced by jaborandi is of variable quantity (nine to fifteen ounces by estimation). It is at first acid, then neutral, and finally clearly alkaline. Vuillemin (*Subst. toxiq.*, Paris, 1881, 87) denies that even the first is more than alkaline reaction, and believes, with MM. Luchsinger and others, that there has been a mistaken observation, due to the secretion of the sebiferous glands is acid. In the analysis of the chlorides were found in excess, the carbonates and urea in very minute amount, and the urea in more than five times the proportion, the amount eliminated in the sweating being from ten to fifteen grains. MM. Hardy and Ball believe from experiments the average amount of urea eliminated by the patient is seventeen grains (*Journ. de Thérap.*, 1874). Pilicier in a case with a gastric fistula great increase of the gastric juice was observed (1876, 430); the biliary secretion appeared to be increased on the other hand, M. Morat (*Lyon Méd.*, July, 1882) has observed an increase of the sugar in the blood, an evidence that the function of the liver is stimulated. Dr. Hamann found the secretion of milk lessened (*Arch. f. Gesam.*).

236). Whether or not the urine is increased in healthy persons when pilocarpine is given in a single large dose may be considered uncertain, but the assertion of M. Gubler that the alkaloid administered in very small repeated doses has a marked diuretic influence has received clinical confirmation. Much interest attaches to the effect of jaborandi upon urea-elimination, but it cannot be considered as determined, except that in various diseases the combined renal and dermal elimination is greatly increased by the drug. Hardy and Ball state that in health urea-elimination from the kidneys is diminished by the drug, while Professor Tyson and Dr. Bruon have found it increased both in health and in disease. The experiments have, however, been too few, and especially the conditions of their performance too lax, for much importance to be attached to them.*

There appears to be some relation between the flow of saliva and that of perspiration produced by jaborandi: if the one is very profuse the other is often, but not always, correspondingly scanty. Sometimes the salivation almost replaces the sweating (Féréol, *Journ. de Thérap.*, Jan. 1875); very frequently it commences before the sweating, and often it is more persistent. During it the mouth is warm, and there is often a feeling of tenseness about the maxillary glands. The saliva contains an abundance of salts and of ptyaline, as well as a small excess of urea (*Boston Med. and Surg. Journ.*, p. 347). Pilicier, it is true, states that the proportion of albuminous compounds, and especially of sulphocyanide of potassium, is much diminished, but in M. Robin's analyses the proportion was even beyond the normal, and Ch. Bongarel has by careful experimentation shown that the power of jaborandi-saliva in converting starch into sugar is equal to that of the normal secretion. According to I. N. Langley (*Brit. Med. Journ.*, p. 247), in the frog the mouth and skin, after the exhibition of jaborandi, become covered with a viscid secretion; in the dog, the rabbit, and the cat there is profuse salivation. The effect upon the salivary secretion must be due to a direct influence upon the gland, as it is produced equally well after section of all of the salivary nerves (Langley, *Journ. of Physiology*, 1878, 339; Carville, *Journ. de Thérap.*, 1875; confirmed by Schwann, *Med. Centralbl.*, 1875, p. 440); also when the drug is injected directly into the gland and prevented from entering the general circulation (Langley). According to the elaborate experiments of Langley, very small doses cause in the cat great increase of the secretion. Stimulation either of the chorda or of the sympathetic nerve causes respectively some increase or lessening of the secretion,

* As the result of experiments upon the lower animals, J. Horbaczewski (*Thérap. Gaz.*, 1893) believes that there is a distinct relation between the elimination of uric acid and the number of leucocytes in the blood, and that pilocarpine in proper dose increases the size of the spleen and increases also the number of leucocytes in the blood and the quantity of uric acid eliminated.

but this increase or lessening is not nearly equal to that which occurs in the normal animal, and is due to the action of the nerves upon the circulation, and not to any influence of their secretory fibres. Very large doses of the drug injected into the gland immediately arrest the secretion, and doses of less size given in the same way, while increasing secretion, paralyze both chorda tympani and sympathetic nerve, so that stimulation of them has no effect. It is probable from the last fact that jaborandi has an action upon the secretory gland-cells.

Although the evidence just deduced indicates that an influence is exerted by jaborandi upon the gland-cells, the fact that atropine arrests the jaborandi salivary secretion prevents us from considering it settled that the drug does so act upon the salivary gland cells rather than upon the peripheral nerve-endings, since there is reason for believing that the sweating which the drug causes is due to an action on the nerve-endings. Dr. Fuchsinger (confirmed by Nawrocki) has found that section of the nerves of the cat's leg did not prevent the paws from sweating when jaborandi was exhibited. This demonstrates that the action of the drug is peripheral, not centric. Five or six days after the section, when the peripheral nerve-endings had undergone degeneration, Fuchsinger found that jaborandi was unable to excite sweating. This, however, can hardly be considered to prove absolutely, as Fuchsinger claims, that the drug acts upon the peripheral nerve-endings and not directly upon the glandular cells themselves, since it is probable that these glandular cells shared the anatomical changes of the nerve-endings (*Pflüger's Archiv*, xv. 482).

The effect of pilocarpine upon secretion has suggested its use as a galactagogue, but in the series of elaborate experiments made upon cows, M. Ch. Cornevin (*Comptes-Rendus Soc. de Biolog.*, iii., 1891) found that pilocarpine had no influence upon the quantity of milk secreted, though it did appear to increase the production of the lactose.

Jaborandi appears to stimulate the nutrition of the hair, and Professor Prentiss, of Washington, has reported several cases in which the continued internal use of pilocarpine caused the hair to become exceedingly coarse and to change its color from light to dark (*Phila. Med. Times*, xi. 610). Dr. H. Rasori has noticed a tuberculated eruption apparently produced by jaborandi (*Trans. Internat. Med. Cong.*, 1881, iii. 146). M. Grocco has found that pilocarpine hypodermically injected or locally applied sensibly affects hysterical anaesthesia (*Lond. Med. Record*, 1882, 137).

Temperature.—The action on the bodily heat varies somewhat. M. Robin affirms that before and during the early stages of the sweating from jaborandi the temperature rises 1° to 2° F., but afterwards falls as much below the normal point and remains depressed for one or two days. This primary rise of temperature has been noted by other observers (Ringer, *Lancet*, 1873, i. 157; Greene, *Phila. Med. Times*, vi.

56; Scotti, *Berlin. Klin. Wochens.*, 1877, 141; Pilicior,* *Med. Centralbl.*, 1876, 429; Weber, *Ibid.*, 770), but is certainly frequently absent altogether or very trifling.† The subsequent fall of temperature seems to be a very constant phenomenon when the action of the drug is sufficiently severe; it probably depends in great part, or altogether, upon the loss of heat during the sweating.

Circulation.—The action of jaborandi upon the circulation has been studied by Mr. Langley (*Journ. of Anatomy*, x. 188), E. Leyden (*Berlin. Klin. Wochenschr.*, 1877, 406), Kabler and Sayka (*Med. Centralbl.*, 1876, 541), and Harnack and Meyer (*loc. cit.*, p. 374). The phenomena noted by these observers are in most respects in accord, but Kahler and Sayka using the extract of jaborandi, and E. Leyden commercial pilocarpine, have found the pulse either as a constant or occasional phenomenon at first increased in its rate, while Harnack has never seen this with chemically pure pilocarpine. It has been shown, however, by Professor E. T. Reichert (*University Med. Mag.*, 1893) that the result reached by Harnack was not due to the purity of the alkaloid, but to his not having used sufficiently minute doses. According to Reichert's experiments, the minute dose increases, the large dose decreases, the pulse-rate; there being a broad line between the two effects in which the pulse is normal. Immediately after the injection of the alkaloid into the jugular vein the arterial pressure falls, but in a few moments the characteristic phenomena of a slow pulse with increased arterial pressure come on. This slowing of the pulse is not prevented by previous section of the pneumogastric, but is at once set aside by an injection of atropine (Langley, Leyden, Harnack, and Meyer); as is also the diastolic arrest of heart which pilocarpine produces in the frog. Harnack and Meyer therefore believe that in both the frog and the mammal the chief cardiac influence of the alkaloid is exerted upon the intracardiac inhibitory ganglia; but Professor Ringer (*Practitioner*, xxvi. 12) finds that jaborandi and atropine act antagonistically upon the ventricles separated from the auricles, and, as the ventricles contain no inhibitory ganglia, some other explanation of the antagonism must be found.‡ The rise of the arterial pressure is stated by Harnack and Meyer to be prevented by the use of curare and artificial respiration, and to be, therefore, a secondary, not direct, result of the drug's action: it is probably due to the convulsive muscular contractions produced by the drug. In the latter stage of the poisoning the arterial pressure

* Pilicior noted that the rise occurred in the axilla, but not in the rectum: this would indicate that it is a local phenomenon, the result of a heating of the surface, not of the interior, of the body.

† Consult Riegel, *Berlin. Klin. Wochenschr.*, 1875 86; Bardenhever, *Ibid.*, 1877, 2 Auschmann, *Ibid.*, 353.

‡ Professor Ringer's explanation seems at present the most probable. It is, that pilocarpine paralyzes the heart by combining with the molecules of the excito-motor apparatus and of the muscular tissue, and that atropine displaces the pilocarpine and thereby substitutes its own action.

falls. As in the experiments of Harnack and Meyer asphyxia in this stage did not cause rise of pressure, although the heart appeared still to retain its force, the vaso-motor system is probably paralyzed, a conclusion confirmed by the later experiments of Reichert (*loc. cit.*). The pulse still continues slow, although, according to Harnack, the vagi are completely paralyzed.

Respiration.—According to the experiments of Morat and M. Doyon (*Compt. Rend. Soc. Biol.*, iv., 1892), pilocarpine produces a distinct slowness of the respiration, and as a respiratory poison is the antagonist to atropine.*

Sexual Organs.—Jaborandi does not appear to have any power over the sexual organs, except the pregnant womb. Cases of abortion during its use have been reported by M. Masmann (quoted by Larvand, *La Pilocarpine*, 1883) and by Schanta (*Wiener Med. Wochens.*, No. 18, 1878), but in the hands of other observers the drug has appeared to have little, if any, abortifacient influence, and M. Hyernaux and M. Chanteril have found it powerless in the lower animals (quoted by Larvand). When, however, the pregnant female is at her full term, the drug may affect the uterine contractions, as Larvand and others have noted an increase of the pains, or even a precipitation of labor, both in women and in the lower animals. Nevertheless, the oxytocic powers of jaborandi are very feeble. (See *British Medical Journal*, 1879, ii. 509; also *Wien. Med. Blatt*, 1879, ii. 1178, 1207.)

Motor System.—In man, muscular tremblings have been observed during the action of jaborandi, but it is doubtful whether they are due to a direct action of the remedy. In the frog, as first noticed by Murrell (*Pharm. Journ. and Trans.*, vi. 228), small doses (3 mgrm. of pilocarpine) produce violent convulsions with heightened reflex activity, while larger amounts cause complete palsy. According to Harnack and Meyer, the convulsions are due to spinal stimulation, and the paralysis partly to overwhelming of the spinal centres, and partly to paralysis of the muscles, the motor nerves themselves not being affected. The action of the drug upon the musculo-nervous system is entirely subservient to its other effects.

Eye.—When applied to the eye, pilocarpine produces great contraction of the pupil, tension of the accommodative apparatus, and an approximation of the nearest and farthest points of distinct vision (John Tweedy, *Lancet*, 1875, i. 159; C. Scotti, *Berl. Klin. Wochens.*, 1877, 143; Galezowski (*Med. Times and Gaz.*, 1877, ii. 358). Mr. Tweedy also states that there is impairment of vision, due to benumbing of the retina. According to P. Albertoni, the myosis is followed by a moderate but persistent mydriasis, and is not prevented by previous section of the oculo-motor nerve or of the upper cervical sympathetic ganglion.

* Dr. H. Druser (*Arch. f. Exper. Path. u. Pharm.*, xxx., 1892) has experimentally found that pilocarpine markedly increases the oxygen in the air of the swimming bladder of the carp.

It is certainly the result of a peripheral influence. Galezowski, who uses a solution of one part of a pilocarpine salt in fifty parts of water, affirms that it answers as well as a solution of eserine in diseases of the eye, and has the great advantage of not producing irritation.

THERAPEUTICS.—Jaborandi is so powerful and certain in its diaphoretic action that it has already taken rank as the most reliable and influential of the remedies of its class; indeed, so great is its power that it has widely extended the use of diaphoretics. It is doubtful how far it is applicable to the treatment of fevers, although the decided lowering of the temperature by it would indicate a power over such bodily conditions. In *bilious* and other *malarial fevers* it is probably of value, but sufficient use has not as yet been made of it to determine its exact powers in hastening the desired remission. In *typhoid* and other *asthenic fevers* it would probably do much injury. In *dropsies* it has been widely employed, and certainly is a most efficient remedy. It appears to be as safe in *asthenic dropsies* as in any other remedy comparable with it in power, although in my own observation a free jaborandi sweat is almost as exhausting as a purging. Great value has been ascribed to it in facilitating the removal of *local watery effusions*, such as occur in *pleurisy*, etc. Cases of *pulmonic œdema* have been reported in which lives seem to have been saved by its employment. In *uræmia* it is the most efficient remedy at our command. In *acute or chronic Bright's disease* it is of great value, sufficing often in the one case to bring about convalescence, and in the other greatly to prolong life and make it comfortable. The sweats may be repeated daily, bi-weekly, or weekly, according to the circumstances of the case. In *subacute and muscular rheumatism* jaborandi is very efficient. Dr. G. V. Hale (*Med. News*, 1892) commends highly the use of repeated small doses of pilocarpine in *erysipelas*.

The action of the remedy on the kidney is still *sub judice*. Purjesz (*Deutsch. Arch. f. Klin. Med.*, xvii. 533) has noted one case in which the drug seemed to produce albuminuria, but the occurrence may have been accidental, and there is clinical experience to show that when the pilocarpine is given in doses of one-tenth of a grain three times a day, so as to avoid any violent action upon the skin, there is a decided increase of the urine. In a case of my own, the urine, which had been absolutely suppressed for seventy-two hours, reappeared immediately after the hypodermic injection of one-twelfth of a grain of pilocarpine nitrate. The case of Purjesz and the occasional occurrence of strangury after the drug (my own experience, also Stumpf's, *Deutsch. Arch.*, xvi.) would indicate that it stimulates the urinary organs, and that some caution must be exercised in its employment in the earliest stages of *acute tubular nephritis*. Professor Ringer has reported several cases of *unilateral sweating* cured by the use of full doses of pilocarpine given hypodermically (*London Pract.*, xvii. 401), and it has been used with asserted success in *alopecia*. It has been extensively used in *diphtheria*

and croup, but has no direct influence over the disease, and may do great harm in adynamic conditions: by increasing the glandular secretion of the bronchial tubes it may aid in loosening the membranes.

M. Cheron has used the nitrate of pilocarpine hypodermically with very good success when the milk is becoming scanty in nursing women. The dose must not be large enough to produce diaphoresis,—not more than one-twelfth of a grain.

Locally applied (half-ounce of the leaves) in the form of a poultice, jaborandi may sometimes produce local sweating only, but I have seen very marked and extraordinarily prolonged general sweating so caused.

Pilocarpine is used by aurists both locally and hypodermically in the treatment of various diseases of the ear; Metcalfe (*Therap. Gaz.*, 1893) believes that the internal use of pilocarpine gives no good results, but that a solution of eight grains to the ounce is of value as a local application in *chronic tympanic catarrh*, and when applied to the external auditory meatus in dry conditions of the meatus and membrana often affords relief.

ADMINISTRATION.—The dose of jaborandi is forty grains to a fluid-drachm. The *fluid extract* (*Extractum Pilocarpi Fluidum*, U.S.) may be used in doses of half a drachm to a drachm. Pilocarpine is superior to jaborandi in the certainty of its action, and in being less disagreeable, and probably less apt to nauseate. Weber, Bardenhewer, and Auschmann agree that 0.3 of a grain of it is equal to seventy-five grains of the best leaves; but this is probably an overestimate of its powers. In the form of the *hydrochlorate* (*Pilocarpinæ Hydrochloras*, U.S.) it may be used hypodermically in watery solution, the dose being from one-eighth to one-third of a grain. Dr. Demme, of Berne, gives to children between one and two years old 0.075 grain; between two and six, 0.1 to 0.15 grain; between six and twelve, 0.15 to 0.35 grain, and finds it to work very well (*Med. Times and Gaz.*, 1877, ii. 636). No fatal results have as yet been reported, although Auschmann has twice seen alarming collapse follow moderate doses, apparently produced by excessive vomiting (*Berl. Klin. Wochenschr.*, 1877, p. 356).*

Antagonism with Atropine.—In February, 1875 (*Brit. Med. Journ.*), Mr. Langley called attention to the antagonism existing between jaborandi and belladonna. When the heart has been slowed or arrested by jaborandi, atropine will bring the rate of pulsation almost to normal; the reverse of this also occurs, provided the amount of atropine previously applied has not been too great (Langley, *Journ. Anat.*, x. 194). Upon the sweat-glands the two drugs have also antagonistic powers, one being able to annul the action of the other (Luchsinger, *loc. cit.*). The same is true in regard to the salivary secretion (Langley). This antagonism between atropine and jaborandi is affirmed by H. Larvand

* In a case reported by Fuhrmann (*Wien. Med. Wochenschr.*, xl., 1890), one-third of a grain of pilocarpine taken hypodermically caused violent diaphoresis, salivation, lachrymation, rapid small pulse, dyspnoea, collapse. See also *Bull. et Mém. Soc. de Méd. nat.*, sér. 2, v. 28.

to extend to the intestines and pupil. In belladonna-poisoning the alkalioid has been used with no advantage in very small dose (*Lancet*, 1876, i. 346), but in a case in which nine-tenths of a grain of atropine had been taken, nine grains of pilocarpine are said to have been injected hypodermically in between one and two hours with success (Professor Purjesz, *Pest. Med.-Chir. Presse*, 1880). Dr. L. Juhász reports (*Klin. Monatsbl. f. Augenheilk.*, xx. 86) a case in which it was estimated that about one and a half grains of atropine were taken, followed in half an hour by vomiting; four and a half grains of pilocarpine were injected in about seven hours, with a favorable result. Dr. Hofferts reports (*Wien. Med. Presse*, 1883, xxiv. 1412) a case in which seven and a half grains of extract of belladonna were ingested, and nearly two grains of pilocarpine given, with recovery. For other cases of like import, see *Lancet*, vol. ii., 1890; also *Therap. Gaz.*, 1887.

LIQUOR AMMONII ACETATIS—SOLUTION OF AMMONIUM ACETATE. U.S.

Spirit of Mindererus is prepared by saturating dilute acetic acid with ammonium carbonate, and consequently consists of a solution of ammonium acetate, containing as much of free carbonic acid as the water will absorb. It is a colorless liquid, and should have no odor, or a very faint odor of acetic acid. Any specimen having an ammoniacal odor should be rejected, as containing an objectionable excess of ammonium carbonate. The taste is disagreeable and saline. As the solution upon standing undergoes decomposition after a time, it should be freshly prepared when needed.

THERAPEUTICS.—*Spirit of Mindererus* appears to be a feeble stimulant diaphoretic. Cullen has known eight ounces of it to be taken in a very short time without inducing any effect; yet the testimony is very strong as to its having some value in disease, and in *adynamic fevers* it may be employed as a diaphoretic. It is, however, much less efficient than the sweet spirit of nitre, and is probably to most persons more disagreeable than that favorite drug. Special value has been claimed for it in *dysmenorrhœa*, and even in *menorrhagia*; but I do not believe that it has any superiority over other diaphoretics in the former affection, and its being of any use in the latter disease seems apocryphal. The dose is one to two tablespoonfuls.

SPIRITUS ÆTHERIS NITROSI—SPIRIT OF NITROUS ETHER. U.S.

Sweet spirit of nitre is an alcoholic solution of *ethyl nitrite*. It is soluble in all proportions in water and alcohol, and has a neutral reaction, is a volatile, inflammable liquid, of a pale-yellow color inclining slightly to green, having a fragrant, ethereal odor, free from pungency, and a sharp, burning taste. When mixed with half its volume of official solution of potassa previously diluted with an equal

measure of distilled water, it assumes a yellow color, which slightly deepens, without becoming brown, in twelve hours. A portion of the spirit in a test-tube half filled with it, plunged into water heated to 145° and held there until it has acquired that temperature, will boil distinctly on the addition of a few small pieces of glass. Spirit of nitrous ether has the specific gravity 0.836 to 0.842, and contains 4.3 per cent. of its peculiar ether. It should not be long kept, as it becomes acid by age.

PHYSIOLOGICAL ACTION.—Undoubtedly the sweet spirit of nitre, if taken in sufficient amount, acts very decidedly upon the organism. Mr. D. R. Brown reports (*Pharm. Journ. Trans.*, March, 1857) the effects of the inhalation of sweet spirit of nitre. The first symptoms are a bluish-purple, livid discoloration of the lips and fingers, and a peculiar pallor of the face. These increase, the face assumes a ghastly look, the extremities grow cold, and the pulse becomes very weak and frequent, but the breathing remains slow and regular; muscular weakness is extreme, and the least exertion causes hurried respiration, with painful oppression in the chest, and cardiac distress. Confusion of mind and giddiness may or may not occur, but headache always comes on sooner or later. These symptoms are very similar to those caused by toxic doses of other nitrites, and it is most probable that the drug simply unites the physiological effects of the nitrites in general with those of alcohol. In sufficient amount sweet spirit of nitre is undoubtedly an active poison. Dr. Christison reports the case of a woman whose death was attributed to it, and between three and four ounces killed a child three years old in twelve hours, the symptoms closely resembling those of alcoholic poisoning with the addition of vomiting and purging (*Lancet*, 1878, ii.). In therapeutic doses it has no marked action, except in increasing the secretion of the skin and kidneys, and in a slight degree stimulating the nervous system. In children it is often of value as an antispasmodic.

THERAPEUTICS.—Sweet spirit of nitre is one of the most popular of the diaphoretics. As it exerts a stimulant action, it is useful in *adynamic* rather than in *sthenic fevers*. In children with fever offering nervous symptoms, such as starting, jerkings, etc., it is especially useful. If the patient be kept about and cool, instead of being warmly covered in bed, spirit of nitrous ether acts as a decided diuretic; but it is not sufficiently powerful to make it worthy of reliance in *dropsy*. The dose of sweet spirit of nitre is: for an adult, a teaspoonful to a tablespoonful; for a child three years old, half a teaspoonful. If a diaphoretic action is required, very minute doses should be exhibited at short intervals. Thus, for a child a year old, a teaspoonful should be put in five ounces of water, and a tablespoonful given every hour.

ALCOHOL.—As is known to every hard drinker, alcohol when taken in excess, and especially if drunk with hot water, is eliminated by the

skin, and often causes profuse sweating. As a diaphoretic it is, however, used in medicine for only one purpose,—i.e., in those cases, such as a forming "cold," *subacute rheumatism*, and *suppressed menstruation*, when a single profuse sweating is desired. In these cases I have found the following plan most efficacious, provided the patient have not decided fever: a Dover's powder is administered, and directly after this the patient goes into a hot-water or vapor bath, or else does what is known in common parlance as "soaking his feet,"—i.e., takes a pediluvium. The proper method of doing the former of these acts has been sufficiently described. In taking a foot-bath the patient should use a tub of sufficient size to enable him to place in it his feet and legs up to the knees; the water should be as hot as can be borne, and, as the feet become a little accustomed to the temperature, hotter water should be added; the immersion should continue fifteen or twenty minutes; during it, the patient, being in his night-clothes, should be well wrapped up in blankets, and at the close should be so transferred to the bed as not to get in any way chilled. After he has got to bed, and has been heavily covered with blankets, the patient should drink one or two tumblerfuls of a very hot and strong lemonade containing one, two, or three tablespoonfuls of whisky or brandy.

I think the popular belief that after a sweat there is a greater liability than usual to take cold is well founded: care must, therefore, be exercised to avoid exposure. Anointing the skin with oil of sweet almonds, or with some other equally bland fat, appears to have some power of preventing the deleterious effects of cold after sweating. More effective, however, is the application of cold to the surface of the body. The cold plunge and the cold shower which usually form the last rite in the Turkish bath appear to be what enables the habitués to go out at once into the weather without fear. In popular language, the cold "shuts the pores;" in scientific speech, it overcomes the relaxation of the surface, condensing the tissues and expelling the blood, and so stimulates the general vaso-motor nerve apparatus as to prevent the great loss of heat from the surface which would otherwise occur in a cold atmosphere.

FAMILY VI—EXPECTORANTS.

THESE are medicines possessed of the power of modifying the secretions and thereby influencing the inflammatory conditions of the respiratory mucous membranes. There are various, and even opposing, methods in accordance with which drugs act upon the pulmonary surfaces. In certain states of the latter, as in the first stages of acute bronchitis, the irritation of the part is too great for secretion, the first stage of inflammation being, as is well known, connected with suspension of function: in this condition the so-called *sedative expectorants* are indicated. These are remedies which lower arterial action: they are all nauseants, and the increase of bronchial secretion by them is analogous to that which they produce in the skin. In order to get their full effect, they must be given in nauseating doses; and if these are gradually increased until emesis is induced, the fullest therapeutic influence will be obtained. There are other drugs which may be termed *stimulating expectorants*, and which act directly upon the bronchial mucous membrane, some of them perhaps increasing secretion, but most of them rather modifying it, and some of them even diminishing it, by toning up a relaxed, over-secreting mucous membrane. Some substances which can hardly be called expectorants are nevertheless useful in bronchial diseases: thus, gallic acid will sometimes lessen the large quantities of mucus secreted in *bronchorrhœa*; or, when the mucus is tenacious in *chronic bronchitis*, alkalies may be of service by rendering the secretions less viscid, and thereby facilitating expectoration.

In many cases of disease occurring in the very young and in the very old, mucus may so accumulate in the lungs, owing to the inability of the enfeebled powers to force it up, as seriously to embarrass, or even fatally compromise, respiration. Very frequently, in acute cases of this character, such as the *suffocative catarrh* of infants, mechanical emetics are of the greatest service; but in chronic cases they induce so much disturbance of digestion as to render their use dangerous, and alcohol, ammonium carbonate, oil of garlic or of turpentine, and other drugs capable of increasing the bronchial muscular power or activity, have to be relied upon.

Again, in certain conditions of the lungs, especially in *chronic catarrhal pneumonia*, iodine and other alteratives are of great value in facilitating the absorption of exuded materials; yet these remedies can hardly be called expectorants. It may be affirmed that the value of

true expectorants in *pneumonia* of any variety is exceedingly problematic, and, except it be the ammonium chloride, they far more often do harm in the chronic pneumonias by deranging digestion than they do good by influencing the lung-tissue.

There are several substances, chief among them being morphine, hyoscyamus, chloroform, and hydrocyanic acid, which have the power of allaying cough and lessening irritation by an anodyne action. In regard to morphine, its property of checking secretion should be borne in mind, but should not prevent its use. These narcotics are especially useful when the cough is disproportionate to the amount of inflammation. When large quantities of mucus are being secreted in debilitated subjects, their use requires great caution, for fear of benumbing the nerves or nerve-centres and thereby increasing the danger of an accumulation of phlegm in the lungs.

Among the respiratory narcotics may be considered PYRIDIN,* one of the principles found in tobacco-smoke. Led by the relief sometimes afforded in asthma by the smoking of cigarettes, M. Germain Sée (*Therap. Gaz.*, 1885) made a series of clinical studies which seem to show that pyridin is of great service in *asthmatic* complaints. It is a colorless, peculiar-smelling fluid, easily soluble in water, boiling at 106.5° C., on exposure to the air absorbing water, and then boiling at a lower temperature. De Renzi states that (*Riv. Clin. e terap.*, Napoli, 1887) it decreases the pulse-rate and increases the systolic force and the blood-pressure. He even commends it in *angina pectoris* as having a superiority over digitalis and acting more quickly, and not accumulating. His (*Arch. f. Path. u. Pharm.*, xxii.) affirms that it is changed in the body into methyl-pyridyl ammonium hydroxide, but Oechsner de Coninck (*Med. Chronicle*, May, 1888) asserts that he has found it unchanged in the urine, the saliva, and the breath. In using it a fluidrachm is evaporated in a small closed chamber, and the patient allowed to breathe the air for from twenty to thirty minutes, the process being repeated three times a day. According to the experiments of Silva (*Lond. Med. Rec.*, Feb. 5, 1887), the inhalations of pyridin have the effect of diminishing the quantity of air respired in a fixed period, and of always causing abundant salivation, with coryza and general excitement.

Expectorants may be arranged under two heads,—the nauseant or sedative expectorants and the stimulating expectorants; and the general proposition may be laid down that expectorants of the first class

* Pyridin is in full dose a violent poison, producing cyanosis and general paralysis, death from failure of the respiration, with marked fall of the temperature. It appears to act upon the blood itself as to form methæmoglobin, and to be a paralyzant to the motor nerves and also to the motor centres. For discussion of general physiological action, see Helms, *Virchow's Archiv.*, cxvii., 1890; also Wertheimer and Meyer, *Arch. d. Physiol. Norm.*, ii., 1890; also Fraenkel, *Zeitsch. Klin. Med.*, 1890. It has been proposed as a practical antipyretic agent, but, on account of its tendency to disturb the blood, it seems to be a very dangerous remedy (Dreschfeld, *Med. Chron.*, 1888, and Lafleur, *Johns Hopkins Hosp. Rep.*, 1890).

are to be used in the first stages of acute bronchitis, while expectorants of the second class are to be employed in the advanced stages or in the chronic varieties of the disease. As these diseased conditions gradually merge into one another, so must the practitioner balance the ingredients of his expectorant mixtures, adapting their relations to the individual case.

The present seems a fitting place to say what is necessary in regard to the use of drugs by atomization. In this method of administration, a solution of the medicine employed is broken up by a mechanical contrivance into a fine spray and projected into the back of the mouth. There can be no doubt that when the operation is properly performed the spray reaches even the finest ramifications of the pulmonary bronchi. A discussion of this is at present scarcely necessary. Any reader having doubt upon the subject will find the evidence in the work of Dr. J. Solis Cohon (*Inhalation: its Therapeutics and Practice*, Phila., 1867).

The following rules should be attended to, to secure successful results:

1. Use the steam atomizers: all other forms of apparatus give irregular or too feeble currents, and should be discarded.
2. See that the points of the atomizing tubes are sharp and clean, —not foul, cracked, or with their edges worn.
3. See that the steam is generated equably and with sufficient force, and that the solution used is free from all solid particles, and, unless otherwise ordered, about the temperature of the body.
4. Never allow inhalations when the patient is excited, directly after eating, or immediately after exercise, unless especial circumstances, as in hæmoptysis, demand haste.
5. Have the glass mouth-speculum inserted well into the mouth, and the line of its axis and of the propulsion of the spray coincident with that of the mouth.
6. When the pharynx, or even the larynx only, is to be reached, the operation is very simple, and respiration should be natural; but when it is desired to make applications to the ultimate bronchi, the respirations should be regular, slow, and as deep and full as possible, the lungs being well emptied at expiration.
7. Do not protract the sitting until the patient is fatigued. Five minutes is generally long enough to commence with. In hæmoptysis, this rule may sometimes be departed from with advantage.
8. Let the patient give his whole attention to the matter in hand.
9. In chronic disease, one, two, or three inhalations a day are usually sufficient. In acute disease, they may be required much more often, as every hour in diphtheria.
10. Never use atomization for the purpose of general medication: it is simply a method of applying substances locally to the respiratory organs.

The substances used by atomization may be conveniently arranged as follows: *

DILUENTS.—The only diluent of any value is *warm water*. In acutely *inflamed conditions* of the *mucous membrane*, the very frequent application of water at about the temperature of 90° F. will often afford marked relief, especially in *laryngitis*.

ASTRINGENTS.—These are employed to arrest excessive secretion or hemorrhage. In their use, it must always be remembered that they are more or less irritant, and that while some persons bear them very well, in others they produce very harmful irritation; also, that the idiosyncrasies of patients vary, so that while one person will best bear a certain one of the astringents, a second may be less irritated by another drug. The rule is to try carefully until the pulmonary idiosyncrasies are known. In cases of excessive *bronchial secretion*, any irritation sufficiently severe to give origin to tightness in the chest, or to much coughing, calls for the withdrawal of the medicine. In *hæmoptysis*, a greater risk can be judiciously assumed. The astringent substances employed in this way are: First, *tannic acid*, one to twenty grains to the fluidounce of water. I have not used this; but it is said to be well adapted to cases of free secretion. Second, *alum*, varying in strength from a solution of five grains to the ounce to a saturated solution. This I have used with great satisfaction. In *hæmoptysis*, only the strongest preparation is of avail; in *bronchorrhæa*, a weak solution should be employed at first, and the strength increased *pro re nata*. One advantage this drug has over tannic acid is its compatibility with the sulphate of morphine, which should always be added to its solution when any tendency to irritation exists. In *chronic bronchitis* with excessive expectoration, I have seen alum produce most gratifying results. Third, preparations of *iron*: of these the solution of the perchloride has been used in Great Britain and on the Continent; but Monsel's solution (*Liquor Ferri Subsulphatis*) is much preferable, as even more powerfully styptic and less irritating. Ten drops of the solution may be added to the fluidounce of water and be used for the trial dose. If the lungs will bear it, and necessity exists for a stronger solution, the strength may be carefully increased up to half a fluidrachm to the ounce. *Lead acetate* is at once astringent and sedative. It has been recommended by Beigel and by Fieber in the advanced stages of acute *catarrhs*, in the proportion of three to ten grains to the fluidounce.

* Attention has been called to the inhalation of fresh, almost nascent vapors of murate of ammonia. By means of a very simple apparatus, air loaded with muratic acid vapor is drawn at each inspiration through a weak water of ammonia, and of course reaches the lung saturated with the vapors of the murate. Dr. Leberman (*Brit. and For. Med.-Chir. Rev.*, 1874, i. 519) affirms that he has employed this with the happiest results in one hundred and two cases of granular sore throat, chronic bronchitis, asthma, whooping-cough, and even angina pectoris! Most druggists, I believe, keep the inhalers.

NARCOTICS.—When there is great laryngeal or even bronchial irritation, especially in the *laryngitis* of advanced *phthisis*, half a grain of morphine, or a drachm of tincture of hyoscyamus, will often afford very great relief. It must not be forgotten that the constitutional effect of the narcotic may be produced in this way.

SOLVENTS.—As is well known, in certain respiratory affections it is very important to get rid of a false membrane, or exudation, which appears upon the mucous surfaces. Some substances seem to exert at least a degree of solvent power upon this material. Of these, lime-water appears to be the most effective and the least irritant. It should be used pure. (See article on *LIME* (*post*); also consult Meigs and Pepper, *Diseases of Children*, Phila., 1874, p. 680.)

ALTERATIVES.—In chronic *bronchitis*, and even in chronic *catarrhal pneumonia*, or *phthisis*, balsamic vapors have long been used, but atomization is not necessary in their application. *Ammonium chloride* may, however, be so applied: in chronic bronchial *catarrh* it is sometimes advantageous, and in acute *laryngitis* inhalations of a warm saturated solution of it are often very useful. In chronic *laryngitis*, silver nitrate may be exhibited by atomization, but it is, I think, much better to apply it directly by means of the laryngoscope and the brush or probang. In cases of *fetid expectoration*, carbolic acid in weak solution (gtt. i-ii to f3i) may be used as an antiseptic and alterant.

NAUSEATING EXPECTORANTS.

The three nauseating expectorants are ipecacuanha, tartar emetic, and lobelia. As these substances are sufficiently discussed elsewhere in this work, it remains only to say a few words in regard to their comparative use as expectorants.

LOBELIA is used only when the inflammatory action is complicated with a tendency to spasm of the bronchial muscles. It is too powerfully depressant to be given to children with safety. The best expectorant preparation is the *tincture* (*Tinctura Lobeliae*, U.S.). The ordinary expectorant dose of this is twenty to thirty drops, usually given in combination every three hours. When a very decided impression is desired, as in some cases of asthma, one fluidrachm may be exhibited every two hours until vomiting is produced or relief obtained. Under these circumstances, the patient should be closely watched, as lobelia in these large doses sometimes causes very alarming symptoms.

IPECACUANHA is the safest and most used, although perhaps the least powerful, of all the nauseating expectorants. It is the only one that should be given freely to children. In the early stages of all acute

inflammatory conditions of the respiratory mucous membranes it is of great service. The preparation most generally used in acute *bronchitis* is the *syrup*, the dose of which is from twenty drops to a teaspoonful every two, three, or four hours, according to the exigencies of the case. Any of the other liquid preparations of *ipecacuanha* may be employed in a corresponding dose. The *troches of ipecac* (*Trochisci Ipecacuanhæ*, U.S.) each contain about one-quarter of a grain of *ipecac*, and may be employed in catarrhal complaints. The *troches of morphine and ipecac* (*Trochisci Morphinæ et Ipecacuanhæ*, U.S.) contain each the fortieth of a grain of sulphate of morphine and the twelfth of a grain of *ipecac*,* and may be used when an anodyne effect is desirable.

TARTAR EMETIC is much more powerful than *ipecacuanha* as a sedative and nauseant, and must be used with more care. It is the most efficient of all the sedative expectorants, and affords in cases of urgency a very efficacious, although a very disagreeable, method of putting an end to an attack of acute *bronchitis*. I have known of a public speaker, who had risen in the morning completely overwhelmed with bronchitis, enabled to deliver his evening speech by the judicious use of tartar emetic. To effect this rapid relief, one-twelfth of a grain of tartar emetic should be taken every ten or fifteen minutes until it induces profuse vomiting. After the nausea is past, the system may be toned up for exertion by a lunch of ale and oysters. Tartar emetic is a powerful remedy, and is especially injurious to young children, in whom it is very apt to induce collapse. It is therefore contra-indicated by infancy, as it also is by the existence of gastro-intestinal inflammation. The dose as an expectorant is from one-twelfth to one-quarter of a grain, repeated according to circumstances.

GRINDELIA. U.S.

This is the leaves and flowering tops of *Grindelia robusta* and of *Grindelia squarrosa*, plants inhabiting the extreme western portions of North America. In commerce the whole herb, including the stems, roots, and floral heads, is employed. The taste is warmish, peculiar, and very persistent. It has been affirmed by Dr. Rademacher to contain an oil, a resin, and a crystalline alkaloid, but further chemical investigation of it is urgently required. When taken internally in sufficient dose it is said to produce a sense of warmth in the stomach, owing to its local stimulant influence.

We are indebted to Dr. Buffington and Dr. V. B. Dobroklowski for what knowledge we have of the physiological action of *Grindelia*. Unfortunately, their results are known only through abstracts. (See *Centralbl. f. Med. Wissens.*, xxiii., 1885; *Amer. Journ. Med. Sci.*, Jan. 18, 1886; *Lond. Med. Rec.*, March, 1886.) The drug appears to have very feeble toxic powers, three drachms of the fluid extract being required to kill rabbits. So far as the nervous system is concerned, according

to Dr. Buffington, *grindelia* first paralyzes the peripheral nerves of sensation, next the sensory side of the spinal cord, and finally involves the motor nerve-trunks and the motor side of the cord. The occurrence of narcosis with dilated pupils indicates that there is also an influence exerted upon the cerebrum. In warm-blooded animals, according to the same investigator, there is slowing of the action of the heart by stimulation of the inhibitory apparatus, and elevation of the blood-pressure by stimulation of the vaso-motor centre. The results achieved by Dobroklowski do not seem altogether to accord with these statements, as he found that both small and large, but not toxic, doses, increased the pulse-rate as well as the arterial tension: after toxic doses both pulse-rate and arterial tension fell, the heart being finally arrested in diastole. These phenomena were not affected by isolation of the heart from the nervous system by the previous use of atropine or by vaso-motor paralysis through division of the spinal cord, and the isolated frog's heart was arrested by the drug. Dr. Dobroklowski further found that the drug acts upon the motor nerves and the muscles.

THERAPEUTICS.—*Grindelia* has not been employed for its effect upon the circulation, and in the doses used in medicine it appears to exert no distinct influence upon the heart or arteries. It has been largely used, often with alleged excellent results, in *asthma*, and in *bronchitis*, associated with a tendency to bronchial spasm. It is probable that in these cases it not only has a relaxing influence, but also stimulates the mucous membrane, and even in *chronic bronchitis*, especially of the aged, it is said to do good. It has also been employed in *whooping-cough*. Its active principles are probably excreted by the kidneys: hence after large doses there are sometimes evidences of renal irritation, and in *chronic catarrh of the bladder* good has been effected by its stimulant influence upon the mucous membrane of the viscus. It has also been employed as a local application, with alleged good results, in *vaginitis*, applied either in the form of a poultice or in solution. The only preparation for internal use is the *fluid extract* (*Extractum Grindeliæ Fluidum*), of which the dose is twenty to sixty minims. The fumes of burning *grindelia* are also sometimes inhaled with alleged relief by *asthmatics*. The plant should be steeped in a solution of nitre, dried, and burnt upon a plate, or may be smoked in cigarettes or in a pipe.

STIMULATING EXPECTORANTS.

AMMONII CHLORIDUM—AMMONIUM CHLORIDE. U.S.

Ammonium Chloride, *Muriate of Ammonia*, or *Sal Ammoniac*, is prepared by heating with sodium chloride the ammonium sulphate, which is obtained from gas-liquor by the addition of sulphuric acid. *Gas-liquor* is a water which has been used to wash ordinary burning gas, and contains largely of ammonium carbonate, hydrocyanate, hydrosul-

phate, and sulphate. *Ammonium sulphate* is not itself employed as a medicine, but is official, because the other preparations of ammonia are made from it.

Muriate of ammonia is a white, translucent, fibrous, and tough salt, free from odor, but having a sharp, saline taste. It occurs in large concavo-convex plates, dissolves in three parts of cold and in one part of boiling water, and at a red heat sublimes without decomposition.

PHYSIOLOGICAL ACTION.—When applied in a solid form, or in a concentrated solution, ammonium chloride acts as an irritant upon raw surfaces and upon mucous membranes. This influence seems, however, not to be sufficiently powerful to enable the drug in any dose to produce lethal poisoning: at least, Oesterlen (*Heilmittellehre*, Tübingen, 1851) states that one of his patients took two ounces of the salt without suffering any more severe results than colicky pains and some diarrhoea.

If some of the older experimenters are to be credited, its influence upon the lower animals is more powerful. In the experiments of Dr. Smith (quoted by Stillé), two drachms of the salt applied to the wounded thigh of a dog caused death in from twelve to thirty-six hours, and, according to Orfila, the same quantity dissolved in two ounces of water and introduced into the stomach of a dog caused violent convulsions, with great tetanic rigidity, and finally death. Arnold (Wibmer, *Die Wirkungen der Arzneien und Gifte*, Munich, 1831, Bd. i. p. 143) found that thirty grains will kill a rabbit in ten minutes. On the other hand, in the more recent studies of Dr. Rabuteau (*L'Union Médicale*, 1871, p. 330), half a drachm injected into the veins of a moderate-sized dog had no apparent effect, while one drachm only produced muscular weakness, deepening into temporary paralysis of the hind legs, vomiting without diarrhoea, and general prostration for four or five hours.

The chief interest of the clinician in the physiological action of muriate of ammonia centres in its effects when given continuously for some time. The older writers upon the subject assert that its influence on the heart is a sedative one, but that it increases the capillary circulation (Sundelin, *Heilmittellehre*, Band i. p. 150, Berlin, 1853). This opinion appears to me to be founded chiefly upon speculation and inference, and not to have any sufficient basis. Whatever may be the action of very large amounts, I have never been able to perceive that muriate of ammonia given in ordinary doses has any decided influence upon the circulation. According to Sundelin and other authorities, the drug when given freely and continuously produces a profound impression upon the blood itself, lessening its plasticity and impairing its constitution. One case of profound and otherwise inexplicable prostration and typhoid condition, which occurred in a patient who was taking nearly a half-ounce of muriate of ammonia per diem, has come under my own notice; and Dr. Isham reports (*Med. News*, xl. 455) a

case in which an eruption of bloody blebs, with hæmaturia, hæmorrhages from mucous membranes, and great prostration, was apparently produced by the prolonged use of the salt. The elaborate analyses of F. W. Böcker (*Beiträge zur Heilkunde*, Bd. ii. p. 170, Crofeld, 1849), although somewhat discordant, indicate that sal ammoniac does impoverish the blood, since in some instances there was a decided decrease in the solids. Arnold (*loc. cit.*) also noticed that in dogs poisoned with muriate of ammonia the blood contained less than the normal percentage of solids. In accord with this reputed action on the blood is the effect of the drug upon the urinary secretion. In a very elaborate series of experiments, Böcker (*loc. cit.*, p. 158) found that, given to a healthy man, sal ammoniac increased very notably all the solids of the urine, except the uric acid, which was very slightly diminished; and Rabuteau, in an investigation in which, by identity of diet, etc., all sources of fallacy were as far as possible excluded, found that the excretion of urea was very decidedly increased.

The opinion has long prevailed that the muriate of ammonia especially affects the mucous membranes, and Böcker believes that in them it hastens very greatly the nutritive changes and the exfoliation of epithelium. Clinical experience has, I think, demonstrated that the drug does act especially upon the mucous membranes; although it is very difficult to bring forward any definite tangible proof of this.

The muriate of ammonia, when ingested, probably enters into all the excretions, since Rabuteau (*L'Union Méd.*, t. xii. p. 329, 1871) has found it in the saliva. The same observer has shown that the chief elimination takes place through the kidneys, since he found in the urine almost all of the salt that had been taken.

THERAPEUTICS.—In the last century chloride of ammonium was very extensively used in *intermittent fever*; but at present the salt is rarely or never employed, although Aran (*Bulletin Thérap.*, t. xii. p. 344) has attempted to revive the practice, and asserts that he has had very good effects resulting from it,—in thirteen cases of intermittent fever curing, by the exhibition of two drachms a day, seven at once, four after the second paroxysm, one after the third, and one after the fourth. The chief present use of the muriate of ammonia is as a remedy in *acute* and in *chronic bronchitis*: in the first variety of the disease the drug should not be exhibited in the first stages; but after active inflammatory action has been subdued by the sedative expectorants, it is very useful. It is very largely employed in the *catarrhs* of young children, and is often of great service. In Germany the remedy has been extensively exhibited in *gastric* and *intestinal catarrhs*. Dr. W. Stewart,* as the result of a large experience, highly commends its use in *chronic torpor* of the liver, *chronic hepatitis*, and *hepatic abscess*.

* Chloride of Ammonium, Rangoon, 1870; *Madras Monthly Journ. Med. Sci.*, Feb. and March, 1872; *Indian Med. Gaz.*, Dec. 1872; *Philad. Med. Times*, viii. 316.

In the first of these affections I have employed it to a limited extent, with very good effects. Dr. Stewart gives twenty grains of it three times a day, and continues its use for weeks or even months.

In various *neuralgias*, especially in the *ovarian* variety, but to a less extent in *migraine* and other forms, sal ammoniac has been largely employed for the purpose of relieving pain. Thirty grains of it are given in combination with from two to five drops of tincture of aconite root, and the dose is repeated in half an hour, if necessary.

ADMINISTRATION.—The usual dose of the muriate of ammonia in catarrh is from five to ten grains three or four times a day. This dose is given in a tablespoonful of water, to which, for the purpose of concealing the taste, from five to ten grains of liquorice may be added. The *troches* (*Trochisci Ammonii Chloridi*, U.S.) contain one and a half grains each, and are used as a local stimulant to the fauces and the epiglottis.

SENEGA—SENEGA. U.S.

The root of *Polygala Senega*, a small, herbaceous perennial, indigenous to the Middle and Southern United States. The root is several inches long, very much contorted, of a peculiar feeble odor, and a taste at first sweetish but afterwards acrid. It is distinguished by a keel-like line, shorter than the root, and presenting the appearance as if a string were drawn tightly under the bark from end to end. Quevenne discovered in senega a peculiar principle which he named *Polygalic Acid*, although he thought that it was closely allied to saponin. There has been much discussion among chemists, but it now seems probable that polygalic acid or *senegin* is distinct from *saponin*, a glucoside first found in the root of *Saponaria officinalis*, but known to exist in a great many plants.*

THERAPEUTICS.—Senega is chiefly used as a stimulant to the mucous membrane of the lungs in *chronic bronchitis* and in the very advanced stages of the acute disorder. It is believed to be one of the most stimulant substances of its class, and is therefore contra-indicated by acute pulmonary inflammation, and is indicated by a relaxed state of the bronchial mucous membranes. If its stimulant effect be modified by combination with tartar emetic, it may be given in acute bronchitis at an earlier stage than it could be used by itself. Senega is locally irritant, and, when administered in large doses, produces vomiting, which is probably reflex in its origin. In overdoses it not only vomits, but also purges: it is, however, never used for these purposes. Senega has been employed as an emmenagogue in *amenorrhœa* and as a diuretic in *dropsy*, but has achieved no permanent reputation in these disorders. The *fluid extract* (*Extractum Senegæ Fluidum*, U.S.,—dose, ten to fifteen drops) is official, but the *syrup* (*Syrupus Senegæ*, U.S.,—dose, a fluidrachm) is usually employed.

* For an elaborate chemical and physiological study, see Atlar (*Arbeit. d. Pharmakol. Inst. z. Dorpat*, 1888, i.).

AMMONIACUM—AMMONIAC. U.S.

The concrete juice of an umbelliferous plant, *Dorema Ammoniacum*, a native of Persia. It is said to exude from punctures made in the plants, and also to be obtained by a process similar to that employed in the case of *asafetida*. It is a gum resin, containing a little volatile oil, and occurs in commerce as irregularly globular yellowish tears, from the size of a pin to that of a large chestnut, hard and brittle when cold, and breaking with a smooth resinous fracture; and in irregular mottled masses, composed in part of tears, and containing many impurities. The odor is faint and disagreeable, the taste bitterish, sweetish, and somewhat acrid.

THERAPEUTICS.—The influence of ammoniac upon the general system is very slight. It is a local irritant, and therefore in large doses is capable of producing vomiting and purging. It was formerly employed as a nervous stimulant, but its internal use is now restricted almost exclusively to *chronic bronchitis* with either deficient or excessive secretion. The dose of ammoniac is twenty to thirty grains; of the emulsion (*Emulsum Ammoniaci*—4 per cent., U.S.), one to two table-spoonfuls. *Emplastrum Ammoniaci cum Hydrargyro*, U.S., contains mercury and sulphur, and is employed as a local stimulant, alterative, and discutient in *scrofulous* and *syphilitic swellings, enlarged joints, etc.*: its external use is said to have caused salivation.

SULPHURETTED HYDROGEN.

As a sequence to the bacillus theory of phthisis, in July, 1880, Dr. Bergeon proposed before the French Academy of Science a method of treating tuberculosis, the central idea of which is the injection of sulphuretted hydrogen gas diluted with pure carbonic acid into the large intestine. The apparatus employed consists of a large caoutchouc bag, filled with carbonic acid gas, connected with a Woulfe's bottle, which is in turn united to a tube, the other end of which is inserted into the rectum of the patient, so that by compressing the bag the carbonic acid is forced to bubble through a solution of sulphuretted hydrogen, natural or artificial, and pass into the intestine. Bergeon preferred natural sulphur-water, but artificial solutions have been used much more extensively. In the Hôpital Cochin the following solutions were employed, fifteen cubic centimetres of No. 1 being used at one *séance*.

SOLUTION No. 1.—Sulphide of sodium, pure, ten parts by weight, distilled water, enough to make one hundred parts by weight.

One cubic centimetre of this liquid disengages exactly ten cubic centimetres of sulphuretted hydrogen, when there is added to it one cubic centimetre of the following solution (No. 2):

SOLUTION No. 2.—Acid tartaric, twenty-five parts by weight; acid salicylic, one part by weight; distilled water, one hundred parts by weight.

In the Philadelphia Hospital from three to five pints of carbonic acid were forced through a solution of ten grains each of sodium chloride and sulphide,—hydrogen sulphide being formed by the reaction between the calcium sulphide and the carbonic acid: thus, $\text{NaS} + \text{CO}_2 + \text{H}_2\text{O} = \text{NaCO}_3 + \text{H}_2\text{S}$. It is plain that the amount of hydrogen sulphide received by the patient must be very variable even with the Hôpital Cochin solution, while the plan adopted in Philadelphia is still more unsatisfactory. According to M. Morell, twenty-five cubic centimetres is the dose of the gas. In over-amounts sulphuretted hydrogen acts as a deadly poison, and in the hospital of the University of Pennsylvania a quart of a mixture containing equal quantities of carbonic acid and sulphuretted hydrogen injected into the rectum caused in three minutes unconsciousness, with scarcely perceptible respirations at the rate of one hundred a minute, and imperceptible pulse, symptoms subsiding in fifteen minutes under artificial respiration and other treatment.

There is no proof that sulphuretted hydrogen is poisonous to the tubercle-bacilli, and, after an extraordinary but very temporary popularity, the Bergeon treatment of phthisis has fallen into desuetude. My own experience, however, has led me to the very positive belief that sulphuretted hydrogen may be very useful in the treatment of various *catarrhs*, and that when in *phthisis* expectoration is very free it may do much good, not by curing the original pathological process, but by alleviating the *catarrh* caused by this process. In chronic *bronchitis* with expectoration, in *catarrhal pneumonias*, and in *asthma* with much bronchial inflammation, sulphuretted hydrogen is a valuable remedy. My own experience is also quite positive that when administered persistently for months it may be of service in chronic *gout*. It is probably also useful in many cases of *skin-disease*. It is in these affections of the mucous membranes and of the skin, and in the gouty diathesis, that the so-called sulphur springs have been used from time immemorial by innumerable patients. The method of administration employed by Bergeon is barbarous and possesses no advantages whatever. Under it, it is impossible to determine exactly how much sulphuretted hydrogen is exhibited, while in most cases the colon is more sensitive than is the stomach to the local action of the drug. A much better method is the exhibition of sulphuretted hydrogen by the mouth, either in the form of the natural sulphur-waters, or, as I have employed it, by means of water saturated with sulphuretted hydrogen and carbonic acid gas. This water is very readily prepared by a small apparatus, is not objected to by most patients after the first day or two of its taking, and usually does not disagree with the stomach; although there are cases in which it causes so much abdominal disturbance that its use has to be abandoned. The dose of the saturated solution is two to four ounces three or four times a day. After the larger doses the odor of the gas upon the breath becomes very perceptible.

OLEUM SANTALI, U.S., *Oil of Sandal Wood*, is a pale-yellowish, strongly-pungent, aromatic, and spicy volatile oil, obtained from the wood of the *Santalum album*. It is a stimulant or irritant to the various mucous membranes, and while its general action upon the system is not known, it is a very valuable remedy in *chronic bronchitis* and in the advanced stages of *acute bronchitis*, and also in the advanced stages of *gonorrhœa*. It seems to be more stimulating than the oil of eucalyptus, and rather less so than terebene. From ten to twenty drops may be given every three or four hours in capsules, emulsions, or on sugar.

BALSAMUM PERUVIANUM, U.S., *Balsam of Peru*, is obtained from *Toluifera Pereira*, a tree of Central America, by making incisions in places which have been previously beaten with clubs, slightly burning them, catching the juice in old rags, and finally boiling these in water and skimming off the balsam as it rises to the surface. This balsam is a viscid, honey-like, fragrant, brownish fluid, of a warm, bitterish taste, which has been shown by Brautigan and Nowack (*Centralb. Klin. Med.* xxiv., 1889) to be practically devoid of antiseptic properties. According to Frémy, it contains not benzoic, but cinnamic acid. It has been used in *chronic catarrhs* of the respiratory and the genito-urinary system, in doses of half a fluidrachm.

BALSAMUM TOLUTANUM, U.S., *Balsam of Tolu*, is obtained from *Toluifera Balsamum*, a tree very closely allied to that which yields the balsam of Peru. The incisions, however, are not burnt, and the juice is simply caught in vessels. Balsam of Tolu is at first a thick, viscid fluid, but by time it is converted into a hard, translucent, resinous solid. Its odor is highly fragrant, and its taste vanilla-like. It contains cinnamic acid and a volatile oil, and its medical properties are the same as those of the balsam of Peru. On account, however, of its grateful taste, it is preferred to the latter, and is very much used to flavor medicines, especially cough-mixtures. In large doses (gr. xx to gr. xxx every three hours) it may be of some value in *chronic bronchitis*, but as generally used its preparations are simply agreeable vehicles. The dose of the tincture (*Tinctura Tolutana*—10 per cent., U.S.) is one-half to one fluidrachm; of the much more frequently used syrup (*Syrupus Tolutanus*, U.S.), half a fluid ounce.

ALLIUM, U.S., or *English Garlic*, the clove of *Allium sativum*, contains a volatile oil, which is a stimulant in small doses to digestion, and is also a stimulating expectorant often of very great service in advanced stages of *bronchitis*. It is in lingering, deep-seated "colds" that I have derived especial benefit from its use. It is also very valuable in the *acute bronchitis* of infants, when the powers of the system begin

to give out. The oil of garlic is further believed to have the ability to stimulate the expulsive function of the small bronchial tubes, and is certainly a powerful rubefacient and a decided nervous stimulant. For these reasons, garlic poultices are a favorite application in the acute *suffocative catarrh* of infants, and are not rarely applied to the spine, legs, and feet in general *infantile convulsions*. They are made by simply reducing the garlic to a pulp by pounding. When a continuous application is desirable to the delicate skin of an infant, as in catarrh, it is generally necessary to reduce their strength with flaxseed meal. The dose of the *syrup* (*Syrupus Alhi*, U.S.) for a child a year old is one fluidrachm.

SCILLA, U.S., or *Squill*, is one of the most used of the stimulating expectorants, coming especially into play in the advanced stages of ordinary *bronchitis*. The *syrup* (*Syrupus Scillæ*, U.S.) is the favorite expectorant preparation. As it contains acetic acid, it is incompatible with ammonium carbonate. The *Compound Syrup of Squill* (*Syrupus Scillæ Compositus*, U.S.: fld. ext. of squill, of senega, aa eighty parts; tartar emetic, two parts in every one thousand) contains one grain of tartar emetic to the ounce, and is therefore sedative to the circulation, although stimulant to the bronchial mucous membrane. It is, of course, in large doses a powerful emetic; and, under the name of *Coze's Hive Syrup*, it has been much used in the domestic treatment of *croup*. The dose of the simple syrup is one-half to one fluidrachm; of the compound, twenty to forty drops; as an emetic to children, ten drops to a fluidrachm, according to age, repeated every twenty minutes until it operates.

PIX LIQUIDA, U.S.—*Tar* is a black semi-liquid substance, of peculiar odor and taste, obtained by the destructive distillation of various species of pine. The tar used in this country is almost exclusively the product of the *Pinus palustris* of North Carolina and other of the Southern States. In composition it is very complex, containing pyroligneous acid, creasote, empyreumatic oil, and a number of more or less peculiar principles. When distilled, it yields an oily liquid, known as *oil of tar*, and a solid, black residue, *pitch*. It is freely soluble in alcohol, ether, and the fixed and volatile oils, and also to a slight extent in water.

PHYSIOLOGICAL ACTION.—As tar contains a notable proportion of creasote, if taken in sufficient quantity it is capable of exerting the peculiar influence of that agent upon the system. But creasote is not the only active principle in it: hence tar differs from that drug in acting more than it does upon the mucous membranes. That tar is capable of acting as a poison is shown by the case reported by Taylor (*Principles and Practice of Medical Jurisprudence*, 2d ed., vol. i. p. 334), in which death resulted in a man from taking by mistake the oil of tar. To cause death, tar itself would have to be ingested in enormous quantity,

since a sailor (according to Stillé) is said to have recovered after taking between a pint and a quart of it.

Applied to any part, tar acts as a very decided stimulant.

THERAPEUTICS.—Tar is used internally almost solely as a stimulant expectorant in the advanced stages of obstinate *acute bronchitis*, or in *chronic bronchitis*. Its chief use in medicine is in chronic diseases of the skin, as a stimulant application in the form of the officinal ointment (*Unguentum Picis Liquidæ*, U.S.,—equal parts). In many cases this is too severe, and the strength must be reduced. Professor Hebra states, in his work on diseases of the skin, that if it be applied too freely enough of the tar may be absorbed to darken the color of the faces and the urine, and even to cause gastric irritation and black vomit. *Tar Water* may be used internally, in doses of half a fluidounce to one fluidounce; a better preparation is the *Syrup of Tar* (*Syrupus Picis Liquidæ*—7.5 per cent., U.S.),—dose, one to two fluidrachms.

For a study of **EUCALYPTUS** and of **TURPENTINE** as expectorants, see General Articles upon these subjects.

TEREBENUM, U.S.—*Terebene* is a clear, colorless liquid, insoluble in water, isomeric with turpentine, and of a peculiar odor, somewhat resembling that of freshly-sawed pine wood. It is prepared by adding drop by drop to any convenient quantity of oil of turpentine five per cent. of its weight of U.S.P. sulphuric acid. The mixture must be kept cool, allowed to stand in a porcelain capsule so as to be exposed thoroughly to the air for twelve or eighteen hours, and distilled at a temperature not above 160° C.

Terebene is a valuable stimulant expectorant, first recommended by Dr. William Murrell (*Brit. Med. Journ.*, Dec. 1885) in that form of *chronic bronchitis* often known as *winter cough*. It is very useful not only in cases of chronic bronchitis, but also in the *acute* disease after the earlier stages have passed by. As an expectorant it is nearly equivalent to the oil of eucalyptus, but is, perhaps, a little more stimulating. It probably exerts upon other mucous membranes the same action that it has upon that of the lungs, and has been employed with asserted good results in *dyspepsia*, especially in the flatulent intestinal variety, and may be used in chronic or subacute *inflammations of the genito-urinary tract*. Its action upon the general system has not, that I am aware of, been investigated, but probably resembles that of oil of turpentine. It cannot be given in watery solution, and the method sometimes practised of dropping it on sugar is improper, on account of its being apt to make with sugar a tough, insoluble mass. It should be administered in emulsions, or preferably in capsules. From twenty to forty minims of it may be given to the adult in the course of twenty-four hours. It has also been used by Dr. Murrell by atomization with asserted good results.

FAMILY VII—EMMENAGOGUES.

EMMENAGOGUES are medicines which are employed to promote the menstrual flux. As the stoppage, scantiness, or non-appearance of this secretion arises from very different causes, and as these causes are of diverse or even opposite natures, and may often be removed by drugs, it is obvious that very many remedies of very different character are indirect emmenagogues. Thus, amenorrhœa may depend upon plethora, or it may be the result of anæmia; and while in the one case depletory medicines are indicated, in the other case tonics are no less essential. Besides these indirect emmenagogues, there are other substances which appear to act directly as stimulants to the uterine mucous membrane; and indeed it is probable that many of the indirect emmenagogues possess more or less of this power. The emmenagogues may be conveniently arranged in three groups,—the tonic emmenagogues, the purgative emmenagogues, and the stimulant emmenagogues.

TONIC EMMENAGOGUES.

IRON is the most prominent member of this section of the emmenagogues. By far the larger number of cases of amenorrhœa are associated with, if not dependent upon, anæmia, and are benefited by the use of iron. It should be given in full tonic doses until the anæmia is relieved or the powerlessness of the remedy to effect such change is demonstrated. It is very rarely proper to rely solely upon the iron, which in the great majority of instances should be combined with more decidedly active emmenagogues.

MYRRH has some reputation as a tonic emmenagogue, but, as it is always employed in combination with other more active medicines of its class, the rôle it plays is somewhat uncertain. It should be used only in atonic uterine conditions, and is said to be especially valuable when chronic pulmonary complications exist. The preparations of it most used in amenorrhœa are the compound pills of iron, the compound mixture of iron, and the pills of aloes and myrrh.

PURGATIVE EMMENAGOGUES.

ALOES is believed by some to act as an emmenagogue solely by virtue of its stimulant action upon the rectum, but it very probably directly

affects the uterine mucous membrane. Be this as it may, it is a stimulant emmenagogue, especially useful when *atonic amenorrhœa* exists with constipation. Ordinarily it should be given in repeated doses (three times a day) of such size as will produce daily one or two soft, semi-liquid stools. At the menstrual period advantage may be sometimes derived from the administration of a full purgative dose. It is almost always given in combination, especially with iron, whose tendency to constipation it obviates. In *plethoric amenorrhœa*, when torpidity of the bowels is present, salines, and not aloetic purgatives, should be employed.

BLACK HELLEBORE has been used by some as a purgative emmenagogue, but is now very rarely if ever employed. From twenty drops to a fluidrachm of the tincture may be given three times a day.

STIMULATING EMMENAGOGUES.

SABINA—SAVINE. U.S.

The dried tops of *Juniperus Sabina*, a juniper, native of the south of Europe and the Levant, but very similar to our native species, the *Juniperus Virginiana*, or red cedar. The active principle is a pale or dark yellow, when highly rectified colorless, volatile oil (*Oleum Sabina*, U.S.), which has a strong terebinthinate odor and burning taste.

The oil of savine is a powerful local stimulant, causing burning and redness when applied to the skin, and is capable of producing fatal gastro-intestinal inflammation. Taken internally in minute doses, its effects are confined to a sense of warmth, with perhaps some ill feeling in the stomach, and slight acceleration of the pulse. After larger amounts, the arterial excitement is more pronounced, and is accompanied by an increased frequency of urination, and sometimes, also, by an actually increased flow of urine. The symptoms induced by poisonous doses are: severe abdominal pain; incessant vomiting and bloody purging; diminution or even suppression of the urine, which is often albuminous and bloody; disordered respiration; symptoms of disturbed innervation, such as unconsciousness, stertorous breathing, convulsions or convulsive tremblings; the scene closing by death in collapse. In pregnant females, abortion, accompanied by violent flooding, almost always occurs before the fatal issue. After death, signs of gastro-intestinal inflammation are generally present, but in some instances these are wanting, and in one case reported by Dr. Letheby (*London Lancet*, 1845) pulmonary apoplexy and congestion of the brain were the chief lesions. Taken in small, repeated doses, savine is a powerful stimulant to the uterine system, and may be used as such in *atonic amenorrhœa*. Its powers in *menorrhagia* dependent upon a relaxed state of the uterine tissues are even more pronounced. Its use as an *abortifacient* is accompanied by the gravest dangers to life. In uterine disease of a sthenic type savine is strongly contra-indicated. The dose of

EMMENAGOGUES.

the oil (*Oleum Sabinæ*, U.S.), the only preparation which should be used, is from five to ten drops, repeated every three or four hours; of the fluid extract (*Extractum Sabinæ Fluidum*, U.S.), the dose is from three to eight minims.

RUTA—RUE.

The leaves of *Ruta graveolens*, or common garden rue, an under-shrub of the south of Europe. Rue has a strong peculiar odor, a warm, bitter, acrid taste, and is dependent for its medical properties upon a peculiar volatile oil, although it also contains a crystalline neutral body, *Rutin*.

The influence of rue upon the system is similar to, but less decided than, that of savine. Locally it is an irritant, producing, when applied to the skin persistently or in a concentrated form, such as the oil, burning, redness, and vesication. According to M. Hélie, taken internally, in large doses, it causes violent gastric pains, excessive and sometimes bloody vomiting, profuse salivation and swelling of the tongue, great prostration, confusion of mind, and convulsive twitchings, with, in pregnant women, abortion. Rue has been, and probably still is, employed in Europe for the production of criminal abortion, and, although its use for this purpose certainly endangers life, I have met with no record of a fatal case. Indeed, the only death from rue that I am cognizant of occurred in a man weakened by dysentery (case, Dr. G. F. Cooper, *Med. Examiner*, N. S., ix. 720). Like savine, it is employed both in *amenorrhœa* and in *menorrhagia* when dependent upon uterine atony; and especial advantage has been claimed for the combination of it with savine. Owing to the aromatic properties of its oil, it has been used somewhat as a *carminative*. The oil, the only proper preparation, may be used in doses of from three to six drops every three or four hours.

PETROSELINUM—PARSLEY.

The root of *Petroselinum sativum*, or common parsley. It contains a peculiar, non-nitrogenous, liquid, neutral principle, *Apiol*, which resembles somewhat the fixed oils, but is not saponifiable; a glucoside, *Apiaïn*, and a volatile oil.

PHYSIOLOGICAL ACTION.—The volatile oil of parsley has probably the same physiological and therapeutic value as the more ordinary essential oils, and according to Mitscherlich very large quantities of it (half an ounce) will produce death in the rabbit, largely, no doubt, owing to its local irritant action. The chief interest of parsley to the physician centres in *apiol*. According to the discoverers of this principle, MM. Joret and Homolle (*Journal de Pharmacie*, 3e série, xxviii. 219), one gramme of it will produce in man a cerebral excitation very similar to that induced by coffee, without other symptoms. In doses of from two to four grammes it causes a species of intoxication, with

vertigo, ringing in the ears, and severe frontal headache,—a group of symptoms very similar to those seen in cinchonization.

THERAPEUTICS.—Apiol was introduced by its discoverers as a remedy in intermittent fever, over which, they asserted, it exercised a control secondary only to that of quinine. A commission of the Paris Society of Pharmacy reported that it would cure about half the cases of quotidian and tertian, but was powerless against the quartan; also, that a return of the paroxysm was more common after apiol than after quinine. Clinical experience subsequent to these experiments has demonstrated that the drug has some power over malarial disease, but is very inferior to quinine. Joret and Homolle also employed the drug in *intermittent neuralgia*, and in *amenorrhœa* as well as in *dysmenorrhœa*. Joret (*Bulletin Thérap.*, Feb. 1860) has recommended apiol very highly in the last two affections, and his results have been confirmed by Marotte (*Ibid.*, t. lvi., 1863) and other writers. When there was very decided plethora, the apiol was thought by Marotte not to be so efficacious as at other times. In any case of amenorrhœa dependent upon or associated with anæmia or other systemic vice, the continuous administration of iron, tonics, or other suitable medicines must not be neglected. The apiol is given not between the menstrual periods, but just before the latter. Joret and Homolle believe that small doses (three grains twice a day) of it should be exhibited for the week preceding the expected return of menstruation. If any symptoms of the menstrual molimen appear, fifteen grains of it may be administered in the course of a few hours; or they may be given daily for two or three days at the expected time. In intermittent fever, the same quantity may be exhibited four or five hours before the expected paroxysm. On account of its exceedingly disagreeable taste, apiol is always administered in capsules, one of which, as imported from France, usually contains the fourth of a gramme (gr. 3.9).

POTASSIUM PERMANGANATE, originally recommended by Professor Sydney Ringer as an emmenagogue, has been very highly commended by Dr. Fordyce Barker and other physicians (see *Therap. Gaz.*, vols. ii. and iii.). According to Dr. Barker, the permanganate is not to be employed when menstruation has been arrested by grave constitutional or local disease, or suddenly by cold, moral shock, or acute disease. Professor Ringer says that the permanganate has no power of originating uterine contractions, but other clinicians attribute to it abortifacient properties, and cases are reported in which abortion has followed its administration (see J. L. Watkins, *Therap. Gaz.*, vol. ii. S. B. Sperry, *Ibid.*, vol. iii.).

Therapeutic doses of the permanganate must be entirely decomposed in a very short time after they reach the stomach, so that any action which the drug exerts upon the general system is due to the oxide of manganese; indeed, the ordinary black oxide of manganese is affirmed

by various practitioners to be as active an emmenagogue as is the permanganate. I have employed these agents to a limited extent in functional *amenorrhœa*, sometimes with, sometimes without, success. The only difference which I have been able to perceive in their action is that the permanganate is the more irritant to the stomach. The dose of either preparation may be set down as one or two grains,—always administered after meals, in order to avoid, as far as possible, gastric irritation. Cases of severe gastritis produced by the permanganate have been reported (*Therap. Gaz.*, vol. iii., 1887).

CANTHARIDES is a very decided uterine stimulant, and is much used as an ingredient of emmenagogue mixtures. From three to five drops of the tincture may be given three times a day; if no unpleasant symptoms arise, the dose may be cautiously increased to six drops, the production of strangury being, of course, sedulously avoided.

GUAIAC, as an emmenagogue, is much less stimulating than cantharides, and is believed by some to be especially useful in *rheumatic dysmenorrhœa*. In this affection, full doses of the ammoniated tincture should be given. The following formula, adapted from one of Professor Dewees, and known as *Dewees's Emmenagogue Mixture*, I rely upon almost exclusively in the treatment of simple atonic *amenorrhœa*. The proportion of the various ingredients should be varied to suit the exigencies of individual cases. Thus, the amount of iron should be altered according to the extent of the anæmia; of the aloes, according to the state of the bowels; of the cantharides, according to the susceptibility of the urinary organs:

R Tincturæ ferri chloridi, ℥iij; tincturæ cantharidis, fʒi; tincturæ aloës, fʒss; tincturæ guaiaci ammoniatæ, fʒiiss; syrupi, q. s. ad ℥vi.
S.—Tablespoonful three times a day.

TANACETUM, U.S.—The common tansy of the gardens, *Tanacetum vulgare*, in the form of decoction, or of its volatile oil, is sometimes used as a stimulant emmenagogue or for the purpose of producing abortion, but is a very unsafe remedy. When taken in sufficient amount it causes abdominal pain, vomiting, loss of consciousness, and violent epileptiform convulsions.* The minimum fatal dose of the oil of tansy which will cause death is not known, but in two cases (*Cincinnati Lancet and Clinic*, 1881) a teaspoonful of the oil produced violent epileptiform convulsions, and the same amount is said to have

* For references to fatal cases, most of which have occurred in the United States, see *U.S. Dispensatory*, also Professor Guillery (*loc. cit.*). Professor Guillery believes that the symptoms caused by the oil and by tansy tea are different. In a case of poisoning by the leaves, however, reported in the *Nashville Med. and Surg. Journ.*, 1879, xxii., the symptoms were those alleged to be characteristic of oil-poisoning; and the oil probably is the only active principle of the drug.

caused death (*U.S. Disp.*). Recovery is stated to have occurred after one and a half fluidrachms (*Lond. Med. Rec.*, 1882, p. 48); also after three fluidrachms (*Med. Bull.*, Philadelphia, 1888, x.). The action of the oil upon the lower animals has been studied by Professor Guillery (*Bull. Acad. Roy. Méd. de Bruxelles*, 1878, xii.). In frogs the most important effects which it was found to produce were paralysis of the peripheral endings of the motor nerves, with early appearance of post-mortem rigidity; and paralysis of the vaso-motor centre of the medulla, and of the inhibitory cardiac apparatus, with at last paralysis of the heart itself. In warm-blooded animals the oil produced symptoms precisely similar to those which it causes in man. After section of the spinal cord the convulsions did not occur in the hind legs: they are therefore of cerebral origin. The arterial pressure was not affected until death was at hand: so that it is evident that the drug has little action upon the heart.

OLEUM HEDROMÆ, U.S.—Under the name of *oil of pennyroyal*, in the United States, the oil of the *Hedeoma pulegioides* is used as a stimulating emmenagogue in domestic practice, but has very little power. Two fluidrachms taken by a young woman produced vertigo, faintness, muscular weakness, frequent feeble pulse, cold skin, and cold extremities (Dr. C. A. Bryce, *Southern Clinic*, vi. 323). Dose, from two to ten minims. In Europe the oil of *Mentha pulegium* is known as *oil of pennyroyal*.

FAMILY VIII.—OXYTOCICS.

Oxytocics are those remedies which are employed during or directly after parturition, to increase the uterine action. Of the few drugs which have claim for position in the present class, quinine has already been fully considered; it apparently differs entirely from the other known oxytocics in not producing continuous tetanic spasms of the uterus, and is therefore the safest stimulant to parturition at our command. The peculiar dangers which beset the use in labor of drugs which are able to cause uterine tetanus will be fully discussed in the article upon ergot.

ERGOTA—ERGOT. U.S.

Ergot is a blackish body, one to two inches in length, irregularly cylindrical, grooved along one side, and very generally curved, which is composed of very thick walled microscopic cells, containing oil-drops but no starch. Various opinions have been advanced in regard to the nature of this body; but as by the researches of Tulasne (*Ann. des Scien. Nat., Botanique*, 3e série, t. xx., 1853) it has been determined exactly what it is, I shall not occupy space with a discussion of the older views. Among the lowest of vegetable organisms, and distinguished from all other plants by the absence of chlorophyl, are the fungi. There are in most cases two distinct states or stages in the life of a fungus: in the first of these, the vegetable period, it exists as a *mycelium*, a usually filamentous mass or flocculus, whose sole function is to grow and increase; in the second stage the *thallus*, or ordinary fungus or mushroom, is formed, and to it is assigned the function of developing reproductive bodies, after whose maturing it perishes. Between these stages there is in some fungi an intermediate one, in which the plant exists as a *sclerotium*. The genus *Claviceps* comprises a number of parasitic fungi, which develop in the pistils of the various species of Gramineæ. The official ergot is the sclerotium of the *Claviceps* (*C. purpurea*, Tulasne) which infests the grain of *Secale cereale*, or rye. The first appearance of the fungus is during the earliest life of the pistil, at the base of which there arises a minute flocculent mass of mycelial filaments. These filaments, continually growing and invading all parts of the tissue of the pistil, at last form of it an irregular whitish body, at the base of which after a time appears a dark-colored body, the sclerotium, which continues to grow, lifting up the diseased and withering mass

formed out of the original pistil, and finally developing into a perfect ergot. If a fresh, living ergot be placed in a damp, warm place, after a time little cracks will appear in its surface, and through these cracks little round bodies will project, and finally be raised up on stalks and constitute perfect thalli,—minute fungi, which finally produce spores.

Ergot is an exceedingly complex substance, containing nearly thirty-five per cent. (Logrip) of an inert fixed oil, and, in minute amount, a peculiar ammoniacal base, which was stated by Winckler to be *propylamin*, but appears really to be *trimethylamin*. What its activity depends upon is unsettled, every chemist who has studied it arriving at a diverse result. Three alkaloids have been described from it,—two non-crystallizable, *Eboline* and *Ergotine*, by Winckler (*Amer. Journ. Pharm.*, May, 1864), and one crystallizable, *Ergotinine*, by Tanrot (*Bull. Thérap.*, xciii. 231); three acids, *Ergotic*, *Phosphoric* (Levi, *Lo Sperimentale*, Aug. 1875), and *Sclerotinic* (Dragendorff and Podwiansotzky, *Arch. für Exper. Path. und Pharmak.*, vi. 192); also various other substances of even still more doubtful nature.* It is very evident that, for all practical purposes, the chemistry of ergot is still chaotic, that we have no certain knowledge of what is the active principle of the drug, and that the watery extract (*Ergotin*, so called) may be used as the most condensed representative of the activities of the crude drug.

* Besides the papers quoted, the reader desirous of following up the subject should look at Houdelin (*Schmidt's Jahrb.*, Bd. clv.; T. C. Hermann (*Büchner's Repertorium f. Pharm.*, 1871. Bucheim (*Arch. f. Exper. Path. u. Pharm.*, Bd. iii.; also *Berl. Klin. Woch.*, 1876, p. 309. Sal-kowski (*Berl. Klin. Woch.*, 1876, p. 22); Zweifel (*Arch. f. Exper. Path. u. Pharm.*, Bd. iv., *Kobert's Arbeiten*, vii., 1892). Dr. Max Stumpf (*Deutsch. Arch. f. Klin. Med.*, xxiv. 417) asserts that in various hemorrhages he has obtained from the hypodermic use of sclerotinic acid most happy results, but Dr. Rennerb (*Centralbl. für Gynäkologie*, 1879) has met with nothing but failure. Dr. W. Nikitin (*Würzburger Phys. Med. Verhandl.*, xiii.) has studied the physiological action of the acid upon frogs, cats, and rabbits. I have seen the report only in abstract, but it is stated that the fatal dose for rabbits was fifteen grains, that directly after the injection the bodily temperature fell from 1° to 3°, and that there was a progressive lowering of muscular power and arterial pressure, and, finally, death from failure of respiration. The paralysis was found to be spinal, and when pregnancy existed contractions of the gravid womb were produced. On the other hand, a series of experiments at the laboratory of the University of Pennsylvania, made by Dr. Chas. M. Seltzer with imported sclerotinic acid, showed that this specimen at least did not at all represent ergot, and at present it does not seem probable that sclerotinic acid will prove of practical value. In an elaborate research (*De Bona Reymond's Archiv*, 1884, 434) upon the activities of the various derivatives from ergot, M. Marchwald found that the *ergotine* preparations (*Ergotinum Citricum* of Gehe, *Ergotinum Solutum* of Bonbelon) raise the arterial pressure, while *sclerotinic acid* depresses it, and *ergotin* (*aqueous extract*) first raises, then depresses, then raises it; also that the *ergotin* and *sclerotinic acid* act violently upon the uterus, while the *ergotine* preparations do not influence the organ. Dr. P. Kobert claims to have obtained from ergot two new acids and one alkaloid, the process for the preparation of which may be found in *Pharm. Centralhalle*, Dec. 25, 1884. *Ergotinic acid* is affirmed to be the principal constituent of sclerotinic acid and an important constituent of the original *ergotine* of Bonjenn. In full doses it is stated to act as a paralyzant to the spinal cord, but to be without influence upon the uterus. *Sphaclenic acid* is said to produce gangrene, while *cornutine*, the alkaloid, causes in dogs tetanic stiffness, passing into cramps and epileptiform convulsions. A. Grünfeld (*Kobert's Arbeiten*, viii., 1892) finds that pure sclerotinic acid given by the mouth possesses no poisonous properties, that sphaclenic acid is a powerful ergotizing poison when fresh, but becomes inert on keeping.

PHYSIOLOGICAL ACTION.—In ordinary therapeutic doses, ergot causes no immediate perceptible symptoms; but when a sufficient amount is exhibited, it acts as a poison both upon man and upon animals. Before considering its action when given in small quantity, I shall discuss its toxic effects.

According to Diez (quoted by Stillé), the principal effects of poisonous doses of ergot are in the lower animals profuse salivation, vomiting, dilatation of the pupils, hurried breathing, frequent pulse, cries, trembling, staggering, paraplegia, sometimes diarrhoea, sometimes constipation, prostration, urgent thirst, convulsions,* and death. Mr. S. A. Wright, in a series of experiments (*Edinb. Med. and Surg. Journ.*, Oct. 1839, vol. lii.), noted, when the medicine was given by the mouth, symptoms similar to those just spoken of: the paralysis was much more marked than were the spasms. Late in the poisoning, the heart's action became irregular and intermittent, and the pulsations, which had been rapid, grew slow and feeble. In some cases the special senses seemed to be destroyed, and coldness of the surface was a very prominent symptom. Mr. Wright also injected a strong infusion of the drug directly into the torrent of the circulation. Death was in some cases produced in nine minutes, the symptoms being immediate dilatation of the pupils, great increase in the rate of the cardiac pulsations, paralysis, and convulsions. When the fatal result was not brought about in so short a time, great anæsthesia of the surface was noted a considerable time before death; coldness of the surface and paralysis of the special senses were also present in some cases. In Dr. Kersch's experiments (*Betz's Memorabilien*, vol. xviii.†) the concentrated infusion was injected into the jugular vein; the coldness of the surface was especially noted, and also great muscular rigidity. Upon rabbits, according to the researches of Wright, ergot acts very feebly. In birds, as represented by chickens, turkeys, and pigeons, it causes symptoms analogous to those produced in mammals, as is testified to by Tessier and by Gross, both quoted by Stillé, and by Bonjean (*Traité de l'Ergot de Seigle*, Paris, 1845). Enormous doses of ergot are required to produce toxic symptoms in animals, since in one of Wright's experiments an amount equivalent to two drachms for every pound weight of the dog failed to kill.

Upon man the toxic influence of ergot is also very slight, and, although I have given the fluid extract in ounce doses, I have never seen it cause any distinct symptoms.‡ Fatal abortion has several times been

* Pereira (*Materia Medica*, 3d American edition, vol. ii. p. 137), on the authority of Phorbus, states that in the experiments of Diez convulsions were not present.

† Unfortunately, I have not had access to Kersch's paper, and know it only by abstracts in *The Medical Times of Canada*, vol. i., and *Schmidt's Jahrbücher*, Bd. clx. p. 120.

‡ For cases, see Neubert, *Journ. für Pharmacodynamik*, 1860, Bd. ii. p. 483, also, same case, Richter, *Cuspar's Vierteljahrsschrift*, Bd. xx. p. 177; Tardieu, *Ann. d'Hyg.*, 1855, vol. i.; *Toledo Med. and Surg. Journ.*, July, 1878.

produced by ergot; but I know of only two instances of decided poisoning in a non-pregnant person. In the first case (*U. S. Dispensatory*), gastric irritation, thirst, diarrhœa, burning pain in the feet, and convulsions are said to have preceded death. In the second case, Dr G. S. Oldright, *Canada Med. Journ.*, 1870, p. 404), two hours after taking the drug (amount not stated) there were developed tingling in the fingers and feet, cramps in the legs, arms, and chest, with dizziness and weakness; the pupils were dilated, the pulse was very small, and a feeling of coldness was complained of. These symptoms were relieved by the administration of stimulants and the use of external heat; after a time they recurred with greater violence; finally, under the reinstitution of the measures previously employed, the face became intensely congested and purplish red, pain in the head was felt, the patient seemed much excited,* and convulsions were feared, but did not occur; there was some diarrhœa, with dark-gray stools. In the case recorded by Neubert (*loc. cit.*), the great coldness of the surface was especially noted; and as this symptom was very prominent in the case recorded in the *Toledo Medical and Surgical Journal*, and has been so commonly remarked in ergotized animals, it probably is characteristic of poisoning by the drug. Dr. Davidson reports a case with fluid blood, jaundice, and universal hemorrhages, attributed with doubtful correctness to poisoning by ergot (*London Lancet*, 1882, ii. 526).

The above summary of the general symptoms caused by poisonous doses of ergot shows that the phenomena are mainly paralytic in their nature; but, although an enormous amount has been written about the drug, we have very little knowledge as to the immediate causes of the paralysis. Since both Wright (*loc. cit.*, pp. 320, 321) and Kohler have found that the voluntary muscles are not affected by ergot, it would seem that the nervous system must bear the brunt of the poison. Eugene Haudelin is said to have shown that the peripheral nerves are not affected,† and the experiments of Köhler have confirmed this so far as concerns the motor nerves and the watery extract of ergot. He found, however, that those portions of the drug not soluble in water appeared to increase the excitability of the peripheral efferent nerves, and that upon the peripheral sensory nerves both portions of the ergot acted as a feeble depressant. On the whole, it is probable that the chief action of the drug is upon the nerve-centres.‡

The chief interest to the therapist in regard to the physiological action of ergot centres upon its influence on the circulation, especially on the blood-vessels, and upon its action on the impregnated uterus. I

* These symptoms were very probably caused by the large quantities of alcohol taken.

† *Inaug. Dissert.*, Dorpat, 1871; abstracted in *Schmidt's Jahrbücher*, Bd. civ. p. 142.

‡ In 1884, T. Korkorin, in a St. Petersburg thesis, affirmed that pronounced and characteristic pathological alterations can be found in the spinal cord of animals slowly killed with ergot. The correctness of this, however, seems to be more than doubtful. See paper by A. Grünfeld, *Archiv f. Psych. u. Nerven.*, xxi., 1889-90.

shall discuss these points *seriatim*. Before doing so, it would be, perhaps, best to speak of the chronic poisoning by ergot; but, as any deductions from the symptoms of ergotism as to the physiological action of the drug would be at best only inferences, I shall defer the consideration of the subject to the section on toxicology.

Action on the circulation.—Although the heart is profoundly affected in acute poisoning by ergot, yet death is probably not due to this cause, since Wright (*loc. cit.*, p. 320) found that after death, even though the heart was quiet, it commenced to beat as soon as the congestion was relieved by an incision, and continued to pulsate for fifteen minutes.

One of the earliest careful cardiac studies of ergot is that of P. Eberty (abstracted, *Schmidt's Jahrbücher*, Bd. clviii. p. 127). He found that in the frog after the injection of a gramme of ergotin the heart suffers diastolic arrest and is unable to respond to stimuli. It is inconceivable that this can be due to other than a direct action of the drug upon the cardiac muscle; yet Eberty seems to believe it is caused by an influence exerted through the pneumogastrics, and it is said that after division of these nerves even very great quantities of ergotin are powerless to produce cardiac arrest.

In man, full doses of ergot unquestionably diminish the frequency of the pulse, since the phenomenon has been independently noted by Parola, Gibbon, Arnal, Hardy, Beatty (all quoted by Professor Stillé), and by Professors Bailly and Sée (*Bulletin Thérap.*, t. lxxviii. p. 435); but the method in which this reduction is brought about is uncertain. The amount of the reduction varies from ten to thirty-five beats per minute; but very rarely is the pulse reduced below sixty even by the largest doses. According to Eberty's experiments, therapeutic doses of the drug produce in mammals, as in man, slowing of the heart's beat. It was found that in frogs the pulsations of the heart were still affected after destruction of the medulla, but that in mammals, after paralysis of the peripheral vagi by atropine, ergot was powerless to alter the cardiac rhythm. These experiments, if correct, appear to prove that ergot acts as a stimulant to the peripheral cardiac nerves, and that the reduction of the number of beats is due to this, and is independent of the nerve-centres. Boreischa has noticed that toxic doses quicken the heart's action, and that under these circumstances galvanization of the par vagum has little or no effect upon the heart. It would seem, therefore, as if the drug first stimulated and then paralyzed the peripheral pneumogastrics.

As early as 1827, M. Courhant advanced the opinion that ergot produces a spasm of the blood-vessels; but, although his theory was very generally adopted, only within a very few years has any earnest attempt been made to prove or disprove its correctness. In 1870, Dr. Ch. L. Holmes (*Archives de Physiol.*, t. iii., 1870) found that when the blood-vessels of the frog's web were watched under the microscope and the animal poisoned either with the aqueous extract of ergot or with

the powdered drug, the vessels, both venous and arterial, could be seen to undergo a very great contraction. Dr. A. Wernich (*Virchow's Archiv*, 1872, Bd. lvi. p. 510) observed that when rabbits in which the arteries of the thigh, back, pia mater, etc., were exposed, received full doses of ergot, these arteries could be seen to undergo a very remarkable diminution in their calibre. These observations have been confirmed by other observers, among whom may be mentioned Vogt, Dr. S. Kersch (*loc. cit.*), Max Schüller (*Berliner Klin. Wochenschr.*, 1874, p. 305), and Boldt (*Schmidt's Jahrbücher*, March, 1872). The latter observer also affirms that there ran through the ergotized capillaries wave-like, peristaltic spasms. Patrick Nicol and J. Mossop (*Brit. and For. Medico-Chir. Rev.*, vol. i., 1872) have noted with the ophthalmoscope the contraction of the retinal vessels after the exhibition of ergot in man.

If general vaso-motor spasm be produced by ergot, unless the heart's action be greatly weakened by the drug there must be a very decided rise in the arterial pressure. Dr. Ch. L. Holmes (*loc. cit.*) first showed that when the aqueous extract is injected directly into the jugular vein of the dog, immediate, rapid, and very decided depression of the arterial pressure occurs, with violent cries and efforts on the part of the dog, followed by a period of quiet and a rise of the arterial pressure above the normal point. As Köhler and Eberty (*Virchow's Archiv*, Bd. lx. p. 384) and myself have all found that ergotin (Bonjean's) raises the arterial pressure enormously in frogs and mammals, the fact must be accepted as proved.

Dr. Holmes tried the effect of the injection of the ergot after section of the cardiac nerves, but obtained results so varying and contradictory that he could come to no other conclusion than that the alterations of the arterial pressure produced by ergot are not dependent upon its cardiac action. In the absence of details of these experiments, we can but accept this conclusion.

The unexpected result in the investigation of Dr. Holmes was the primary depression of the arterial pressure, a depression which at first sight seems incompatible with the idea that ergot contracts the vessels. It is, of course, possible that the fall of pressure may be due to an intense action of the drug upon the heart; but Dr. Holmes, in order to explain it, propounds a theory which is very plausible, but which he certainly does not prove to be true. His idea is that the first fall of the arterial pressure is due to a spasm of the pulmonic capillaries, hindering the blood in its passage to the left heart, and thereby causing venous repletion and arterial depletion. It is to be remembered that he injected the ergot directly into the jugular vein, so that the whole force of the remedy fell directly upon the pulmonic circulation. It is evident that this matters very little if ergot produces vaso-motor spasm only through an influence upon the nerve-centres, but that it does make a material difference if the contraction of the vessels be the result of a local action. Holmes asserts that after section of a sympathetic nerve

and injection of the ergot the vessels supplied by the divided nerve can be seen to contract, and Wernich confirms this observation. If ergot does thus cause vaso-motor spasm, it is plain that in Dr. Holmes's experiments this spasm must have been very intense in the lungs before the systemic capillaries were affected. Our investigator proved by experiment what *a priori* seems necessarily true, that if blood be prevented from passing freely to the lungs the arterial pressure falls very greatly. In this connection it is worthy of notice that the period of arterial depression following the injection of the drug into the jugular vein was very brief. In the only experiment detailed in full by Dr. Holmes, the pressure began to rise in three minutes after the completion of the injection; in five minutes it was nearly normal, and in eleven minutes it was above the normal point. If the asserted facts are all true, the theory of Dr. Holmes is plausible. It is, however, very doubtful whether the ergotic spasm is local in its origin. Evidence derived from judging by the eye as to whether a vessel does or does not contract must be taken *cum grano salis*, and the observations of Holmes, of Wernich, and of J. H. Peton (*De l'Action de l'Ergot*, Paris, 1878) are directly contradicted by the apparently careful and elaborate experiments of Dr. Paul Vogt (*Berlin. Klin. Wochenschr.*, 1869, No. xii.), in which the dilated vessels of the ear of a rabbit whose cervical ganglion had been extirpated could not be made to contract by ergot.*

The results obtained by P. Eberty (*Inaug. Dissert.*, Halle, 1873) are in accord with those of Vogt, and disagree with those of Dr. Holmes, especially in their bearing upon the question whether the contraction of the arteries is centric or peripheric in its origin. He finds that the arterial pressure rises directly and enormously after the injection of ergotin. This rise, which he acknowledges to be chiefly due to the contraction of the vessels, occurs in the veins as well as in the arteries, and in the frog as well as in the dog and the rabbit. According to his experiments, it must be, at least in the batrachian, centric, since in the frog it does not take place after destruction of the medulla. He also found that after the inhalation of nitrite of amyl the ergot caused rise of the arterial pressure. It is a fair inference that if the vaso-motor spasm be centric in the frog it is also so in the mammal.

* In a series of experiments made by Professor S. Ringer and Dr. H. Sainsbury (*Brit. Med. Journ.*, Jan. 1884) upon tortoises according to the method of Gaskell (see *Digitalis*, p. 357), the addition of ergotin greatly slowed the rate of flow through the arterioles.

These results certainly appear to be contrary to the previous drift of our evidence in showing that ergot acts locally upon the vessels. It was found, however, that the addition of ergotin to the saline solution used had no distinct effect until there was ten per cent. of the extract in solution. Ten per cent. of ergotin is enough very seriously to influence the viscosity of the saline solution, and it is probable that the slowing effect of the ergotin was the result of altered physical conditions,—a conclusion which is corroborated by the fact that the records clearly show complete loss of vitality in all parts of the tortoise experimented with, a loss of vitality which in all probability was shared by the arteries. Certainly these experiments cannot be accepted as valid in contradiction of the older results.

In an especial investigation of the subject (*Phila. Med. Times*, vol. iv.) I found that ergotin injected into a vein does, as Holmes states, produce in the mammal an immediate fall of the arterial pressure, which is shortly followed by an enormous rise. I also found that division of the cord, i.e., vaso-motor paralysis, does in dogs prevent the rise of the pressure. It must, therefore, be considered proved that *moderate doses of ergot cause a rise of the arterial pressure by stimulating the vaso-motor centre*; and that the first fall of pressure is due to a direct action on the cardiac muscle, upon which the ergotin is at once precipitated when thrown into the jugular vein, is demonstrated by the facts that the fall does not occur when the drug is introduced gradually into the circulation by hypodermic injection, and that the drug is a poison to the cardiac muscle, as was shown in my experiments as well as in those of Eberly.

In entire confirmation of this conclusion, Dr. John C. Hemmeter (*Medical News*, lviii., 1891) has experimentally found that injections of ergot produce contraction of the arterioles and capillaries in the omentum of a rabbit when the spinal cord is intact, but are unable to do so after destruction of the cord; also that the isolated frog's heart is greatly slowed and still more weakened in its beat by the local application of ergot; and that after destruction or section of the spinal cord ergot is powerless to raise the arterial pressure.

Haudelin is stated to have found that the arterial pressure falls after the exhibition of the poison. Brown-Séquard has insisted (*Archives de Physiologie*, 1870, t. iii. p. 434) that in ergotic poisoning there are two periods,—first, vaso-motor spasm, and secondly, vaso-motor paralysis; and Haudelin noted a fall of arterial pressure after toxic doses. Dr. Boroischa (*Arbeiten Pharm. Laborat. Moskau*, i. 55) also, in a number of experiments, using Bonjean's ergotin, found a very decided fall of pressure produced by the drug. In none of these experiments was there any rise of pressure at all; either the ergotin used was not equivalent to that employed by Holmes and myself, or else the result obtained was dependent upon the use of very large doses. In a series of experiments, Boroischa found that the fall of pressure after section of the spinal cord high up was proportionately not nearly so great as in the normal animal. This indicates that the fall of pressure was due to vaso-motor palsy. It would seem, therefore, that the conclusions of Brown-Séquard are correct, and that *decidedly toxic doses of ergot lower the arterial pressure, by depressing both the heart and the vaso-motor centres*.

Bodily Temperature.—The coldness of the surface, which has been so permanent in cases of ergotic poisoning, seems to depend upon a general fall of temperature. Hemmeter has noticed in numerous studies upon the lower animals that this fall of temperature commonly amounts to, and often exceeds, five degrees centigrade; he has also noticed a fall of temperature of two degrees Fahrenheit in the human being. The cause of the fall of temperature has not been made out. Hemmeter states that in several experiments he has found pronounced

reduction of urea elimination in dogs under the influence of ergot, and believes it possible, though not proved, that the fall of temperature is due to diminished general metabolism. It is possible that the slowing of the blood-current which is produced by ergot (as a necessary result of the increased resistance produced by the contraction of the blood-vessels, and which has been experimentally demonstrated by Hemmeter with Ludwig's stromuhr) has some connection with the fall of temperature.

Action on the Intestines.—The muscle fibres in the coats of the blood-vessels are certainly not the only non-striated muscles upon which ergot acts; indeed, the probabilities are strong that the drug influences muscular fibre of this character wherever it exists in the body. According to Wertheimer and Maguin (*Archiv d. Physiol.*, xxiv., 1892), ergot produces very active movements in the coats of the stomach, and Dr. Wright found very active intestinal peristalsis at the post-mortem examination of poisoned animals; further, both Dr. Wernich (*Virchow's Archiv*, 1872, Bd. lvi. p. 515) and Dr. Haudelin bear witness to the violent intestinal peristalsis produced in the lower animals by toxic doses of ergot.

Uterus.—Upon the uterus of parturient women ergot exerts a very pronounced and fixed influence, increasing the length and force of the pains, and, if it be given in sufficient dose, causing after a time violent tetanic cramp of the whole organ. The drug certainly acts in this respect upon the lower animals as it does upon man, since Youatt states that in a large experience, both with monogastric animals and with ruminants, he has never known the drug to fail in its action on the uterus of the parturient female.

The action of ergot in producing contraction in the impregnated but not parturient womb is by no means so constant. Upon animals, Dr. Wright found it to fail in all of a number of trials, as did also Bonjean in a single experiment. On the other hand, Dix (Stillé, *Therapeutics*, 2d ed., vol. ii. p. 585), Osler (*Ibid.*), and Percy and Laurent (*Ibid.*) found it to cause abortion in guinea-pigs, sows, rabbits, cows, and cats; and M. Bodin has reported an epidemic of abortion occurring among cows near Trois Croix, which he attributes to feeding upon ergotized grasses (*Journal des Connaissances Méd.*, 1842). The evidence of those who have used ergot for the induction of premature labor in woman tallies very closely with that which is brought forward in regard to the lower animals. As the matter is so settled, I shall not enter into an elaborate discussion of the effects of ergot upon pregnant women. To show that the fungus very often will act as an abortifacient, it is only necessary to quote Professor Ramsbotham, who states (*Obstetric Medicine*, Phila., 1860, p. 318) that he has made a "great number of trials," and found that "expulsive action soon followed its exhibition, with very few exceptions." It cannot be gainsaid, however, that very often the drug has failed: sometimes, no doubt, because of poor quality or because

given in insufficient dose, yet sufficiently often to show that its abortifacient action is uncertain.*

The question whether the uterine disturbance is of centric origin or is due to the direct action of the drug upon the uterus has now been answered with positiveness, although the answer, perhaps, cannot be considered final until corroborated. Some years since, Boreischa claimed that in several experiments he had succeeded in producing violent uterine movements with ergot after the division of all the nerve connections of the organ. This, of course, would indicate a peripheral action, but Dr. Wernich in two experiments found that no vermicular movements were produced in the unimpregnated womb by ergot after previous section of the spinal cord. In former editions of this work I have objected to these experiments as non-conclusive, on account of the feebleness of the animals used, but the very careful and elaborate research made by Dr. John C. Hemmeter seems to be conclusive. In repeated experiments, having found that the injection of ergotin produced contractions in the exposed uterus of a narcotized rabbit, he destroyed the spinal cord with a hot wire, and determined that ergot was no longer able to cause uterine contractions: that the failure of the ergot in these cases was not due to paralysis of the uterus by shock was then demonstrated by injecting ammonia into the veins, when violent uterine contractions occurred.

Summary.—Ergot can scarcely be considered to be a poison, but when taken in enormous amounts it is capable of producing vomiting, rapid breathing, weakness, growing paralysis, urgent thirst, peripheral and cerebral pains, dilated pupils, great feebleness of the circulation, convulsions, and death, the most characteristic symptom being the great fall of bodily temperature. The method by which these symptoms are produced has not yet been determined. Therapeutic doses of ergot increase blood-pressure by stimulating the vaso-motor centre in the medulla, but have no distinct influence upon the heart or the walls of the arterioles. Toxic doses depress the pressure by cardiac paralysis, and probably also by paralysis of the blood-vessel coats. Ergot so acts upon the centres in the lower spinal cord which preside over the uterine muscles as to produce violent uterine contractions, and finally uterine tetanus.

THERAPEUTICS.—As a therapeutic agent, ergot is employed both by the obstetrician and by the physician; and I shall consider these uses of it separately.

Owing to the power that ergot possesses of intensifying labor-pains, it has long been used in *uterine inertia* during parturition. Indeed, it was for this purpose that the drug was first employed in medicine, and thereby acquired the name of *pulvis parturiens*. The literature of the subject is immense, and all imaginable opinions as to the effects of the

* For a more elaborate setting forth of the matter, the reader may consult Professor Taylor's *Medical Jurisprudence*, 2d ed., 1873, vol. ii. p. 193.

drug when given in labor, and as to the advisability of its employment, have been advanced; but, without discussing these, I shall here simply point out the clearly-established rules for its use, and the clinically-determined dangers and advantages of its employment. If ergot be given in very small doses during labor, the natural pains are simply intensified; but if the dose be large enough to have a decided effect, their character is altered: they become not only more severe but much more prolonged than normal, and finally the intervals of relaxation appear to be completely abolished and the intermittent expulsive efforts are changed into one violent, continuous strain. It is evident that, if the resistance be sufficiently great, this may endanger the safety both of the mother and of the child. The dangers to the mother are twofold: there is a possibility of the uterus rupturing itself by its efforts; and, when the head comes down upon the perineum, if the soft parts be rigid there is a very strong probability that they will be lacerated. The danger of uterine rupture is, I think, a remote one; for although several alleged cases have been recorded, yet in very few is the accident clearly traceable to the asserted cause (see Stillé, *Therapeutics*, 2d ed., vol. ii. p. 591). The fatal character of the accident is such, however, that the possibility of its occurrence should always prevent the reckless use of the drug.*

The improper use of ergot is far more serious in its effects upon the child than upon the mother. During a violent uterine contraction, the passage of the blood from the placenta to the child must be interfered with, or, in other words, the respiration of the fœtus is temporarily

* The following conclusions are those of Professor Schatz (translated and condensed by Himmeter), as stated before the Third German Gynaecological Congress, at Fribourg, and seem worthy of being given here as the result of a very careful study by a thoroughly-instructed physician:

"I. The contractions of the uterus, when produced by ergot, in their manner and character do not differ from the normal. Ergot produces properly co-ordinated contractions of the uterus, provided large doses have not been given, and hence most probably acts by direct stimulation of the centre for uterine contraction.

"II. In case the contractions are already present, ergot increases their number but does not render them stronger. The intensity of the force of the contractions is influenced only in proportion to their frequency.

"III. As a general rule, in normal labor the force is greatest when the frequency of the contractions is from six to ten in thirty minutes. One should, in the employment of ergot, seek to maintain this frequency and not allow it to exceed ten contractions in thirty minutes.

"IV. The action of the æscle begins fifteen minutes after its administration by the mouth, and is greatest in thirty minutes. One can, therefore, judge of the effect of a dose of the drug only after the second half-hour after it has been given, and should under no circumstances administer it oftener than once in an hour, if one wishes to avoid the risk of producing too frequent and consequently too weak contractions by cumulative action, or of causing uterine tetanus.

"V. The effects of a dose last for one hour only, and the drug must therefore be repeated hourly. As a general rule, the proper dose to give is a very small one if uterine action has already begun. In order to be sure of availing too great a frequency of contraction with all its detrimental effects, it is necessary to begin with from eight to ten drops of the fluid extract, for instance, and to increase it with great care, repeating its use not sooner than one hour after the preceding dose."

stopped, so that its life depends upon the aëration of the blood during the intervals. If the latter be very much shortened, the life of the child is greatly imperilled; and if they be abolished, it must be destroyed, unless delivery occurs in a very few moments. These considerations are, I think, sufficient, without further discussion, to show the imperativeness of the rule *never* to give ergot in uterine inertia when there is much *resistance*, either in the bony or in the soft parts of the mother. In primiparæ such resistance is always to be looked for, and its degree often difficult to judge of beforehand; and in such women ergot should not be used at all for the purposes of expulsion. Even under the most favorable circumstances for its employment—when the woman has previously borne children, when the bony pelvis is capacious, and the soft parts are relaxed and dilatable—its use should be entered upon with caution; and if the accoucheur be skilful in the application of instruments, cases must be rare in which the latter are not preferable to the ecbotic.

In women of lax fibre, with roomy pelves, ergot may be used in uterine inertia if instruments are not at hand, or if they are objected to, or if the obstetrician is timid in their application.

At the close of parturition, ergot is very commonly employed to prevent *post-partum hemorrhage*; and in this case there is no objection to its use, and the remedy is invaluable. But, as it requires from fifteen to twenty minutes for its action when given by the mouth, ergot exhibited in this way cannot be relied upon to arrest flooding when it has already set in. To prevent the occurrence of the latter, it is an excellent rule to give a full dose of the ecbotic when the child's head is well down upon the perineum and beginning to emerge at the vulva. After labor, if a tendency to bleeding is manifested, ergot may be administered hypodermically.

For the induction of *premature labor*, ergot has been and still is to some extent used; but it is uncertain in its action, and offers no advantages over instrumental methods.

The success of ergot in arresting hemorrhage after labor soon led to its use in uterine hemorrhages in other than parturient or pregnant women; and the next step beyond this was its employment in other hemorrhages. In all forms of *hemorrhage* in which no direct local application can be made, ergot is to-day probably the most generally used remedy; and even when local applications can be made, ergot may often be exhibited internally as an adjuvant to the local styptic. It is thus employed in *menorrhagia*, in *hæmoptysis*, *hemorrhage* from the *gums*, *epistaxis*, etc. Ergot acts with especial rapidity and efficiency in these cases, if given hypodermically: used in this way, the suddenness of the result in hæmoptysis is sometimes surprising. Even when the hemorrhage is apparently dependent upon a dyscrasia, as in *purpura hæmorrhagica*, the hypodermic injection of ergotin may produce the happiest

results (cases, *Brit. Med. Journ.*, ii., 1874; *Phila. Med. Times*, vol. v.). The value of the drug in hemorrhage is no doubt dependent upon its power of contracting the small vessels. In colliquative night-sweats due to relaxation of the blood-vessels, ergot is a most efficient remedy.

Allied to its use in hemorrhage is the employment of ergot in *enlargement* of the *spleen* from various causes. Dr. Da Costa was the first to suggest hypodermic injections of the drug for this purpose, and he claims to have even cured *leukæmia* (*Amer. Journ. Med. Sci.*, Jan. 1875).

It was the supposed action of ergot upon the muscular fibres in the walls of the vessels that led Professor Langenbeck to try the effect of the hypodermic injection of the remedy in *aneurism*. The result obtained, as reported in the *Berlin. Klin. Wochenschr.* (vi., 1869), was surprising. How far surgeons have followed up this matter I do not know; but, according to Dr. Paul Vogt (*Berlin. Klin. Wochenschr.*, March, 1872), Schneider has cured a case of femoral aneurism, and Dutoit one of the subclavian. Vogt has himself employed the remedy successfully in a very severe case of *varicose veins* of the legs, of many years' standing. The remedy is injected into the immediate neighborhood of the aneurism or varix, one or two grains of the extract of ergot being employed every day. A good deal of local swelling and hardness is induced, and the good achieved has probably been simply the result of the local inflammation.

Very many years ago, Dr. F. B. Barlan-Fontayral proposed (*Journ. des Sci. méd.-pratiques de Montpellier*, tomes vi., vii.) the use of ergot in *chronic dysentery* and *diarrhæa*, on account of its power of causing contraction of the capillaries; and Massolaz, in an epidemic of chronic diarrhæa among the French troops serving in the East, found that the suggestion was well timed. Although Barlan-Fontayral afterwards published a book (*Le Seigle ergoté et de l'Application de l'Ergotine à la Cure de la Dysentérie et de la Diarrhée chroniques*, Montpellier, 1858) upon the subject, it attracted little or no attention. In 1871, Professor A. Luton, of Rheims (*Gaz. Hebdomad.*, Oct.), stated, as something new, that he had used ergot with remarkable success in a violent and protracted epidemic of *dysentery*. Successful cases of *chronic diarrhæa* are also reported by other observers (see *Schmidt's Jahrbücher*, Dec. 1871; *Lancet*, 1876, ii. 409): so that trials of the remedy should be made in all obstinate cases.

Another employment of ergot for the purpose of restraining excessive secretion is in *galactorrhæa*, in which affection it has been used with success by Dr. Le Gendre (*Bull. Thérap.*, t. lxxvii. p. 282), who was led to employ it by an observation of Drs. Poyet and Commarmond (*Annal. de la Soc. de Méd. de Saint-Etienne et de la Loire*, 1863) that wet-nurses fed upon ergotized bread lost their milk.

The action of ergot upon the blood-vessels suggests its employment in those cases in which there is local or general dilatation of the vessels. I have used it in *pulmonic congestion* with apparent good

results, and it has been highly lauded in the first stages of *pneumonia* by N. S. Davis (*Journ. Amer. Med. Assoc.*, 1884), by Sunol (*London Med. Rec.*, 1884), and later by other clinicians. It has been especially noted by Dr. J. E. Kelly (*Med. Register*, 1887), as giving immediate relief when injected hypodermically in low forms of *pulmonary hyperæmia*, such as occur in typhoid fevers. Ergot has also been recommended especially by O. Rosenbach, as a means of raising blood-pressure in cases of cardiac disease where there is thought to be not sufficient peripheral resistance; and Hemmeter believes that the diastolic pulse is due to a very low degree of pressure in the arterial system, and is an indication, especially in chronic cardiac disease, for the use of ergot. Rosenbach recommends the drug strongly in aortic insufficiency with cardiac dilatation. Ergot will probably also be found of service as a vaso-motor stimulant in *surgical shock*, and it has been used with asserted good results against *cerebral congestion* following injuries to the head. In case of *apoplexy*, by increasing the blood-pressure, its tendency is to do harm rather than good. It has also been especially commended in *congestion of the spinal cord* by Brown-Sequard, Hammond, Beard, and others, and I have myself used it with satisfaction. Dr. Hampel (*Practitioner*, vol. i. p. 263) recommends it in *whooping-cough*. Mr. Wonkes believes the pain of *neuralgia* (*Ibid.*, p. 257) to be due to congestion and serous effusion into the nerve-sheaths, and has used ergot with asserted good results. Dr. Daniel H. Kitchen (*Amer. Journ. of Insan.*, July, 1873) has employed it with great success in *headaches* of the most diverse and even opposite origins, and has cured (?) *epilepsy* with it. In the latter disease he continues its use for months. Hemmeter also claims that the consentaneous use of ergot increases greatly the efficiency of the bromides in epilepsy. Dr. Duhenne (*Munch. Med.*, xlv. 86) states that he has obtained most remarkable effects in the relief of *diabetes* by subcutaneous injections of ergotin. The general clinical experience, however, seems to be that whilst occasionally ergot does great good in diabetes, it usually fails to accomplish anything. When successful, it rapidly diminishes the glycosuria, thirst, and polyuria. In *diabetes insipidus*, though it often fails, ergot is perhaps the most generally useful remedy that we have. It is probable that both in true and false diabetes it does good when the primary lesion is congestion of the medulla oblongata.

In 1872 (*Berlin. Klin. Wochenschr.*, June 17), Professor Hildebrandt announced that in nine cases of *fibroid tumors* of the uterus he had used with the utmost advantage hypodermic injections of ergotin; and this practice has been followed very widely on this continent. It is scarcely to be doubted that cures are sometimes effected; but probably in the majority of cases* the drug simply lessens the uterine congestion, and

* See *Amer. Journ. Med. Sci.*, July, 1873; *Amer. Practitioner*, May, 1873, May, 1874, August, 1874; *Clinic*, April, 1873; *Lancet*, May, 1873; *Chicago Med. Journ.*, 1874; and especially Dr. Byford's Address, *Trans. Amer. Med. Assoc.*, 1875.

does good precisely as it does in *chronic subacute metritis* and in *subinvolution* and *hypertrophy* of the uterus (Meadows, *Practitioner*, vol. i. p. 166); it may be that sometimes it strangles the growth by causing uterine contractions. If the latter be the case, a cure, as is suggested by Professor Goodell (*Proceed. Med. Soc. of Pennsylvania*, 1873), is to be expected from the remedy only in mural and submucoid tumors.

An objection to the method of Hildebrandt is the great pain and local inflammation which often result; and Goodell proposes as a substitute the use of enemata or suppositories containing the drug.

Some years ago, led by a fancied resemblance between the physiological action of ergot and that of quinine, Dr. Duboué proposed the fungus as a succedaneum to the alkaloid in *malarial fevers*, and in support of his views he published a book entitled *Recherches sur les Propriétés thérapeutiques du Seigle ergoté*, Paris, 1873. He brought forward some evidence of the value of the remedy; but the latter has shared the fate of the older substitutes for the South American specific. Dr. Th. Clemons (*Deutsche Klinik*, 1865, p. 267) affirms that ergot affords the most potent relief in the *ammoniacal cystorrhœa* of paraplegics. He gives it internally, but especially uses injections into the bladder of a solution of ergotin (gr. ii to f3v). Ergotin suppositories are asserted to be of great value in *hemorrhoids* (*N. Y. Med. Record*, xvi. 563). I have used them in one or two cases without benefit.

Toxicology.—Enough has already been said in regard to the acute poisoning by ergot, except it be to state that, when abortion is threatened from its ingestion, in the maintenance of perfect quiet and in the free exhibition of opium are to be found all the measures of relief at our command.

Since the days of Galen, there have swept over larger or smaller districts of Europe epidemics of diseases which have been attributed to ergot. In many parts of Europe rye bread forms the great staple article of food of the lower classes. It always contains a small quantity of ergot, but not enough to have any deleterious effect upon the health. When the summer is wet and cold, the rye becomes very extensively ergotized, so that the fungus constitutes a large proportion of the materials entering into the bread. It is under these circumstances that there occur those epidemics of *ergotism* or chronic ergotic poisoning which have been recorded from time to time since the days of Galen and of Cæsar. It is not always the rye that causes these frightful losses of life, as Heusinger (*Journ. für Pharmakodyn.*, Bd. i. p. 405) has traced one epidemic to diseased oats. Before going further, it seems proper to state that Trousseau and Pidoux assert that these epidemics are not dependent upon any specific action of ergot, but are either epidemics of blood-diseases or simply the results of improper and insufficient food,—the outcomes of poverty, wretchedness, and famine. It seems to me indisputable that some of the various

epidemics which have been recorded were of this character, but certainly it is no less indisputable that others were not. Moreover, numerous scattered cases are on record in which a few persons or a family have been affected with ergotism unmistakably traceable to the use of bread largely composed of the fungus.*

The scope of the present work is such as to forbid my entering into an elaborate discussion of the epidemics of ergotism, especially as the subject has no practical bearing so far as the American profession is concerned, since the absence of deep poverty is so complete in our country that no one would feed on largely ergotized bread; and, in fact, no case of ergotism has as yet been recorded as occurring in the United States.†

There are two varieties of ergotism,—the spasmodic and the gangrenous.

Gangrenous ergotism has been especially observed in France, and is believed to be the same as the *Ignis Sacer* or the *Ignis Sancti Antonii* of the Middle Ages,—an affection which in 922 killed forty thousand persons in Southwestern France, and in 1128–29 fourteen thousand in Paris alone. It generally commences with itching and formications in the feet, severe pain in the back, contractions in the muscles, nausea, giddiness, apathy, with abortion in pregnant women, in suckling women drying of the milk, and in maidens amenorrhœa. After some time, deep, heavy, aching pains in the limbs, an intense feeling of coldness, with real coldness of the surface, profound apathy, and a sense of utter weariness, develop themselves. Then a dark-red spot appears on the nose or on one of the extremities; all sensation is lost in the affected part; the skin, perhaps over a large surface, assumes a livid red hue, and in the foci of local changes bullæ filled with serum appear. The adynamic symptoms, in severe cases, deepen as the gangrene spreads, until finally death puts an end to the scene. Very generally the appetite and digestion are preserved to the last, and not rarely there is an almost voracious hunger. The gangrene is generally dry, the parts withering and mummifying; but sometimes it is moist, and pyæmic symptoms may even be developed. Of course a very large number of cases do not terminate in death; but the part immediately affected is generally lost. In these cases the toes most generally are the portion destroyed, but it may be any one or all of the extremities; and the nose, lips, ears, and even the buttocks, sometimes bear the brunt of the disorder.

Spasmodic ergotism may in the lightest cases be manifested only by itching, formications, numbness, or complete anæsthesia of the fingers

* For an account of a modern epidemic, see *Deutsch. Arch. f. Klin. Med.*, xxiii. 248.

† Any one especially interested in the subject will find the literature very well represented in the references of Professor Stillé's work on Therapeutics, to which may be added Duboué's book, quoted on the previous page. For the reader of German, a very excellent résumé exists in Husemann's *Handbuch der Toxicologia*.

and toes or of the buttocks, and by gastro-intestinal irritation, as shown by colic, vomiting, diarrhoea, or constipation, and withal a ravenous hunger. In more severe cases these manifestations are intensified, and spasmodic symptoms appear, violent and painful tonic contractions affecting especially the flexors of the extremities, interrupted at times by intervals of quiet, but gradually growing into severe general tetanic paroxysms, with opisthotonos and emprosthotonos. In the intervals there are very generally muscular tremblings, and as the case progresses there are developed cerebral manifestations, such as disturbances of vision, photophobia, chromopsia, hemiopia, and periodic amblyopia and amaurosis, giddiness, cataleptic and epileptic paroxysms with or without loss of consciousness, delirium, and idiocy. Gastro-intestinal symptoms are always very marked, but with them is a characteristic ravenous hunger and a longing for sour food and drink. The skin is earthy or yellowish in its tint, and is often spotted with boils or pustules or semi-gangrenous vesicles. Death is apparently caused by exhaustion; and in those that recover, various local paralyses, habitual spasms, amaurosis, mental aberrations, or even idiocy, often remain through life. In a few cases the symptoms are still more violent, and the spinal and cerebral disturbances soon lead to death.

In some epidemics of ergotism the cases have been a mixture of the spasmodic and gangrenous forms of the disease.

The primary changes in ergotism are in the blood-vessels. Ergotic gangrene can readily be produced in the comb and tongue of chickens, and Professor v. Recklinghausen asserts the essential lesion in these cases to be hyaline thrombi in the arterioles and capillaries; whilst Grünfeld has found the walls of the vessels thickened, structurally changed, and their lumen occupied by thrombi, in some places full of blood-corpuscles, and in other parts undergoing hyaline degeneration (*Inaug. Diss.*, Dorpat, 1892).

ADMINISTRATION.—Ergot may be given in powder, but at present this method is very rarely used: the dose is half a drachm to two drachms. The U.S. Pharmacopœia recognizes a *wine* (*Vinum Ergotæ*, —15 per cent.), a *fluid extract* (*Extractum Ergotæ Fluidum*), and an *extract* (*Extractum Ergotæ*). The first of these is a good preparation for internal use, and may be administered, as an ecboic, in doses of half an ounce to two ounces. The fluid extract is, however, preferable. The usual ecboic dose is one to two drachms. In nervous diseases much larger doses are required: thus, in congestion of the spinal cord I usually begin with half an ounce, and increase it to an ounce three times a day.* The solid extract is given in doses of from five grains to

* It would appear that sometimes, owing to idiosyncrasies, even small amounts of ergot cause much disturbance. Thus, Dr. R. B. Faulkner reports (*New York Med. Journ.*, June 14, 1884) a case in which a fluidrachm of the fluid extract caused great sleepiness, swelling and redness of the feet, and violent prickling of the extremities, probably as the outcome of gastric irritation.

a drachm. Of the so-called *Ergotin* two varieties have been proposed, that of Bonjean and that of Wiggers. Bonjean's ergotin is made by exhausting the ergot with water, evaporating to the consistency of a syrup, precipitating the albumen, gum, etc., with an excess of alcohol, decanting the clear liquid, and evaporating to the consistency of a soft extract. This ergotin is believed to be about ten or eleven times as strong as ergot, five or six grains of it representing about a drachm of the drug.

The ergotin of Wiggers simply contains everything in the ergot which is insoluble in water. Köhler (*Virchow's Archiv*, Bd. lx.) has proved that Wiggers's preparation has no influence upon the circulation, but in toxic doses produces violent convulsions. It ought not to be employed therapeutically. Bonjean's ergotin is that usually kept in our pharmacies, and represents all the virtues of the remedy. The official *extract of ergot* (*Extractum Ergotæ*, U.S.) is as good for hypodermic use as Bonjean's ergotin, and in all respects represents the drug therapeutically. Its strength is five times that of the fluid extract; when used hypodermically five grains should be dissolved in five minims of glycerin, ten minims of boiled water, and half a minim of carbolic acid, and filtered: the danger of severe local trouble is also lessened by plunging the nozzle of the syringe deeply into the muscular tissues.

HYDRASTIS. U.S.

The rhizome and roots of *Hydrastis Canadensis*, an indigenous perennial, commonly known as *Golden Seal*. *Hydrastis* contains the alkaloid *berberine*, to which it owes its yellow color, and probably also two other alkaloids, *canadine** and *xanthopuccine*; besides its characteristic alkaloid, *hydrastine*. The latter occurs in brilliant four-sided prisms, inodorous and almost tasteless, but having a very bitter and somewhat acrid taste when in the form of a salt. Pure hydrastine and its salts can be obtained in the shops, but the *hydrastin* of commerce is an impure body containing berberine, hydrastine, and probably other more or less active alkaloids besides resin.

PHYSIOLOGICAL ACTION.—According to Falek and Guenste, toxic doses of *berberine* cause in dogs restlessness, convulsive tremblings, thirst, and diarrhoea, and finally partial paralysis of the hind legs. From seven to fifteen grains of it killed rabbits in from eight to forty hours. The symptoms were increased frequency of respiration and

* According to the experiments of Von Bunge, *canadine* in toxic doses produces a brief stage of psychical and motor excitability, followed by general paralysis and depression, with death from respiratory paralysis, and has little or no direct action upon the blood-pressure. The rate of pulsation in the isolated frog's heart is lessened, but the work done is not decreased by the moderate dose; larger doses paralyze the muscle of the heart. The voluntary muscles are not affected by the alkaloid, nor is the uterus, although diarrhoea with violent intestinal peristalsis is produced.

tremblings, followed by decrease of the rate of breathing, paresis, paralysis of the hind legs, great dyspnoea, and finally convulsions. Both Dr. Schurinow and Curci (see *Land. Med. Rec.*, Oct. 11, 1886) agree that berberine causes the arterial pressure to fall rapidly from vaso-motor paralysis,—Schurinow affirming, however, that late in the poisoning the peripheral vagus is paralyzed, in this being confirmed by Marfori (*Arch. f. Exper. Path. u. Pharm.*, xxvii.), although Curci asserts that the nerve is not at all affected. The heart's action is at first slowed and afterwards rendered more rapid, the muscular fibres, according to Curci, being finally paralyzed. The respiratory centres are depressed. Abdominal peristalsis is greatly increased. The urine, after toxic doses, becomes albuminous, and sometimes contains epithelial casts, while after death the kidneys are found inflamed (Curci). The action of the drug on the nervous system is feeble, but there is finally loss of voluntary power and of reflex activity, and also of sensation, the anesthesia being according to Curci of central origin, but according to Schurinow the result of paralysis of the sensory nerve-trunks. In man, as yet, no violent symptoms have been recorded as produced by berberine. Buchner took nearly twenty grains without causing anything more serious than a loose stool. As a bitter tonic it has been used by various physicians in doses of from two to five grains, and its action in this dose appears to be that of a simple bitter. It may be given in pill form or dissolved in alcohol.

The dominant alkaloid of *hydrastis* is *hydrastine*. In toxic doses it causes increased respiratory movements, followed after a time by lessened respiratory movements, salivation, vomiting, excessive peristalsis, muscular tremblings, weakness and rigidity, loss of voluntary movement, rise of bodily temperature (Bunge), (often followed by a fall), feeble, rapid pulse, clonic and tetanic convulsions, increased reflex activity, and death from cramp-asphyxia or general paralysis, or exhaustion with respiratory failure. (Bartholow, *Lloyd's Drugs and Medicines of North America*; Maya, *Therap. Gaz.*, 1880; E. Falek, *Virchow's Archiv*, Bd. cxix; Marfori, *Arch. f. Exper. Path. u. Pharm.*, 1890; Cerna, *Therap. Gaz.*, 1891; Serdzeff, *Inaug. Diss.*, Moscoow, 1890; Kuno von Bunge, *Inaug. Diss.*, Dorpat, 1893.)

The general physiological action of *hydrastine* and its salts is best studied system by system.

Nervous System.—We have no knowledge in regard to the action of *hydrastine* upon the cerebral hemispheres, and so far as I know there have been no cerebral symptoms recorded as produced by it in man. The convulsions which are so prominent in poisoning by it in the lower animals are accompanied by a heightening of reflex activity, and are certainly spinal, since they are not prevented by previous section of the cord, but are stopped by destruction of the cord. This period of motor stimulation is followed in the frog by loss of voluntary movement and depressed reflexes: at first the reflex power can be restored by section

of the cord (Cerna), and is therefore probably due to stimulation of Setschenow's centre; later it is irremediable. Cerna believes, but does not prove, that at this time there is centric motor palsy: it may be that this paralysis is really peripheral. In many cases the animal dies in a convulsion before the paralytic stage has been developed. Late in a protracted poisoning, and after death, the motor nerves are depressed or altogether paralyzed (Falek, Cerna), and Von Bunge has found that the local application of a solution of the alkaloid to a nerve kills it: it would therefore appear that hydrastine is a direct depressant to the motor nerve-trunks. Both Slavatinaki (quoted by Bunge) and Mays have noted lessening of the sensibility: Dr. Mays found in the frog that the anæsthesia is not prevented in a leg by tying the artery, although the alkaloid when brought in contact with a nerve-trunk paralyzes it. If in Mays's experiments the alkaloid did not reach by imbibition or other way the peripheral nerves, it must act upon both the sensory cord and the sensory nerves: Cerna affirms positively that any action it may have upon sensation is entirely subordinate to its effect upon motion, and Falek states that hydrastine placed in the eye causes no local anæsthesia. Upon the *muscles* the alkaloid has some influence, since both Falek and Bunge have found that its not too dilute solution directly applied to a muscle destroys its contractile power, a conclusion which is confirmed by Cerna, who further states that preceding the depression there is a stage of excitation in which the muscular contraction under stimuli is more complete and prolonged than normal.

Respiration.—When death takes place during a convulsion, it probably is due to cramp-asphyxia; but when it occurs during the paralytic stage, it is from paralytic asphyxia (probably, in part at least, of centric origin), the heart-beat continuing after death (Serdzeff).

Circulation.—It is affirmed by Dr. Cerna, as the result of numerous experiments, that hydrastine, whether in minute, medium, or toxic doses, and in whatever way administered, always, if in sufficient amount to impress the circulation, causes fall of the arterial pressure. This statement, however, is so contrary to the observations of Bartholow, of Fellner (*Wien. Med. Jahrb.*, 1885), of Falek (*Virchow's Archiv*, cxix, 1890), of Serdzeff (quoted by Bunge, page 47), of Marfori, and of Pellacani, that there must be some error in the statement. According to the great bulk of authorities, when injected into the vein of an animal hydrastine produces an immediate fall of pressure, followed by a marked rise, which continues for a length of time, unless, indeed, the original dose has been very large, when the pressure falls progressively until death. The first or primary fall of pressure appears to be wanting after subcutaneous injection (Falek), and is probably due to the direct action of the concentrated drug upon the heart. According to Fellner, the rise of arterial pressure is not prevented by previous section of the splanchnic nerve or of the spinal cord high up: if these

observations be correct, the rise must be due, at least in part, either to heart stimulation or to action upon the vessels themselves.

It is probable that the muscle-fibres throughout the body share in the stimulating influence of hydrastine, and that the increase of arterial pressure is caused by, first, direct stimulation of the heart-muscle; second, contraction of the muscle-fibres in the smaller blood-vessels. In corroboration of the first of these conclusions we have the remarkably high and full pulse-waves noted by various experimenters, as well as the statement of Serdzeff, that he has proved an actual increase in the working power of the heart, and the observation of Marfori, that the slow, powerful cardiac beat is caused by hydrastine in the isolated heart of the frog. In confirmation of the second conclusion,—namely, that the vessels are contracted,—Marfori found, in experiments made with Roy's oncometer upon the dog's kidney, a constant contraction of the organ. It may be, as Marfori believes, that the vaso-motor centres are also stimulated, but at present this can only be considered a probability. All experimenters agree that after a toxic dose of hydrastine the arterial pressure falls, and that the fall of pressure is in part produced by a direct depression of the heart-muscle or its contained ganglia; a depression which ends in diastolic arrest with loss of muscular irritability. It seems also almost certain that at this period there is a widening out of the blood-paths, due to a direct paralysis of the muscular fibres of the arterioles in vessels, and also of the vaso-motor centres. The characteristic slow pulse produced by the moderate dose of hydrastine, according to Cerna, occurs after section of the pneumogastric nerve, and must therefore be the result of a direct action upon the heart-muscle or its contained ganglia. Cerna states that the vagi nerves retain their power to the end of the poisoning.

Abdominal Action.—It is probable that hydrastine influences both the glands and muscular fibres of the alimentary canal. According to Cerna, it markedly increases the secretion of saliva and of bile, also the intestinal peristalsis.

Uterus.—As long ago as 1883, Professor Schatz called attention to the practical value of hydrastis in all forms of hemorrhage from the womb, claiming that though the drug acts well in cases of uterine fibroids or myoma it is also efficacious in various cases of menorrhagia, dysmenorrhœa, etc. These results have been confirmed by numerous gynecologists. It is, of course, not possible from these clinical results to determine whether the good is obtained by an action of the drug upon the uterine mucous membrane or blood-vessels, or by provoking contractions of the uterine walls. As the result, however, of experiments upon the lower animals, both Fellner and Slavatinski affirm that hydrastine has a distinct ecbotic action, causing uterine contractions in the non-pregnant uterus and abortion in pregnant rabbits. Dr. Slavatinski reports a case of premature labor produced by hypodermic injections of two to three grammes repeated daily. It would seem,

therefore, that hydrastine is an ecboic, and that it arrests uterine hemorrhage in part, if not altogether, by provoking muscular contractions.

Eyes.—Hydrastine locally applied to the eye causes at first contraction and afterwards dilatation of the pupil (Cerna).

Absorption and Elimination.—Hydrastine appears to be absorbed from the alimentary canal somewhat slowly; at least, it is stated by Bunge that ten times as much of it is required to kill an animal when given by the mouth as when injected hypodermically. Marfori states that it is apt to have a cumulative action when given for a length of time. It escapes unchanged through the kidney, and has also been found by Hirschhausen in the feces.

Summary.—By primarily stimulating the spinal motor cord hydrastine causes tetanic convulsions with heightened reflexes, followed, if the dose have been large enough, by loss of reflex activity, and motor paralysis, which are probably in part due to depression of the motor centres, and are certainly, at least in part, the outcome of depression of the motor nerves and also of the muscles themselves. According to Cerna, the first loss of reflex activity is due to stimulation of Setschewnow's centre, and the final muscular depression is preceded by excitation of the muscle-fibres. Death may occur in a convulsion from cramp, asphyxia, or later from simultaneous paralysis of the respiratory centres and of the peripheral apparatus. The arterial pressure is first altered and secondarily depressed: the first rise of pressure is probably due to the stimulation of the heart-muscles, increasing the output of force, and of both the vaso-motor centres and the muscle-fibres in the arteriole coats, causing contraction of the blood-vessels: the fall of pressure is the result of a direct paralytic action exerted upon the muscle-fibres in the heart and in the arterioles. Hydrastine notably increases intestinal peristalsis, and probably uterine contractions. It would seem to be a universal muscle-poison, which acts upon both striated and non-striated muscle-fibre in heart, arterioles, intestines, uterus, and generally throughout the body; its first stimulant action being followed by marked depression.

THERAPEUTICS.—When locally applied, the preparations of hydrastine have a very remarkable effect upon the mucous membranes. They have been used with asserted excellent results in *chronic gastro-intestinal catarrhs*, especially those due to alcoholic excesses: as Professor Rutherford (*Brit. Med. Journ.*, 1879, vols. i., ii.) found in his experiments upon the lower animals that the hydrastin of commerce caused a marked increase in the biliary secretion, it is probable that in these catarrhs spoken of the good result is, at least in part, due to a specific influence upon the liver and probably other abdominal glands. Nevertheless, it would seem certain that hydrastin has a peculiar action upon mucous membranes. In the second stages of *gonorrhoea*, after the acute inflammation has been subdued, injections of hydrastin, or the fluid extract,

suspended in mucilage, are often of service. Five grains of the commercial impure hydrastin, or ten to twenty minims of the fluid extract, may be used to the ounce of fluid. It is also claimed by various specialists that in *otorrhœa*, *nasal*, *vaginal*, and other *mucous catarrhs* the remedy is locally of great value. In *dyspepsia* it has been used as a stomachic stimulant, and has received especial praise in the *vomiting of pregnancy*. At present it is not known to which of the various ingredients of commercial hydrastin these local effects are chiefly due, so that either the hydrastin or a preparation of hydrastis is preferable to the pure alkaloid. These preparations are a *tincture* (*Tinctura Hydrastis*—20 per cent., U.S.), the dose of which is from one-half to one fluidrachm; a *fluid extract* (*Extractum Hydrastis Fluidum*, U.S.), dose from one-half to one fluidrachm; and a *glycerite* (*Glyceritum Hydrastis*, U.S.), dose from one-half to one fluidrachm. The dose of commercial hydrastin is five to ten grains. For internal or general medication, as contrasted with the local use of hydrastis, the alkaloid or its salts is much preferable to the cruder preparation. As anti-hemorrhagic or eccholic, a salt of *hydrastine* may be used in doses of one-sixth to one-half grain. Whenever a speedy action is required, it should be given hypodermically.

HYDRASTININÆ HYDROCHLORAS—HYDRASTININÆ HYDROCHLORATE. U.S.

Hydrastinine is an artificial alkaloid first produced by Martin Freund by the oxidation of hydrastine. The hydrochlorate is a light-yellow crystalline powder, somewhat deliquescent, odorless, having a bitter saline taste, soluble in 0.3 part of water and in three parts of alcohol.

PHYSIOLOGICAL ACTION.—For our knowledge of the physiological action of hydrastinine we are chiefly indebted to Pius Marfori, P. J. Archangelsky, and Kuno von Bunge (*Inaug. Diss.*, Dorpat, 1893). No cases of poisoning by the remedy in man have been reported, but in frogs the alkaloid is said to produce complete paralysis with death from failure of respiration, the heart being finally arrested in systole; whilst in mammals it causes hyperæsthesia, general tremors, rapid pulse, and dyspnoea, followed by paresis, which is said primarily to affect the front legs and to pass into general paralysis with dilated pupils, lowered temperature, and death from failure of respiration. According to Von Bunge, intestinal peristalsis is markedly increased by hydrastinine. The methods in which the alkaloid causes these symptoms are best studied system by system.

Nervous System.—Our present knowledge of the action of hydrastinine upon the cerebrum is derived from experiments upon the lower animals, in which it has been found by Dr. W. Kiselew (*Schmidt's Jahrb.*, Bd. cxxxviii.) that the excitability of the motor cerebral cortex progressively decreases with progressively increasing doses of hydrastinine,

although it never entirely disappears; and that the white substance of the brain is affected similarly to but less powerfully than the gray matter. Kiselew has also confirmed the previous observation of Professor Tarchanoff, that the alkaloid arrests or greatly diminishes the convulsive attacks in epileptic guinea-pigs. It is further worthy of remark that Kiselew, in a few cases of human *epilepsy*, obtained very favorable results from the administration of 0.01 to 0.03 Gm. of hydrastinine four times a day.

So far as the lower motor apparatus is concerned, the chief symptoms produced by hydrastinine are paralysis with loss of reflex activity, and also lessening of the general sensibility. It seems at present doubtful whether there is or is not an early stage of nervous excitement, since Archangelsky affirms that there is increase of susceptibility to touch and to pain in the frog after small doses, whilst Marfori states that there is no increase at any time of the reflexes. If there be in truth any stage of excitement, it cannot be well pronounced. It is affirmed that hydrastinine is the natural antagonist of strychnine, and Marfori claims that the paralysis is of purely central origin. This, however, seems to be incorrect, for not only, as Archangelsky found, is the excitability of the voluntary muscle lessened by the toxic dose of the alkaloid, but Von Bunge has shown that both the peripheral nerves and the muscle-fibres were paralyzed by a local application of the hydrastinine solution.

In the advanced poisoning the respiratory centre seems to show the depressing influence of the alkaloid, and hence respiratory failure; but here again, according to Archangelsky, especially when the dose has not been too large, there is a period of primary centric stimulation.

Circulation.—The elaborate studies of Von Bunge show that hydrastinine has no influence upon the blood itself, but all observers are in accord in stating that the blood-pressure is increased by the large dose of the alkaloid. The increase appears to be in part of cardiac and in part of vascular origin. Thus, both Marfori and Von Bunge, in experiments made in the Williams apparatus, found that the systolic impulse of the isolated frog's heart becomes abnormally strong under the influence of the drug, and that the amount of the heart's work is distinctly increased. A second cause of the rise of the arterial pressure is asserted to be contraction of the vessels, which, according to Marfori, may become so great as to entirely arrest the renal secretion. As the result of elaborate experiments made with section of splanchnic and of the spinal cord, Archangelsky reaches the conclusion that the contraction of the vessels is chiefly of peripheral origin,* although there is at the same time some stimulation of the vaso-motor centres in the medulla.

* The assertion of Von Bunge, that because in heavily chloralized animals hydrastinine fails to elevate the pressure, therefore it acts chiefly upon the vaso-motor centre, is a non sequitur, as chloral acts upon the whole circulatory apparatus. Moreover, Von Bunge's own experiments show that the alkaloid lessens the size of the spleen by contracting the blood-vessels.

a conclusion concurring with Marfori's results. When the amount of the hydrastinine has not been too large, the elevated arterial pressure gradually returns to the norm (Von Bunge); but after a fatal dose of the alkaloid a pronounced fall of pressure finally comes on, apparently as the result of the paralysis of progressive asphyxia, since artificial respiration will bring back the pressure to the norm (Marfori): further, it is asserted by various observers that the heart is finally arrested in systole, so that it would seem that hydrastinine differs from hydrastine in not being a cardiac paralyzant in any dose.

Pupils.—Archangelsky has noted that one to two drops of the ten-per-cent. solution of a salt of hydrastinine in the eye will produce a dilatation of the pupil, which reaches its maximum in two to three hours, and remains twelve to fifteen hours.

Uterus.—The effect of hydrastinine upon the uterus was studied in pregnant and puerperal dogs, cats, and rats by Archangelsky, who found it produced, independent of any vaso-motor influences, apparently by stimulation of the uterine walls, rhythmic contractions. On the other hand, Von Bunge, having failed in two experiments to provoke abortion or uterine contractions in pregnant animals by large or even fatal doses of the alkaloid, claims that it is not an ecboic. Nevertheless, Dr. Faber (*Therap. Monatsch.*, vii., 1892), as the result of a number of trials, states that hydrastinine given hypodermically during human labor very notably increases the force and length of the uterine contractions, causing a spasm which affects all portions of the uterus, and which is similar in character to that provoked by ergot. In some of the cases there was uterine tetanus, lasting as long as fifteen minutes. Dr. Faber also asserts that distinct contractions can be produced in the unimpregnated womb.

Absorption.—Von Bunge has found that hydrastinine is readily absorbed and eliminated unchanged, chiefly with the urine, but also to some extent with the saliva, bile, and intestinal secretions. It did not appear to increase the amount of bile secreted.

Summary.—Hydrastinine in sufficient dose appears to be a powerful depressant to the whole motor tract, commencing in the motor area of the cerebral cortex and ending in the muscle, motor brain, motor cord, motor nerve, and muscle being all more or less affected. Whether this depression be or be not everywhere preceded by a brief stage of excitement is at present uncertain, but it is extremely probable that there is a primary stimulation, at least, of the muscles. It is a stimulant to the circulation; the heart under its influence acts more slowly, but more powerfully, and is in fatal poisoning finally arrested in systole, whilst the blood-vessels undergo powerful contractions until late in the poisoning; the vascular contractions are probably the result of stimulation of the vaso-motor centre and of the muscle in the walls of the arterioles. The final fall of arterial pressure is asserted to be the result of the asphyxia, and not produced directly by the drug. Although it is denied by some,

hydrastinine appears to be a powerful oxytocic, and it is probable that its action upon the heart, the arterioles, the uterus, the intestines, and the skeletal muscles is the outcome of a wide-spread general muscular stimulation.

THERAPEUTICS.—Hydrastinine has been used in medicine with growing favor, chiefly for those complaints for which it was originally recommended by Falek,—namely, *menorrhagia*, *metrorrhagia*, *congestive dysmenorrhœa*, and even *endometritis*. The testimony in favor of its arresting uterine hemorrhage in all forms is on the whole very consistent, and is abundant, but it is also believed by many gynecologists to have some alterative influence upon the mucous membrane of the uterus. It is claimed for it by some gynecologists, but denied by others, that it is an active oxytocic, and exerts its influence upon impregnated and unimpregnated wombs largely by causing muscular contractions. It will be seen that the range of its usefulness in gynecology is entirely similar to that of hydrastine; it has, however, acquired popular favor more rapidly and decidedly than the natural alkaloid. It may possibly be more effective, but its superiority probably lies in chief part in its being distinctly less toxic and producing no cardiac depression. When an immediate impression is desired, the sulphate should be given hypodermically. When a prolonged continuous action is desired, it may be administered by the mouth. The results obtained by Kiselew demand a fair trial of it in *epilepsy*, and it has also been recommended as a *cardiac tonic*, a recommendation which is emphasized by my own recent and not wide experience. The dose is from three-quarters of a grain to a grain and a half.

GOSSEYII RADICIS CORTEX, U.S.—The root of the ordinary cotton-plant, the *Gossypium herbaceum*, is asserted to be used by the negroes in various portions of the South as an *abortifacient*, and Dr. Bouchella, as long ago as 1841, claimed for it medical properties similar to those of ergot. It has not, however, come into general use, and our knowledge of its properties is at present very scanty and uncertain. In the experiments of Dr. I. C. Martin enormous doses produced heaviness and stupor in both frogs and mammals, but did not cause abortion in pregnant guinea-pigs and rabbits: neither the spinal cord, the muscles, nor the nerves were affected (*Amer. Journ. Med. Sci.*, Jan. 1882); but Dr. H. I. Garrigue has found it a most serviceable agent in arresting hemorrhage and ameliorating the other symptoms in *uterine polypoid* and *fibroid tumors*, and even in *uterine cancer*. He insists that the commercial fluid extract is inert and the decoction must be freshly prepared (*Quart. Bull. Clin. Soc.*, New York, Jan. 1887). The oxytocic dose of a decoction (℥iv in a quart of water boiled to a pint) is stated to be a wineglassful, to be repeated every thirty minutes as necessary. The remedy has also been employed in *amenorrhœa* and in *dysmenorrhœa*, in which diseases from three to five grains of a solid aqueous extract

have been given three times a day. The *fluid extract* (*Extractum Gossypii Radicis Fluidum*, U.S.) may be used in doses of a fluidrachm.

The *Smut of Indian Corn* (*Ustilago*) appears to have active medicinal properties, and should be investigated. It has been used with alleged success in *uterine inertia* during labor by Dujardin-Beaumetz (*Bull. Thérap.*, xciii. 85). Dr. James Mitchell has found that in the frog the *ustilago maidis* abolishes sensation and reflex action before voluntary motion; he states that reflex action is destroyed at a time when motor nerves and muscles are still active, and that consequently the first influence of the poison is upon the sensory side of the lower nervous system; late in the poisoning the whole motor tract became involved (*Therap. Gaz.*, ii. 223). It has been employed in the Philadelphia Hospital during labor by Dr. W. A. N. Dorland, who has found that in doses of one to two drachms of the fluid extract it has a very marked influence upon the uterine pains, increasing them in severity, frequency, and duration. He claims for it that it will not produce a prolonged tonic contraction as does ergot. This is, however, doubtful. (Consult also *N. Y. Med. Journ.*, xxiv. 654; *Schmidt's Jahrbücher*, Bd. clxxii. p. 19; *Centralbl. für Med. Wissench.*, 1876, p. 228; *Chicago Med. Times*, 1879-80, xi. 434).

FAMILY IX.—SIALAGOGUES.

SIALAGOGUES are medicines which increase the flow of saliva and of the buccal mucus. Various substances, such as mercury, when taken internally, affect the mouth and its tributary glands in such a way as to produce salivation: these substances are, however, never employed in medicine for this purpose, so that practically sialagogues are local remedies acting by the induction of a local impression on the mouth. The influence which they exert is a stimulant one, and most of them are more or less irritant. They are used to effect two distinct purposes. Some of them dissolved in the saliva pass over and directly stimulate the mucous membranes not only of the mouth but also of the fauces and of the epiglottis. Other sialagogues, by exciting a very great flow of saliva, seem to lessen the congestion of the part.

In reference to the first of these modes of action, sialagogues are employed in relaxed conditions of the mucous membrane of the fauces, and even of the larynx. Chief among the substances so used is *cubeba*, which when slowly chewed in the mouth exerts a very decided local influence, and is useful in relaxation of the fauces, of the uvula, and even of the upper portions of the larynx. Either in the form of the berries or made into lozenges, cubeba is much used by public speakers; and in the *hoarseness* from relaxation following over-use or slight inflammation, it is often very efficient. Through their depletory influence, sialagogues are sometimes useful in allaying *rheumatic toothache*, or other rheumatic irritations about the jaws.

PYRETHRUM, U.S., or Pellitory, is the product of *Anacyclus Pyrethrum*, a small herbaceous perennial, growing in the neighborhood of the Mediterranean. It is a small root, about the size of the little finger, wrinkled longitudinally, light brown externally, with bright, shining spots on the surface, hard, brittle, with a resinoid radiated fracture. It is inodorous, and when chewed is at first almost tasteless, but soon becomes acidulous, saline, and acrid, and produces a very persistent burning, tingling sensation, which is accompanied by a profuse flow of saliva. Half a drachm to one drachm of it may be chewed at a time in painful *rheumatic affections of the face*, in *toothache*, in *relaxation of the uvula*, and in similar disorders. Taken internally in excess, it acts as a narcotic irritant, fifty minims of its tincture having caused gastro-intestinal irritation, with violent convulsions, which nearly proved fatal, in a child three and a half years old (*Practitioner*, xvii. 86). The only official preparation is the *tincture (Tinctura Pyrethri)*, which is never used internally.

FAMILY X.—ERRHINES.

THESE are substances employed to act upon the mucous membrane of the nose. Strictly speaking, the term should be applied only to those drugs which are used to excite secretion in the nasal mucous membrane. Such remedies are, however, so rarely used as to be by themselves scarcely worthy of notice. The employment of irritating vapors to arouse the nerve-centres by stimulating the nerves distributed in the nasal mucous membrane is a very old and a very popular custom. *Smelling-salts*, or preparations of hartshorn, so much used by ladies as a slight stimulant, and by others in reviving those who are suffering from or threatened with fainting, act in this manner. The ammonia held close to the nostrils brings about the reaction, not by any direct stimulating action on the circulation, but by irritating the nasal mucous membrane, as is proved by the rapidity of its influence and by the exceedingly minute quantity which will sometimes act efficiently. In the use of hartshorn, especially with young children, it is necessary to exercise care, lest injury be done to the delicate mucous membrane. The only errhine used for the purpose of influencing affections of the nasal passages themselves which is worthy of mention here is *cubeba*. This freely snuffed up in powder is very useful in *acute coryza*, after the first stage of congestion and dryness has passed away.

FAMILY XI.—EPISPASTICS.

Counter-irritation.—Almost from time immemorial, physicians have believed that morbid processes in deep-seated or superficial organs could be modified by irritations artificially induced in distant parts. To the drugs used for producing these remedial irritations the name of revulsives, or counter-irritants, has been given, the process being called revulsion, or counter-irritation. Latterly, the value of these remedies in disease has been questioned, chiefly because not only were the accepted theories of their action deemed untrue, but also any explanation of how they do what is claimed for them was asserted to be, in the present state of our knowledge, inconceivable.

Evidently, in studying the matter, the inquiry should be divided into two parts, and fact should be separated from theory; the effort being made to ascertain, first, whether experience does or does not demonstrate that it is possible by an irritation to affect a distant part which has no apparent connection with the seat of the new irritation; secondly, whether the facts taught by experience are in truth irreconcilable with reason. In regard to the first part of this inquiry, it seems to me indisputable that experience does teach, in the most unequivocal manner, that an organ may be affected through a distant part. There are physiological proofs of this, which it is only necessary to allude to: such is the relation of the uterus and the mammary glands. The proofs which may be drawn from disease are, however, much more numerous and striking. Thus, it is well known that in mumps there may be relief of an existing irritation of the salivary gland by a new irritation of the testes; in gout, the swelling of the toe will relieve the disordered digestion, etc. If it be affirmed that these phenomena, happening during the existence of a blood-disease, are *sui generis*, the objection cannot be made to the paraplegia produced by the irritation of a calculus in the kidney, or to the headache due to the irritation of the gastric mucous membrane by acid, or to the shoulder-pain of diseased liver, or to the amaurosis caused by the irritation of a decayed tooth. A well-known experiment of Brown-Séquard's illustrates the point so well that it may be quoted. In it he found that if one sciatic nerve of a guinea-pig be cut, epileptic attacks may be produced by gently rubbing the back of the ear upon the same side. A very curious instance of an external irritation affecting a deep-seated part is the duodenal ulcer produced by burns, especially of the abdomen. The pathological evi-

dence of the truth of the present proposition is simply overwhelming, and facts might be brought forward almost indefinitely to show that irritations are capable of affecting the functions and nutrition of distant parts. This being true, surely it is in the highest degree reasonable to suppose that artificial irritations can in a greater or less measure be controlled so as to affect the distant organ for good and not for evil.

Clinical experience has certainly demonstrated that this can be done. The value of any individual counter-irritant in this or that disease is not the present question; but certainly no physician who has had any practice can have failed to see instances of relief from the use of counter-irritants. A case of obscure brain-trouble recalls itself at present writing, in which stupor and a clear intellect alternated at will, according as the drastic cathartic was given or withheld. The relief of abdominal pain, or "stomach-ache," by a mustard plaster, is a daily nursery experience.

From what has been already stated, it may be laid down as proved beyond cavil—first, that we have power to influence internal morbid processes by creating external irritations; secondly, that the fact of counter-irritation exists, whether we can or cannot explain its rationale.

Physiological knowledge is not yet sufficiently extensive to enable us to perfect a theory of counter-irritation. The action of these remedies is complex, but I think can be explained at least in part. There is only a certain amount of blood in the body. If it be accumulated in one place, it cannot be in another. Thus, the difficulty of studying after a hearty dinner probably depends, as do the cold feet so common in feeble persons under such circumstances, upon the accumulation of blood, and probably also of nervous energy, in the digestive organs. Now, by artificial interference, by determined study, by violent exercise, we can often draw the blood away from the alimentary apparatus into the cerebrum, or into the motor system, and produce indigestion. Clinical experience proves that we can also reverse this process. The brain is excited, the blood is concentrated in it, congestion exists, inflammation is threatened; a drastic cathartic is given, the blood is drawn into the intestinal canal, and by revulsion the brain is relieved. Certainly this is not mysterious, not inexplicable. All forms of counter-irritation cannot, however, be explained on the above principle. It is a probable, but not a positive, teaching of modern physiology that there are nerves which preside over nutrition,—the so-called trophic nerves. If this be so, it is to be expected, *a priori*, that peripheral irritations will cause reflex alterations of nutrition, precisely as they cause reflex disturbances of the motor functions. Further, whether these trophic nerves do or do not exist, there are vaso-motor nerves, and the duodenal ulcer of burns is a positive proof that, either through the trophic or through the vaso-motor nerves, external irritations do produce internal reflex alterations of nutrition. The sympathetic ophthalmia caused by a morbid eye in its healthy fellow, or induced by a

diseased tooth, is another instance of this reflex alteration of nutrition. As this is true, it seems to me absurd to state that it is impossible to conceive how an external counter-irritant can affect the nutrition of a deep-seated organ.

It is evident that in all the cases which have been mentioned of external irritation causing disease in a distant organ there is no direct communication between the part irritated and the organ which is secondarily affected. And clinical experience confirms the evident deduction from this,—i.e., that it is impossible to determine, except by experiment, where the counter-irritant should be placed to affect most powerfully any given organ. It has, however, been clinically demonstrated that the general law for deep-seated parts is that the revulsant should be put directly over the part. When a superficial action is desired, other directions are needed. We are indebted to Dr. Anstie for pointing out what appears to be another law,—namely, that when a superficial part supplied by the anterior branches of a spinal nerve is to be affected, the counter-irritant should be placed over the posterior roots of the nerve. Not only can obstinate neuralgia often be relieved by this reflex action, but also the inflammatory changes so often coincident with intercostal neuralgia. The law seems also to apply to cervical nerves, since the proper position for the blister in facial trigeminal neuralgia is back of the ear or on the nape of the neck. Dr. A. Dumontpallier affirms that the best results of counter-irritation are obtained by applying the counter-irritant upon the opposite side of the body, so as to be exactly symmetrical with the pain, and especially commends hypodermic injection of water as a counter-irritant (*Gaz. Hebdomadaire*, Nov. 14, 1879).

Counter-irritants may be conveniently arranged under two heads: first, those which produce a decided structural alteration of the skin, including *epispasties*; second, those which do not provoke decided alterations of dermal structure, the *rubefaciants*. The indications for the use of these substances can best be considered under their respective headings.

As is well known, any sthenic inflammation, if of sufficient extent and intensity, may excite the general system even to the point of high fever. In this respect inflammation of the skin does not differ from that of other organs. Hence dermal irritants have a direct tendency to arouse or excite the system, and may be used as general stimulants. It will be seen at once that it is the nervous and arterial systems which alone feel their influence. Hence the irritants should not be relied upon in cases of exhaustion, for the only possible source of absolute increase of power to the system is in food; and in exhaustion those stimulants should be employed which increase the power of assimilating food. For this reason, external irritants are useful as stimulants in conditions of depression rather than of exhaustion. Such conditions of depression exist in *acute collapse* from any cause, in "*shock*" following injuries, in

the first stage of *pernicious malarial fever*, in *snake-bite*, and in other cases when the powers of the system are seemingly overwhelmed by some depressing agency. The rubefacients are preferable to blisters for this purpose, because their local after-effects are comparatively so trifling that they can without injury be applied to a very large extent of the surface.

EPISPASTICS, *vesicatories*, or, more colloquially, *blisters*, are substances which are used by the physician to produce that peculiar inflammation of the cuticle and outpouring of serum known as a blister. The immediate effect of a blister is more severe and more permanent than that of a rubefacient. Blisters are especially useful in inflammations of serous membranes, such as *pleuritis* and *peritonitis*; are very strongly recommended by some practitioners in parenchymatous inflammations, such as *pneumonia*; and are often of service in *neuralgia*, and in other forms of nervous irritation, such as the *maniacal delirium* of fevers, when dependent upon the irritant action of a blood-poison, and not upon exhaustion. The amount of serum which is poured out from a blister is sometimes quite large, and vesicants have even been used to relieve *dropsy*. In general dropsy their use is simply unjustifiable; but in *local dropsies*, as, for example, serous effusion into the pleural sac or into the pericardium, dependent upon local disease, they often do good, not only by affecting favorably the disease-process, but also by hastening the removal of the effusion.

In some chronic affections, long-continued severe counter-irritation is required: in such cases a blister may be "kept open" by the use of stimulating ointments, such as the *unguentum mezerei*. In *chronic inflammation* of the joints, repeated blistering is very often of service. When the inflammatory action is rheumatic, in my experience better results are obtained by repeated blistering than by keeping a blister sore by means of irritants. In *neuritis*, whether rheumatic or otherwise, blisters are often of service: they should be applied as a long narrow strip along the course of the nerve. In obstinate local *neuralgia*, very mild blistering over the seat of pain, or in accordance with Anstie's law, is sometimes advantageous.

The *contra-indications* to the use of blisters are high arterial and febrile excitement and a decided want of vital power. In the former case, the irritating influence which they exert upon the general system may increase the constitutional disturbance to such an extent as to do far more injury than any local benefit derived from them can do good. When the vitality is very weak, blisters may give rise to sloughing ulcers, which, refusing to heal, may waste very seriously the already-exhausted system. Hence, in all acute diseases of such type that the nutritive forces are exceedingly depressed, blisters must be avoided, or must only be used with great caution. For the same reason, great care must be exercised in their employment in the very young or the very aged. Very rarely indeed is a blister called for in the case of a young

infant, and, when employed, it should be allowed to remain in contact with the skin only just long enough to produce slight redness, and the complete vesication should be obtained by the use of the poultice.

There are various substances which are capable of producing vesication, but the only one in ordinary use is cantharides. In cases of emergency, a blister, it is said, may be raised in a very few minutes by the use of the *stronger water of ammonia*, a little of which is to be kept in contact with the skin by means of an inverted watch-glass. It is necessary to watch the process closely, and to remove the irritant as soon as vesication has occurred, as the ammonia is very capable of causing sloughing.

CANTHARIS—CANTHARIDES. U.S.

The dried bodies of the *Cantharis vesicatoria*, a beetle inhabiting Southern Europe, and coming into commerce in Spain, Italy, Sicily, and the southern provinces of Russia. *Spanish flies* are from half an inch to nearly an inch in length, and two to three lines in breadth, and have a large heart-shaped head, and brilliant metallic-green elytra, or wing-cases. Their odor during life is very strong and fetid, but is almost entirely lost in drying; their taste is urinous, very burning, and acrid. They are taken in May and June, when they swarm on the trees which they affect, by beating the branches early in the morning, when the insects are torpid from the cold, catching them upon linen sheets, and plunging them into hot vinegar-and-water, or exposing them to the fumes of boiling vinegar. In some places they are gathered by smoking the trees with the fumes of burning brimstone. When ground, Spanish flies afford a grayish-brown powder, full of minute greenish spangles, the remains of the feet, head, and wing-cases. The active principle of cantharides is *Cantharidin*, which occurs in white crystalline scales, is inodorous, tasteless, insoluble in water, nearly so in cold alcohol; soluble in ether, benzole, the oils, and very freely so in chloroform. Notwithstanding the insolubility of pure cantharidin, Spanish flies yield their virtues to alcohol and to water.

PHYSIOLOGICAL ACTION.—When a minute therapeutic dose of cantharides is taken, no perceptible immediate result is produced, and after a somewhat larger quantity the only symptom is usually some burning and pain in urination. Doses more than just sufficient to induce this should not be employed in medicine, as the symptoms produced by large amounts of the drug are exceedingly severe and distressing. Cantharides is very irritating, and, when applied to the skin, causes at first redness, with burning, then free vesication and severe pain, and, if the contact be longer maintained, deep inflammation and sloughing. Upon the mucous membranes it produces a no less intense effect; and consequently gastro-intestinal inflammation forms a prominent symptom of poisoning by it. Further, the active principle or principles are undoubtedly absorbed and are eliminated by the kidneys, coming in con-

tact with almost the whole genito-urinary mucous membrane: hence intense irritation and inflammation of these organs always result from the ingestion of an overdose of Spanish flies.

Very soon after a toxic dose of cantharides has been taken, the sufferer is seized with burning in the pharynx and cesophagus, and a sense of stricture in the throat. The pain soon spreads to the stomach, and vomiting comes on. The symptoms rapidly increase in severity; the abdominal pain becomes very severe, and, in the majority of cases, purging takes place. The matters rejected by the stomach are first mucous (with, if the drug have been taken in powder, little greenish specks through them), then bilious, and finally bloody. The stools are mucous, then fibrinous, bloody, becoming often very scanty, but excessively numerous, and in their passage accompanied by great tenesmus. Probably in most cases, very early in the attack severe salivation is developed, and is frequently accompanied by great swelling of the salivary glands. Sometimes death occurs in a very short time, from collapse produced by the intense gastro-intestinal inflammation; but more generally it is postponed for some hours, and a new train of symptoms arises. Aching pains in the back, and very frequent micturition, indicate the commencing urino-genital irritation. These symptoms increase in intensity until there is a constant irresistible desire to urinate, with violent tenesmus of the bladder, and yet an inability to pass more than a few drops of urine, which is albuminous, and not rarely bloody. In some cases there is a violent erotic excitement, an unquenchable lust, accompanied in man by numerous seminal emissions; violent priapism, swelling and heat of the organs, and even severe inflammation of the parts, indicate the intensity of the local action of the poison; sometimes gangrene ultimately occurs.

Neither amatory desire nor true priapism is, however, a constant symptom in cantharidal poisoning (cases, *Journ. de Pharm. et de Chimie*, June, 1871): indeed, the former is probably absent in the majority of cases. Consciousness and general power are often long preserved amid intensely severe local symptoms and agony, but, if the dose have been large enough, sooner or later collapse comes on, with the usual accompaniments, and the prostration deepens into complete powerlessness, stupor, coma, and finally death. In some cases violent hydrophobic delirium and severe tetanic convulsions are said to have occurred (Tardieu). Paraplegia has been noticed in several cases by Dr. Pallé (*Journ. de Pharm. et de Chimie*, June, 1871): it was probably reflex in its origin, and due to the intense irritation of the genito-urinary organs.

In animals, cantharides produces very much the same symptoms as in man. In dogs, according to the experiments of Orfila and of Beaupoil, the symptoms of gastro-intestinal inflammation are more prominent than those of irritation of the genito-urinary tract. It has been asserted that the lack of erotic excitement in these cases shows that the medicine acts differently upon man and upon animals. As already stated,

however, erotic delirium is very generally absent in fatal poisoning in man, while Schroff states that ten drops of the tincture of cantharides will frequently produce great sexual excitement in man, and the whole drift of the evidence is that libidinous desires are much more apt to be caused by amounts of Spanish flies but slightly toxic than by fatal doses. Indeed, the irritation caused by the latter would seem to be too intense, the general perturbation too great, for erotism to be induced. There appears to be some difference in the effects of different doses of the drug upon animals. Fatal doses very generally do not excite sexual desire; but Schubarth (quoted by Stillé) found that small doses do cause evident salaciousness and irritation of the genital organs, while, according to Husemann (*Handbuch der Toxicologie*, 1862, p. 264), the peasants of Northern Germany habitually give cantharides to cows when backward in coming into heat at the proper season. According to Dr. Cautieri (*Schmidt's Jahrb.*, Bd. clxv. p. 237), toxic doses of cantharides rapidly lessen blood-pressure and the force of the cardiac pulsations, but markedly increase the pulse-rate. He found in animals killed with cantharides marked hyperæmia of the brain and spinal cord, and nephritis. M. Galippe (*Gaz. Hebdom.*, 1874, p. 439) noted inflammation of the alimentary canal, kidneys, and bladder.

THERAPEUTICS.—Cantharides is employed internally only for the purpose of influencing the genito-urinary organs; and sufficient has already been said in regard to this use under the headings of Diuretics and Emmenagogues. The external use of cantharides is simply as a vesicant; and the employment of blisters has been sufficiently considered in the general discussion of the class. Two points, however, seem worthy of notice here: first, that this drug affords the only practical means of blistering at our command; secondly, that when it is freely employed there is always some danger of the absorption of a sufficient amount of the active principle for strangury to be induced. In susceptible persons, therefore, care has to be exercised in the use of epispastics; and whenever active irritation of the kidneys exists, cantharidal blisters should not on any account be applied.

At the meeting of the Berlin Medical Society in March, 1891, Professor Liebreich advocated the use of salts of cantharidin in *lupus phthisis*, and other forms of tubercular diseases, making the claim that, under the influence of the cantharidin, exudation of blood-serum occurs around the point of previously existing inflammation, and that in tubercular diseases this exudation leads through excess of nourishment to rapid proliferation of normal tissue, and the healing of the ulcers in spite of the presence of bacteria. There seems to be grave doubt as to the correctness of this theory, since in the experiments of G. Coen (*Arch. d. Med. Exper. Pathol.*, iii., 1891), in which the cantharidin was injected into rabbits suffering with inflamed ears produced by croton oil, no watery exudation occurred from the capillaries. Moreover, whilst some clinicians have obtained favorable results, the general verdict

has been unfavorable, and already the method has gone out of vogue. (For literature, see *Schmidt's Jahrb.*, Bd. ccxxxi., and *Therap. Monatsch.*, Bd. v., vi.)*

Toxicology.—Sufficient has already been said about the symptoms produced by cantharides. The minimum fatal dose is not certainly determined, and probably varies very much. According to Stillé, twenty-four grains of the powder, taken in two doses, have caused fatal abortion, and an ounce of the tincture has destroyed life after the lapse of a fortnight. After death, intense injection, swelling, patches of exudation, loss of epithelium, and other results of inflammation are found along the whole tract of the alimentary canal; intense hyperæmia of the kidneys, with contraction and injection of the bladder, also usually exists. According to the experiments of Aufrecht (*Centralbl. f. Med. Wissen.*, 1882, xx. 850), all the forms of nephritis may be produced by cantharidin, but it is probable that in most cases of poisoning the first change is exudation of the white blood-corpuscles, rapidly followed by a desquamative nephritis, with profound alteration in the glomerules (see Dr. Ida Eliasschoff, *Virchow's Archiv*, xiv. 323).

There is no known antidote to cantharides, and the treatment of the poisoning must be conducted upon general principles. The stomach, if not already thoroughly emptied, should be evacuated at once by a stimulating emetic if the stomach-pump be not at hand. Large quantities of mucilaginous or albuminous drinks should be taken; and all oily substances should be avoided, as favoring the solution, and consequently the absorption, of the poison. Opium should be freely exhibited, especially by the rectum, to allay pain and relieve the strangury. For the latter purpose warm sitz-baths or general baths should be given. In some cases leeches to the epigastrium are advisable. When the suffering is very intense, the cautious use of anæsthetics seems to me not only justifiable, but imperative. In the stage of prostration, the measures to be adopted are those commonly practised in collapse from poison.

ADMINISTRATION.—The preparation of cantharides most commonly used for the production of a blister is the *Cantharides Cerate* (*Ceratum Cantharidis*, U.S.), which is best spread upon sticking-plaster in such a way as to leave a margin about an inch in width, which shall adhere to the skin and hold the plaster in its place. In order for a blister to "draw" thoroughly, it usually has to be left on some eight hours; but in most cases the same result can be achieved with less suffering by

* The following formula affords the potassium cantharidinate in a proper form for hypodermic use: Cantharidin, 1 part; caustic potash, 2 parts; distilled water, 1000 parts. Of this solution, 1 gramme (1 C.c.) may be injected daily, and carefully increased. In order to lessen the pain produced, a few drops of a ten-per-cent. solution of cocaine may be just previously injected. According to Heyring, when not more than two decimilligrammes of the cantharidin are injected no renal irritation is produced; three decimilligrammes will produce, however, violent disturbance. The treatment has been especially commended in the early stages of tubercular laryngitis and in lupus.

allowing the blister to remain only five or six hours, or until decided redness and slight vesication have been induced, and then applying a flaxseed poultice. In certain localities vesication requires a much longer application than that just spoken of: thus, upon the shaved scalp a blister will rarely act efficiently in less than twelve hours, and often not in that time. In maniacs, in the delirious sick, in children, and in other unruly patients, it is often necessary to put on a blister in such a way that the sick person has no control over it. For this purpose the *Cantharidal Collodion* (*Collodium Cantharidatum*—60 per cent. U.S.) * may be used. It is ordinary collodion impregnated with cantharidin, and on evaporation leaves an adhesive blistering film: two or three coats of it should be applied by means of a camel's-hair brush. When there is any especial danger to be feared from absorption of the active principle, the use of the poultice, after a brief application of the blister as described above, should always be practised. The *Ceratum Cantharidis*, U.S., when spread upon skin or adhesive plaster, forms the ordinary "blister." The *tincture* (*Tinctura Cantharidis*—5 per cent. U.S.) is used internally in doses of three to five drops.

* For a case of poisoning by cantharidal collodion, see *Phila. Med. Times*, iv. 312.

FAMILY XII—RUBEFACIENTS.

RUBEFACIENTS are those remedies which are employed for the purpose of producing not any permanent inflammation of the skin, but a general intense irritation, redness, and congestion, which shall exert a temporary influence, whose power is the result of the large surface affected, and not of any permanent impression upon the nutritive acts of that surface. Most, if not all, rubefacients are capable of causing disorganizing inflammation if allowed to remain for too long a time in contact with the skin.

The superiority of rubefacients over blisters when it is desired to arouse or stimulate the system has already been pointed out (see p. 898). It remains to speak of the use of rubefacients in local diseases. They are especially useful in sudden cases of severe pain due, it may be, to acute congestion of a part or to some internal irritation, like that of gout. Thus, in the ordinary intestinal pain caused by irritant articles of food, or more commonly by a rheumatic, gouty, or other irritation following exposure to cold or wet, rubefacients are most useful. In this as in all other cases of what may be termed temporary functional derangement, when a counter-irritant is desired, rubefacients are superior to blisters, because their effects are not nearly so lasting, and also because, for the time being, they seem to impress more powerfully the nervous system, breaking up, as it were, the concentration of nervous energy, or calling off the irritation, or impressing the nervous system in some way which in our present ignorance it is difficult to find terms to express. A correct idea of the difference in the use of the two classes of counter-irritants can perhaps be conveyed by saying that when profound local alterations of nutrition are to be dealt with, blisters are to be used; when functional disturbance is to be met, rubefacients are to be employed. Blisters are useful in inflammations; rubefacients, in congestions. Yet this rule cannot be applied with rigidity.

SINAPIS ALBA—WHITE MUSTARD. U.S.

SINAPIS NIGRA—BLACK MUSTARD. U.S.

The seeds of *Brassica alba* and *Brassica nigra* respectively,—European crucifers, cultivated in the temperate regions of the world. These seeds are minute, globular bodies, yellowish within: they are to be distinguished one from the other by the smaller size, external brown color,

and more fiery taste of the black mustard, and the light-yellowish exterior of the white mustard.

Black Mustard contains *Myronic Acid* in combination with potash, and also a peculiar albuminous principle, *Emulsin*. When to these substances water is added, a reaction occurs, resulting in the production of a volatile oil out of the myronic acid. *Volatile oil of mustard* is a colorless or yellowish fluid, of an intensely pungent, or even corrosive, odor and taste. A momentary contact with it suffices to redden and blister the skin, and mucous membranes are said to be rapidly destroyed by its vapors.

White Mustard does not yield on distillation with water a volatile oil (*Oleum Sinapis Volatile*, U.S.), but contains an acrid fixed principle. The chemistry of white mustard seeds appears not to have been certainly determined. In 1825, Henry and Garot discovered a substance in them—*Sulpho-sinapisin*—which, according to Husemann, has been variously designated as *Sinapin*, *Sinapisin*, *Sinapinic Acid*, etc., but has been demonstrated by Babo and Hirschbrunn to be an alkaloid which also exists in the seeds of the black mustard. Robiquet and Boutron believe that the acrid fixed principle of white mustard is formed by a reaction between this and water in the presence of the emulsin.

THERAPEUTICS.—Mustard affords a most excellent material for the practice of mild revulsion. One great advantage it possesses is the ease with which it can be controlled,—all grades, from the mildest impression up to severe blistering, being at the will of the practitioner. It should be remembered, however, that the blister produced by it discharges but little, and is exceedingly sore and painful, as well as very slow and difficult of healing: so that, as an epispastic, mustard is in every way inferior to cantharides, and should not be employed. The black mustard is much stronger than the white, and must usually be diluted at least one-half (by the addition of flour or of flaxseed meal). The white variety may sometimes be employed pure, but generally it also should be reduced in strength.

In many cases it is desirable to maintain for hours a mild, equable counter-irritant impression; and this may be done by adding from one to three teaspoonfuls of mustard, more or less, to a poultice of flaxseed. A mustard poultice half-and-half black mustard, three parts to one white mustard, and flour, may generally be left on from twenty minutes to half an hour without danger of blistering. Weaker preparations may be used longer. A mustard plaster may be prepared like an ordinary poultice; but a very convenient method is to take a newspaper folded to a little larger than the desired size, and tear open the front piece so that it can be folded back like a flap, leaving one edge attached; next, to spread upon the thick portion the mustard, leaving the edges free, and then to close the flap upon it and fold the edges back to the desired shape: when done with, this plaster can be thrown away, and no rags are lost. The mustard draws well through the

single layer of newspaper covering it, but is, I think, less apt to leave troublesome after-soreness than when employed in the usual manner. *Charta Sinapis*, U.S., or *Mustard Paper*, consists of black mustard mixed with solution of gutta-percha and spread upon stiff paper four inches square. It is not so good as the domestic plaster, because not so easily regulated as to power and size.

Capsicum and the *stronger spices* afford excellent materials for rubefaction. Cayenne pepper is probably as strong as mustard, but is much less pleasant to handle, on account of the readiness with which it is diffused, and is much less frequently employed. *Spice-plasters* are useful when it is desired to make a steady, continuous mild impression, as in certain abdominal complaints. They may be made by the apothecary by means of the following recipe: Take of powdered ginger, ℥ii; powdered cloves and cinnamon, each, ℥i; Cayenne pepper, ℥ii; tincture of ginger, f℥ss; honey, q. s.; mix the powders, add the tincture, and sufficient honey to make of proper consistence for a stiff cataplasm. The domestic spice-plasters are much more elegant and cleanly than those made on the above plan. They are to be prepared as follows. Take equal parts of ground ginger, cloves, cinnamon, and allspice, and one-fourth part of Cayenne pepper, and thoroughly mix them; then put the resulting dry powder into a previously-prepared flannel bag of the desired size, distribute the powder equably through the latter, and quilt it in,—i.e., run lines of stitching across the bag, so as to confine the powder in little compartments. When used with common whisky or with alcohol, a plan which has seemed to me still more pleasant is to put two ounces of *unground* ginger, an ounce of unground cloves, cinnamon, and chillies, or African peppers, in a pint bottle, and pour the whisky upon them. After this has stood awhile, the liquor is to be put upon a piece of flannel of the proper size, and the latter is to be laid upon the part and covered with a larger piece of oiled silk, or else a piece of spongiopilin may be employed. If the strength of the preparation is too great, it can readily be reduced by dilution; if it is too little, it can as readily be increased by adding more of the spices, especially of the peppers. In many cases, when the tenderness is very great, the weight of the spice-plaster is objected to. Under these circumstances the substitute here proposed is especially valuable.

OIL OF TURPENTINE is a very powerful rubefacient, capable, if applied to the skin for too long a time, of destroying the epidermis. It produces, when properly used, simply an intense diffused redness. The most frequent mode of application is in the form of *stupes*, which should be made by dipping a piece of flannel, previously wrung out with warm water, into a cup of turpentine which has been warmed by setting it in hot water, and then wringing out all excess of the turpentine, and applying. These stupes may be left on from ten to thirty minutes, ac-

according to the severity of the impression desired and the susceptibility of the patient's skin. On some persons the least contact of turpentine, or even of its vapors, produces a most painful furuncular eruption. Where this idiosyncrasy exists, of course the remedy should never be used. The official liniment (*Linimentum Terebinthinæ*, U.S., *Kentish Ointment*) is used as a stimulant application to burns. According to the U.S. Dispensatory, it should be applied as soon as possible after the reception of the burn, by covering the injured surface with pledgets of patent lint saturated with it, and should be allowed to remain on until the peculiar inflammation excited by the fire has subsided.

AMMONIA is a most efficient rubefacient, which in its general relations has been sufficiently discussed elsewhere. When great haste is required, it may be employed as an epispastic by applying a piece of common lint saturated with the strongest water of ammonia, and covering it with some impervious coating. Great care must be practised lest the ammonia act as an escharotic, since a too prolonged application may produce a deep slough. To raise a blister requires from five to ten minutes. On account of its cheapness and efficiency, ammonia is very largely used in extemporaneous liniments. In prescribing, it must always be borne in mind that there are two waters of ammonia,—*Aqua Ammoniac Fortior*, U.S., with a specific gravity of 0.90, containing twenty-eight per cent. by weight of the gas, and *Aqua Ammoniac*, U.S., with a specific gravity of 0.960, containing ten per cent. by weight of the gas. The rubefacient action of ammonia is less permanent than that of turpentine. The liniment (*Linimentum Ammoniac*, U.S.) is composed of three hundred and fifty parts of ammonia water, fifty parts of alcohol, and six hundred parts of cotton-seed oil.

PIX BURGUNDICA, U.S., or *Burgundy Pitch*, is a concrete juice obtained by wounding the *Abies excelsa*, or Norway spruce,—lofty forest-trees of Middle and Northern Europe,—melting the product of the exudation with hot water, and straining. It is hard, opaque, brittle, of a feeble terebinthinate odor and taste, and contains resin and a minute amount of volatile oil. It is a mild rubefacient, which, in the form of plaster, may be kept applied for a long time in chronic bronchitis and in rheumatic affections of the trunkal muscles. The official plaster (*Emplastrum Picis Burgundicæ*, U.S.) contains fifteen per cent. of wax. The Warming Plaster (*Emplastrum Picis Cantharidatum*, U.S.) contains one part of cantharides cerate to twelve parts of Burgundy pitch, and is a very decided counter-irritant, whose prolonged use will sometimes blister.

FAMILY XIII.—ESCHAROTICS.

ESCHAROTICS are drugs which are used to destroy diseased or sound tissue. Many of them exert a purely chemical influence, while others seem to destroy life by directly affecting the vitality of the part, and are said to act dynamically. Those which act chemically do so in several ways: some, like bromine, probably produce an intense corrosive oxidation, while others, like sulphuric acid, abstract the water.

Escharotics are used for various purposes. Formerly they were employed to open abscesses; but in the very few cases in which the knife is not allowable, as in abscess of the liver, aspiration affords, without doubt, a much superior and, in *hepatic abscess*, much safer method. They are constantly applied to destroy unsound, harmful tissues and growths. Thus, they are used to remove the specific tissue of a *chancre*, or to kill a *malignant* or *semi-malignant tumor*. Another purpose which they fulfil is the destruction of *poisoned wounds*. In these cases they may in some instances destroy the poison itself, but at other times they simply prevent the absorption of the toxic agent by putting an end to the life-actions of the tissue containing it. It is hardly necessary to mention all the various cases in which caustics are employed to overcome the effects of poisoned wounds. *Hydrophobia* is a perfectly uncontrollable disease; but the thorough destruction of the wounded tissue at any time before the manifestation of the symptoms will probably prevent its occurrence, as it will certainly do if performed early. In *malignant pustule*, life depends upon the free early use of escharotics. Escharotics are employed to produce ulcerations which shall be the bases of *issues*; also, by destroying the exuberant granulations or the indolent surfaces of *ulcers*, to remove at the same time diseased tissue, afford protection to the parts below by forming an impermeable surface, and exert such alterative action upon the part as shall modify for good the life-processes.

It is evident that the choice of the caustic should depend upon the object to be attained. When large tumors are to be killed, or when it is all-important completely to destroy a poisoned wound, a powerful deep-reaching escharotic must be employed; but when the surface of an ulcer is to be filmed over, a caustic which acts superficially and forms a dense albuminous coating, as does nitrate of silver, is to be chosen.

An observation of Drs. N. A. Randolph and S. G. Dixon (*Med. News*, Jan. 4, 1885) indicates that the pain produced by a caustic may

be almost nullified by the use of cocaine. They find that the saturated solution of cocaine in nitric acid acts as powerfully as nitric acid although much more slowly, and that the only sensation experienced during the production of even a deep eschar is a slight prickling.

All of the more powerful of the escharotics, when taken internally in sufficient amount, act as violent corrosive poisons, producing agonizing pain in the œsophagus and hypogastrium, violent bloody vomiting, often purging of similar character, and finally collapse, deepening into death, which is sometimes preceded by convulsions. When the dose is not so large, the system may rally from the immediate effects of the poison, to succumb finally to the local lesions produced, or to struggle through a protracted convalescence to health, perhaps only to die years afterwards from organic stricture, caused by the ulcerations of the œsophagus or other of the digestive tubes. The first indication in poisoning by one of these substances is to neutralize or chemically antidote the poison. Many, if not all, of the escharotics have some chemical antidote: with the alkalies, dilute acid, generally convenient in the form of vinegar; with the acids, alkalies, generally at hand in the shape of whitewash or of soap; with others, specific substances, which, as antidotes, should be at once exhibited. Opium should always be freely given, and the symptoms during and after the first poisoning be treated as they arise.

POTASSA, U.S.—*Caustic Potash* is officinally prepared by boiling liquor potassæ until ebullition ceases and the potassa melts, when it is run into cylindrical moulds. It occurs in grayish semi-transparent sticks, about three inches long and as thick as a large goose-quill, very deliquescent when exposed to the air, and extremely soluble, except impurities (lime, oxide of iron, and potassium carbonate, etc.), in both water and alcohol. When it is placed upon the skin it soon melts, and, as it does so, gives rise to a pain which increases until it becomes very intense, and continues until the power of the alkali is so lost that it can no longer reach through the tissue it has killed to the sound flesh below. Under the action of the escharotic the skin becomes of a dirty ashen-gray, and finally a slough is formed, with inflammation of the surrounding parts, and ulceration and detachment of the dead tissue in from six to ten days. The potash appears to act chiefly by abstracting the water, and, to some extent, by combining with the fatty and other portions of the tissues. Its slough being perfectly permeable, and its power being but slowly expended by its own action, potash is one of the most thorough of the escharotics: it is, therefore, to be preferred when a very deep and decided influence is required, as after the bite of a *rabid dog*. It is somewhat uncontrollable in its action, and requires care in its use. The best method of application is as follows. Take a piece of heavy adhesive plaster, and cut a hole in it of such size that, when the piece is warmed and properly placed upon the

skin, the part to be acted upon will be exposed while all around it will be protected. Then apply the plaster, and grease the outer surface of it, without allowing any of the oil to come in contact with the exposed central skin. Then lay the caustic potash upon the latter, and, when the action is believed to have extended deep enough, wash the part with dilute vinegar.

POTASSA CUM CALCE, U.S.—*Vienna Paste* is a grayish-white powder, composed of equal amounts of caustic potash and caustic—i.e., unslaked—lime. It is not so active as caustic potash, but is less apt to spread and diffuse itself. It is to be mixed with sufficient alcohol to form a paste, and then applied like caustic potash. M. Piedagnol affirms (*Journal de Pharmacie et de Chimie*, 3e sér., t. xxxiii.) that this caustic may be rendered nearly or entirely painless by mixing one part of morphine hydrochlorate with three parts of the powder, and then by the addition of chloroform forming a paste that may be spread upon lead-plaster and so applied. In five minutes the skin under the application becomes of a dead-white color, and at the end of fifteen minutes is brown and carbonized. If the application be persisted in, the thickness of the eschar will become finally about equal to that of the layer of the paste employed.

ACIDUM ARSENIOSUM.—As a caustic, *arsenic* is energetic and powerful, but somewhat slow, and causes intense pain, with violent inflammation of the neighboring parts. It is stated to affect more rapidly morbid than normal structures, and is especially used for the destruction of malignant growths. It appears to act chiefly upon the vitality of the part, acting, when sufficiently diluted, as a powerful irritant, and when in a concentrated form producing an irritation so intense that life cannot endure it. Hence, probably, the reason of its affecting more rapidly morbid growths, which have a lower vitality than sound tissues.

The great objection to the employment of arsenic is the possibility of its absorption in sufficient amount to cause constitutional symptoms: even death has resulted from its external use. Since absorption takes place much more rapidly in a healthy than in an intensely inflamed or a dead tissue, whenever arsenic is employed as a caustic it should be used so freely as to kill the tissues rapidly; and under no circumstances should it be applied to a fresh wound.

Used in any way, arsenic is a hazardous caustic, and it ought to be employed only with the knowledge and distinct remembrance of this fact. Cancer, and perhaps some forms of semi-malignant ulceration, such as *lupus*, appear to be the only diseases which justify its use. Sir Astley Cooper's *Arsenious Ointment* consists of one drachm of arsenious acid, one drachm of sulphur, and an ounce of spermaceti cerate, and is to be allowed to remain in contact with the morbid growth for twenty-four hours.

The *Arsenical Paste of Frère Cosme and Rousselot*, which is officinal in France, is composed of one part of arsenious acid, two of dragon's blood, and two of porphyryzed cinnabar, made into paste with mucilage when applied. There is no reason for believing that any of the almost innumerable substances which have been proposed as a basis for arsenious pastes possess peculiar advantages: the only needful direction is to mix the caustic with from eight to ten times its bulk of inert material of such a nature as to make either an ointment or a paste, and to allow this to remain on for from eighteen to twenty-four hours.

ZINCI CHLORIDUM, U.S.—*Zinc Chloride* is made by the action of muriatic acid upon zinc. It occurs in broken fragments of a grayish white color, translucent and waxy in appearance, of an acrid corrosive or, when diluted, acrid astringent, metallic taste. It is extremely deliquescent, fusible, volatilizable at a high temperature, and very soluble in both water and alcohol. Zinc chloride is a very powerful caustic producing, when applied in a concentrated form, intense pain lasting for six to eight hours, and a whitish eschar, which usually separates in from six to twelve days. Its penetrating powers are said to be a little less, and its action more readily controlled, than that of potash; its absorption does not endanger life, as is the case with arsenious acid, and it leaves a slough which is free from odor.

Canquoin's Paste is made by mixing zinc chloride with flour and water. The strength varies according to the purpose, the weakest paste containing only one part of the caustic in six parts; the strongest, one part in three. When used, ten or fifteen drops of water are added to the paste, which is applied in layers, successive applications being required when a large tumor is to be destroyed. Anhydrous calcium sulphate has been especially commended by Dr. A. Ure, as forming a drier paste with the escharotic and limiting its action more definitely to the site of application than any other substance. Concentrated alcoholic or watery solutions of zinc chloride are often used as caustics in cases of *chancres* and other small *specific ulcers*, and are reputed to be efficient. They should be applied by means of little pledgets of lint. As the action of the chloride upon the skin is slow and very painful, whenever the cuticle over the part to be destroyed is sound it should be removed by means of blisters. By some surgeons the escharotic is introduced directly into the tumor to be destroyed. Thus, Maisonneuve makes a paste of one part of the chloride with three of flour and a little water, then cuts these into pointed strips or "arrows" and dries them. He then thrusts these hardened bodies into the tumor—if necessary, first making incisions with the bistoury—in such a way that they lie close together and form a ring around the base of the tumor. A continuous slough is thus created, which cuts off the remainder of the mass from the sound tissue and causes its death. Sometimes Maisonneuve simply thrusts these arrows into the

body of the tumor and destroys it directly. The official solution (*Liquor Zinci Chloridi*, U.S.) is used as a disinfectant.

HYDRARGYRI CHLORIDUM CORROSIVUM, U.S.—*Corrosive Sublimate* is an escharotic of moderate power, which shares the dangers of arsenic, since death has followed its external use. In saturated solution it is much used as a caustic in *chancres*, but is scarcely equal to the solution of mercuric nitrate. In these cases it should be applied by means of a camel's-hair brush. Professor George B. Wood formerly recommended very highly that in *onychia maligna* a powder composed of equal parts of corrosive sublimate and zinc sulphate intimately mixed should be sprinkled thickly over the diseased surface, and a pledget of lint thoroughly wet with laudanum laid thereon. There is severe pain for half an hour to an hour; but the dressings are not to be removed until eight or ten hours have elapsed. When the slough which is thus formed separates, a healthy granulating surface is left.

LIQUOR HYDRARGYRI NITRATIS, U.S.—*Solution of Mercuric Nitrate* is a nearly colorless, highly corrosive, acid liquid, having a specific gravity of 2.100, and made by dissolving mercury, or its red oxide, in a large excess of nitric acid. It contains free nitric acid and the binitrate of the deutoxide of mercury. I do not know of its external use ever having produced death; but it has caused salivation, and it is perfectly conceivable that its careless employment should lead to much more serious results: indeed, in the *Lancet* for Jan. 3, 1874, is reported a very serious case of poisoning by the application of the pernitrate to a space not bigger than a half-crown. It is rarely used, except for the purpose of destroying *specific* or *cancerous ulcers*. It is especially useful in *chancres*, to which it should be applied with a glass rod. In obstinate *acne*, a minute drop applied by means of a glass brush to the top of an indolent tubercle is said to destroy it without producing a scar. It has been largely employed by gynecologists in *ulcerations of the cervix uteri*. Its action is very prompt, and is moderately deep; the pain is severe, but transient.

ACIDUM SULPHURICUM.—*Sulphuric Acid* is a powerful escharotic, and was formerly used extensively for destroying even large growths. For this purpose the strongest acid is mixed with charcoal, so as to make a thick, manageable paste. Before the application of this, the skin should be removed by a blister.

ACIDUM NITRICUM.—*Nitric Acid* is a powerful caustic, which is never employed to destroy large growths, but is a favorite application to *chancres*, to *syphilitic*, *phagedenic*, and other unhealthy *ulcers*, and to *condylomata* and other small *dermal growths*. It is applied by means of a glass rod or a splinter of wood. A drop or two is usually amply

sufficient; and when the action has gone far enough, the part should be washed with soap-suds, which at once neutralizes the acid.

ACIDUM CHROMICUM, U.S.—*Chromic Acid* occurs in anhydrous acicular crystals, of a deep-red color, and an acid, metallic, corrosive taste. They are very deliquescent, melting down, when exposed to the air into a deep-red solution. Chromic acid is a very active oxidizer, and when mixed with organic matter rapidly alters it, and if in slight excess will dissolve almost any form of tissue. It is no doubt in this way that it acts as an escharotic. It is very much used to destroy *condylomata* and other *dermal growths*, and doubtless would be efficient in case of larger tumors. In superficial affections it is best applied by means of a glass rod, the liquid formed by the spontaneous deliquescence of the crystals being used. Chromic acid is sometimes prescribed dissolved in, or made into a paste with, glycerin, but it is stated that in mixing the two great care must be taken to add the liquid slowly drop by drop as otherwise there is danger of an explosion (*Phila. Med. Times*, iv). In the German army, painting the sole of the foot and the skin between the toes with a five-per-cent. solution of chromic acid is said to have had a very great influence in increasing the marching powers of the troops by arresting excessive sweating and hardening the skin (*Schmidt's Jahrb.*, Bd. 223, p. 20). Chromic acid is a violent corrosive poison; a single drop of the saturated solution has produced very severe symptoms (*Brit. Med. Journ.*, vol. i., 1889), and in a number of cases death has resulted from its too free external use.* (See *Stricker's Jahrbücher*, 1877, p. 139; *Schmidt's Jahrb.*, 1884, cci. 129; also *University Med. Magazine*, ii).

BROMUM, U.S.—*Bromine* is a dark-red liquid which has a very powerful, disagreeable, chlorine-like odor, and at ordinary temperatures emits exceedingly acrid, pungent fumes. It is sparingly soluble in water, more soluble in alcohol, and still more so in ether. When brought into contact with organic matter, it oxidizes and completely destroys it with great rapidity. On account of this property and of its liquid form, bromine is one of the most severe, thorough, and rapid of all the caustics. It has not been much employed to destroy morbid growths, but during our late war was found to be the most efficient of all the applications tried in *hospital gangrene*. After most of the slough had been cut away, the caustic was applied pretty freely to the living tissue by means of a glass rod. The pain was very severe, but transient. When taken internally, bromine acts as a very powerful corrosive poison. (For cases, see *Schmidt's Jahrb.*, Bd. 221; also *Vrtljschr. f. Gerichtl. Med.*, 1889.)

Zinc Sulphate, *Copper Sulphate*, and *Burnt Alum* are feeble escharotics, never used except to destroy *exuberant granulations* in ulcers.

* For experiments as to its effect on animals, see *Arch. f. Exper. Path. u. Pharm.*, vi; also *Stricker's Jahrb.*, 1877, p. 139.

FAMILY XIV.—DEMULCENTS.

THESE are bland substances, which form more or less gummy or mucilaginous solutions in water, capable of exerting a calming or soothing influence upon inflamed surfaces. Without doubt water itself is the demulcent *par excellence*; but the remedies here discussed do seem to enhance its power. It has been claimed for these medicines not only that they soothe surfaces to which they are immediately applied, but also that taken internally they relieve irritation in distant organs. As, however, all of them are complex vegetable products, as many of them are staple articles in the world's food, and as none of them have been detected in the blood or the secretions, it cannot be allowed that they reach distant parts through absorption into the blood. What is certainly true of some of them is probably true of all,—i.e., digestion of them occurs in the *primæ viæ*. The relief which undoubtedly follows their use in certain affections of parts which they can reach only through the circulation is probably in great part, if not altogether, due to the large quantities of water with which they are administered, which, passing through the body, lessen the concentration, and hence the acidity, of the urine and other secretions.

Clinically, demulcents are useful as local applications in all forms of acutely-inflamed surfaces, and they are taken internally in acute *inflammatory* conditions of the *alimentary canal*. In slight *bronchial* irritation they are often of service, especially when allowed to dissolve slowly in the mouth: used in this manner, they not only exert an influence upon the mucous membrane of the mouth, but very probably find their way also into the respiratory passages.

ACACIA—GUM ARABIC. U.S.

A gummy exudation from *Acacia Senegal*, a small tree growing in Northern Africa, Senegambia, Guinea, etc., the Cape Colony, and Australia. Gum arabic occurs in roundish or irregular pieces, more or less transparent, hard, brittle, varying in color from white or yellowish white to red, or even deep orange brown. It consists of a peculiar principle, *Arabin*, united with about three per cent. of lime, potash, and magnesia. According to Husemann, pure *arabin* is an amorphous substance, glassy and transparent when dry, but milk-white when

moist, and having a feeble acid reaction, with the power of uniting with bases. In the plant, arabin, like other gums, appears to be formed by a retrograde metamorphosis of cellulose. Indeed, Wigand declares that the flesh and even the hard endocarp of the plum can undergo this metamorphosis. The same investigator affirms that *bassorin* is the first product of the change, and is, by a continuation of the process, converted into arabin. On account of its solubility and pleasant taste, gum arabic is often used as a demulcent in irritation of the fauces and in *angina*. It is sometimes employed as an addition to drinking-water in fevers, and is believed to have slight nutritious properties. Its chief use, however, is in Pharmacy, in the making of emulsions, pills, &c. The *mucilage* (*Mucilago Acaciae*, U.S.) is official.

TRAGACANTHA, U.S.—*Tragacanth* is the concrete juice of *Astragalus gummifer*, and of other species of *Astragalus*, a small shrub of Asia Minor. *Tragacanth* occurs in large, whitish, horny, waved flakes, sometimes in filamentous pieces. It is odorless and nearly tasteless. Introduced into water it does not dissolve, but swells up into a soft paste. One hundred parts of it contain, according to Guerin, 53.3 parts of arabin, 33.1 parts of *bassorin*, and 2.5 parts of inorganic ash. *Bassorin* is a gummy principle, at once distinguished from arabin by its not dissolving in water, but simply swelling up into a pasty mass. *Tragacanth* is used only in the manufacture of troches and in suspending heavy powders, for which purpose the difficulty of its solution and the extreme viscosity of its *mucilage* especially fit it. Its *mucilage* (*Mucilago Tragacanthæ*, U.S.) is official.

ULMUS, U.S.—*Slippery Elm* is the inner bark of *Ulmus fulva*, a large indigenous tree. The bark is of a yellowish-white or tan color, fibrous, yet when dry somewhat brittle, and occurs in long, flat strips or pieces one or two lines thick. It is pleasantly mucilaginous when chewed. It contains a large quantity of a peculiar mucilage, which yields freely to water. Its infusion is sometimes taken in large quantities in inflammations of the intestines, as a demulcent laxative; but its chief use is as an external application. When ground into powder, slippery elm makes a very excellent soothing poultice. The *mucilage* (*Mucilago Ulmi*) is official.

CETRARIA, U.S.—*Iceland Moss* is the fronds of a lichen, *Cetraria islandica*, growing on rocks in Iceland and in most of the northern portions of the world. It is said to be abundant in the mountains of New England. The foliaceous, dry, shining, lobed, and lacinated fronds are about four inches long, of various intermixed colors, gray, brown, and red, of a mucilaginous, bitter taste. Iceland moss contains a peculiar starch-like principle, lichen starch, and a bitter principle. It is inodorous, and has a mucilaginous, bitter taste. It yields to cold water

its bitterness; to boiling water all of its virtues. *Cetrarin*, or *Cetraric Acid*, is the bitter principle, which may be obtained as a snow-white mass of interlaced acicular crystals. It unites with alkalies to form salts. With it in the lichen is associated in small quantities *lichstearic acid*. Prof. Kobert has found that cetrarin has no effect upon the arterial pressure; also that in toxic dose it produces violent convulsions in the cat and in the dog, whilst in small dose it distinctly increases the activity of the motor area of the brain and spinal cord. Prof. Kobert also claims that in healthy men cetrarin increases the number of the red and, in a still greater degree, of the white corpuscles; and believes that in *chlorosis* and *anæmia*, especially when there is constipation, cetrarin will prove a valuable remedy (*Verhand. d. Internat. Med. Congress, Berlin, 1890*). *Lichenin*, or *Lichen Starch*, the mucilaginous, nutritive principle of Iceland moss, differs from ordinary starch in not being deposited in granules within the cells, but in layers or irregular masses between the cells, or indeed forming the walls themselves of the cells (De Bary, *Hofmeister's Handb. der physiolog. Botan.*, Bd. ii. p. 255). In cold water it swells up without dissolving; in hot water it dissolves, and on cooling condenses into a jelly. With iodine it strikes a yellow, green, or sometimes rather faint blue, color. It is found in very many lichens; also in many species of sea-weed, notably in the so-called *Corsican moss*. Iceland moss has enjoyed some reputation as a demulcent in pectoral complaints. From its bitter principle, it is probably somewhat tonic, and its lichenin is probably about equal to ordinary starch as a nutrient. When prepared as an article of diet, in the form of jelly, the bitter taste should be removed by soaking for some hours in a very weak, cold alkaline solution, and afterwards for a little while in cold water. The decoction (*Decoctum Cetrariæ*) is official. A pint may be given during the day.

CHONDROS, U.S.—Irish Moss, or Carrageen.—The fronds of *Chondrus crispus*, and of *Gigartina mamillosa*, sea-weed growing on the coast of Ireland, and also on the northern coast of the United States, where it is now gathered in large quantities. The fronds are purplish red,—but, as kept in the shops, bleached by washing in fresh water, whitish, and translucent,—cartilaginous, slender, much branched, swelling up but not dissolving in water, and having a slightly saline taste. Their virtue depends chiefly upon a starch- or gum-like principle, *Carrageenin*, which is distinguished from starch by not turning blue with iodine, and from gum by not precipitating from its watery solution on the addition of alcohol. *Chondrus* also contains a notable proportion of a vegetable albumen.

Carrageen, being demulcent and nutritious, is employed as an article of diet in those cases requiring food of such character, and may be

used instead of arrow-root. It is to be prepared by first soaking for ten minutes in cold water, and then boiling from half an ounce to an ounce of it (according to the desired consistency) in a pint and a half of water down to a pint, sweetening and flavoring to taste. Milk may be substituted for water.

GLYCYRRHIZA, U.S.—*Liquorice Root* is the root of *Glycyrrhiza glabra* and *glandulifera*, native herbs of Southern Europe. It occurs in long cylindrical pieces, from a few lines to more than an inch in diameter, brownish externally and yellowish within. Its fracture is fibrous, its taste sweet and mucilaginous, its odor none. Its active principle is *Glycyrrhizin*. This is a sweet, neutral substance, differing from the sugars in not being converted by nitric acid into oxalic acid, and by its inability to undergo the vinous fermentation. Liquorice root is very largely used as a demulcent in pectoral complaints, and, on account of its pleasant taste, as a means of disguising or of flavoring medicines. In the form of glycyrrhizin it is said to conceal almost entirely the bitter taste of quinine and similar substances. It is used almost exclusively in the form of the *extract* (*Extractum Glycyrrhizæ, U.S.*), known as *Liquorice*. The *Mistura Glycyrrhizæ Composita, U.S.*, or *Brown Mixture*, contains paregoric, antimonial wine, and sweet spirit of nitre, and is much used as a domestic remedy in "colds" and the early stages of mild bronchitis. The dose for an adult is half a fluidounce to a fluidounce every three hours; for a child three years old, a teaspoonful. The *pure extract* (*Extractum Glycyrrhizæ Purum, U.S.*) and the *fluid extract* (*Extractum Glycyrrhizæ Fluidum, U.S.*) are excellent preparations. *Glycyrrhizinum Ammoniatum, U.S.*, is a very elegant demulcent preparation, which, however, is incompatible with acid or alkaline solutions: its dose is from five to ten grains. The *compound liquorice powder* (*Pulvis Glycyrrhizæ Compositus, U.S.*) contains senna and washed sulphur. It is an elegant laxative, acting, usually mildly and without the production of pain, in doses of one to two teaspoonfuls.

LINUM, U.S., or *Flaxseed*, is the seed of *Linum usitatissimum*, a common flax, and contains large quantities of mucilage and of oil: its *compound infusion* is much used internally. It is often made with boiling water; but the application of too much heat causes the extraction of more or less of the oil, and thereby renders the preparation less palatable. The infusion should never, therefore, be boiled during its making. The addition of lemon and sugar renders it more palatable. It may be drunk *ad libitum* in pectoral catarrhs, in enteritis and dysentery, and in irritation of the kidneys or the urinary passages.

MEDULLA SASSAFRAS, or *Sassafras pith*, yields a delicate mucilage much used in diseases of the eye (*Mucilago Sassafras Medullæ, U.S.*).

ALTHÆA, U.S.—The roots of *Althæa officinalis* yield a bland mucilage, their decoction is sometimes given in irritated states of the stomach and bowels, and their *syrup* (*Syrupus Althææ*, U.S.) is used as a vehicle.

TAPIOCA is the fecula of the root of *Janipha Manibot*, a native of South America. There are two varieties of the tapioca plant,—the *sweet* and the *bitter cassava*. The latter is in its fresh state poisonous, from the prussic acid which it contains, but yields most, if not all, of the tapioca of commerce. The tapioca is obtained by allowing the expressed juice to stand, separating the powder which deposits, washing, and drying by heat, owing to the action of which the starch is rendered partially soluble in cold water. It is in irregular, hard and rough, nearly tasteless grains, which the microscope shows to be composed of ruptured starch-granules.

MARANTA (*Arrow-root*) is a fecula or starch, obtained from the rhizome of *Maranta arundinacea*, a native of the West Indies. Arrow-root is produced in the West Indies, in Africa, and in the Southern United States, especially Florida. The most esteemed variety is that which comes from the island of Bermuda. It is obtained in the usual method by beating the root-stocks into a pulp, and the use of flowing cold water. It occurs as a very light, tasteless, and odorless white powder, which the microscope shows to be composed of ovate, oblong, or irregularly-convex granules, from the seven-hundred-and-fiftieth to the two-thousandth of an inch long, marked with very fine rings and with a circular hilum, which cracks in a linear or stellate manner. Arrow-root is often adulterated with other starches, which are best detected by the microscope.

For methods of preparing arrow-root and tapioca, see page 32.

SAGO is a fecula obtained from the pith of *Sagus Rumphii* and other sago palms of Sumatra and the neighboring regions. It is first prepared in the usual manner, and then formed into a paste with water, rubbed into grains, and dried. *Pearl Sago* occurs in hard, roundish, somewhat translucent or sometimes opaque grains, about the size of a pin's head. *Common Sago* is in larger and browner grains, often mixed with some powder. It is composed of oval or ovate, often truncate and muller-shaped, often much broken, starch granules. It is used exclusively as an article of diet, forming a jelly, which is best prepared as follows: Wash the sago well in cold water; put a small teacupful of it to soak in half a pint of water over-night, and in the morning put this mixture into one pint of hot water; squeeze into it the juice out of a thinly-pared lemon, and allow to simmer slowly for twenty minutes; then sweeten, add wine according to taste or the exigencies of the case, then pour into moulds to cool.

•

HORDEUM.—The decorticated seeds of the common barley constitute the *pearl barley* of commerce. They contain starch and mucilage and the *decoction* (*Decoctum Hordei*) was formerly official. *Barley water* is used as a nutritious, demulcent drink in fevers and inflammatory conditions, especially when the gastric mucous membrane is involved. The U.S. Pharmacopœia of 1870 directed that it should be prepared as follows: "Take of barley two troyounces; water a sufficient quantity. Having washed away the extraneous matters which adhere to the barley, boil it with half a pint of water for a short time and throw away the resulting liquid. Then, having poured on it four pints of boiling water, boil down to two pints, and strain."

FAMILY XV.—EMOLLIENTS.

True emollients are perfectly bland, fatty substances which, when applied to the skin, soften it and render it more pliable. The action of these remedies is largely mechanical, and they probably soften the derm in precisely the same way as they affect a raw hide or a piece of leather. They are therefore especially useful when the skin has a tendency to crack or to chaf. Whenever surfaces become sore by attrition, or, in other words, chafe, emollients are also useful mechanically. They often afford relief in simple inflammations of the skin under such circumstances that their action cannot be explained as purely mechanical: indeed, they seem to exert a dynamic influence upon the nutrition of the parts concerned. To the best of our present knowledge, the oxygen or other constituent of the air acts as a stimulant to exposed surfaces and increases inflammations there present; and it is believed that fatty matters do good by keeping out the air. If this be so, the apparently dynamic influence of fatty matters is, after all, mechanical. Be these things as they may, clinical experience has demonstrated that fatty matters are of very great value in the treatment of superficial inflammations. It must be borne in mind that the blandest fat, when it becomes rancid, is very irritating, and will do far more harm than good, so that the strictest attention must be paid to the condition of the fatty material employed. Any perfectly bland oily substance may be used as an emollient. *Mutton suet* and *goose-grease* are famous in domestic medicine, but are simply valuable because, if well prepared, they are less apt than some other fats to become rancid. It cannot be allowed that there is any difference in fats, unless it be in penetrating power: a very hard fat is of course not so readily applied as a softer one, and therefore only such fats as freely melt, or at least become very soft, at the temperature of the body, are to be used. *Common Lard* (*Adeps*, U.S.), when freed by washing from the salt which it commonly contains, is a mild fat, melting at the temperature of the body. It is enormously used in pharmacy. *Cacao Butter* (*Oleum Theobromatis*, U.S.) is an absolutely bland vegetable fat, which is a firm solid at ordinary temperatures, but melts with the heat of the body, and is consequently very largely used in the preparation of suppositories, both officinal and magistral. *Spermaceti* (*Cetaceum*, U.S.) is employed to give consistence to ointments, as is also wax (*Cera alba*, or *white wax*, and *Cera flava*, or *yellow wax*, U.S.). *Cold Cream* (*Unguentum Aquae*

Rosæ, U.S.), containing oil of sweet almonds, spermaceti, white wax, and rose-water, is one of the most elegant of the official emollients.

OLEA.—Of bland fixed oils the U.S. Pharmacopœia recognizes four. Of these, the *Oleum Amygdalæ Expressum*, U.S., or expressed oil of almond, is a pale, straw-colored or colorless, almost inodorous oil, with a mild nutty taste. It may be employed wherever a very pleasant emollient oily application is desired. Its use is largely restricted by its comparative expensiveness.

Oleum Lini, U.S., or linseed oil, is a yellowish oily liquid, with a peculiar odor and a bland taste. When exposed to the air it thickens and acquires a strong odor and taste. It is the least elegant of these oils, and is not often used in medicine, except when in fecal accumulations or other conditions large rectal injections of oil are required, when it is preferred on account of its cheapness.

Oleum Olivæ, U.S., or olive oil, is expressed from the fruit of the European olive; has a pale yellow or light greenish-yellow color, and a pleasant odor and taste. It is the ordinary salad oil of the table, and may be used wherever a very bland oil is desired. It has, however, no superiority for ordinary purposes over the *Oleum Gossypii Seminis*, U.S., or cotton-seed oil, which is expressed from the seeds of the ordinary cotton-plant; indeed, a very large proportion of the olive oil of commerce is cotton-seed oil: it is credibly affirmed that more cotton-seed oil is exported from New Orleans to the Mediterranean cities than olive oil is exported from those ports, most of the cotton-seed oil coming back with olive oil labels. There seems to be no sufficient reason for believing that olive oil differs from cotton-seed oil in its physiological or therapeutic properties. These oils are sometimes used internally with advantage, for nutritive purposes, and are also very mildly laxative. The assertion originally made by Dr. Kennedy, that large doses of olive oil are very useful against *biliary calculi*, has received sufficient clinical confirmation to entitle it to great weight. In experiments by Dr. J. Rosenberg upon dogs with biliary fistulæ (*Schmidt's Jahrb.*, 1890), it was found that olive oil not only increased the amount of bile, but also rendered the bile much more liquid. Since fats are absorbed chiefly, if not entirely, through the thoracic duct, it is plain that the oil must pass through the pulmonary circulation before reaching the liver. This is confirmed by the experiments of Chauffard, who could not find any trace of oil which he had injected into the stomach of the lower animal in the bile-duct or gall-bladder. If olive oil has the remedial influence claimed for it, it probably acts reflexly through the nervous system,—through a mechanism provided by nature for the purpose of aiding in the digestion of fats when in excess. The dose of the oil should be not less than from five to seven ounces, taken in four to eight portions in not longer than three hours. It may be given in aromatized emulsion with a little brandy or whiskey if desired.

LANOLIN is a fat obtained from the wool of sheep, which is said to contain, on an average, forty-five per cent. of it. It appears to be practically the same as the natural oil of the hair in man and other animals (see *Virchow's Archiv*, cxxi., 1890). It was first recommended by Dr. Oscar Liebreich as a basis for ointments or preparations to be applied to the surface of the skin. It is entirely free from irritant properties, has the power of taking up a large amount of water without losing its unctuousness, does not easily become rancid, and is asserted to be absorbed through the skin much more readily than are other fats. In the experiments of Dr. Patschkowsky (*Pharm. Zeit.*, 1885), half an hour after inunction with lanolin and iodide of potassium the iodine was recovered from the urine, while official iodide of potassium ointment yielded negative results. This has been confirmed by Kaspar (*Deutsche Med. Wochenschr.*, Dec. 1885), but Ritter and Pfeiffer obtained contrary results, and in a considerable series of experiments were unable to perceive that lanolin had any superiority over other fats in promoting absorption. The facts, moreover, that lanolin is largely the secretion of sebaceous follicles, contains an abundance of cholesterin, and is of the nature of a waste product, which is intended, not for absorption, but for the keeping soft of the skin and its appendages, indicate very strongly that it will yield itself, and medicinal properties with which it may be impregnated, less readily to absorption than do other fats.

GLYCERINUM—GLYCERIN. U.S.

This is a thick, syrupy liquid, colorless, free from odor, and of a sweet taste. It was originally prepared by heating together a metallic oxide and ordinary fats, as in the manufacture of lead-plaster. Chemically speaking, it belongs to the alcohols, and is known according to the recent nomenclature as *propenyl alcohol*. It is always set free during the process of saponification, when the stearic or other acids of the fat unite with some base to form salts known as soap. Consequently, glycerin always forms a considerable part of the soap-maker's waste; but in this it is so mixed with impurities that until recently it was valueless. Now, by means of certain patent processes, the glycerin is said to be obtained pure from the waste products of soap-factories. The great bulk of the glycerin in commerce is made by the direct decomposition of fats by heated steam.

Under certain circumstances, not well understood, glycerin forms hard, brilliant crystals. In its usual liquid form it mixes in all proportions with water and alcohol, and itself dissolves iodine, bromine, the alkalies, tannic and other vegetable acids, a large number of neutral salts, salicin, and other organic principles.

Glycerin does not evaporate upon exposure, but is very hygroscopic, and absorbs water from the air. When pure, it is incapable of becoming rancid or of fermenting spontaneously. The acrid glycerin

formerly so abundant, and still met with, owes its irritant properties to contaminating substances, especially, it is said, to oxalic and formic acids. The former of these substances is apt to be created by the action of the sulphuric acid used during the purification of the glycerin, the latter by the reaction between the oxalic acid and the glycerin.

PHYSIOLOGICAL ACTION.—When large doses of glycerin (in the dog eight or more parts per thousand by weight) are injected subcutaneously, death is produced in a period varying, according to the dose, from one hour to several days. The symptoms are loss of muscular strength, lethargy, bloody urine, vomiting, dryness of the mucous membrane, with marked thirst, fall of temperature, gradual extinction of both respiration and circulation, and finally convulsions and coma (Dujardin-Beaumetz and Audijé, *Bull. Thérap.*, xci. 62). The convulsions occur more early and severely when large doses are employed, and are then said to be tetanic, and to be accompanied with a decided rise of temperature. The fall of temperature is, even in the milder cases, present only late in the poisoning, and is sometimes, if not always, preceded by a rise. After death intense congestion, with more or less softening of the tissue, is found in the lungs, kidneys, and intestines. In man no symptoms of poisoning have ever been produced by glycerin, the largest single amounts ingested—an ounce or so—having no perceptible effect other than that of a laxative.

Catillon claims that glycerin administered in small continuous doses exerts a decided effect upon nutrition (*Bull. Thérap.*, xcii. 130; *Arch. de Physiol. Norm. et Path.*, 1877). In his experiments he found that eight grains given daily to guinea-pigs produced a very marked gain in weight, with a lessened excretion of urea. In man an ounce daily also produced in the elimination of urea a decided diminution, which was not increased by increasing the doses of glycerin. The appetite in many cases was, after a little time, much improved, and then the increased ingestion of food produced an increased elimination of urea. The fact that an increase of food was permitted in these experiments shows, however, that the conditions of experimentation were not rigid enough to allow much weight to be attached to the result; and the relation of glycerin to the elimination of urea has been investigated by L. Lewin (*Zeitschr. f. Biol.*, xv.), by N. Tschirwinsky (*Ibid.*), and by I. Munk (*Virchow's Archiv*, lxxvi. 130), with somewhat contradictory results. Of these experiments the most extensive are those of Munk, who seems to have used all proper precautions, and found that glycerin has no effect upon the elimination of urea or the general bodily nutrition. The results reached by Lewin correspond with those of Munk. Tschirwinsky omitted fatty materials from the food, and found that while at first the elimination of urea was diminished, it afterwards, under the use of very large doses of glycerin, was increased. With our present evidence it must be considered most probable that glycerin has no controlling power over the waste of nitrogenous tissues.

Glycerin is absorbed from the alimentary canal, and when freely administered is in part eliminated, and in part burnt up in the system. Both Ustimowitsch (*Archiv f. d. Ges. Physiolog.*, xiii. 453) and Plösz (*Ibid.*, xvi. 153) found a substance in the urine which they believe to be a derivative product of glycerin, while Catillon proved that it is not eliminated by the skin or, even when it purges, by the intestines. Catillon and Lewin recovered from the urine only a small proportion of that ingested, Tschirwinsky only 8.7 per cent., while Ludwig Arnschink (*Sitzungsb. Gesellschaft Morphol. Physiol. München*, 1886, ii., also *Zeitschr. für Biolog.*, xxiii. 413) found that not more than thirty per cent. escapes from the body. Since a large proportion of ingested glycerin is oxidized in the body, it would appear that it is capable of replacing to some extent true fatty carbohydrates for the production of heat or energy, and, therefore, has food value. According to the calculations of Arnschink, two hundred and nineteen parts of it are equivalent to about one hundred parts of fat. This view is corroborated by the work of Scheremetjewsky, who found in rabbits that the intravenous injection of glycerin was followed by an immediate increase of the consumption of oxygen, and of the giving up of carbonic acid. The work of Scheremetjewsky has given rise to considerable controversy, but the latest experiments, those of I. Munk, seem to lead to the conclusion that glycerin is capable of taking the place of the bodily fat. (For discussion, see *Archiv f. d. Ges. Phys.*, xlvii., 1889-90.)

According to Fuchsinger, the bloody urine produced by poisonous doses of glycerin contains an abundance of the coloring-matter of the blood, but no free corpuscles (*Pflüger's Archiv*, xi. 502). Very interesting in connection with the use of glycerin in diabetes is the assertion of Fuchsinger (*Pflüger's Archiv*, xii. 501; *Centralbl. f. Med. Wiss.*, 1877), that in rabbits slightly poisoned with glycerin no sugar appears in the urine after the "diabetic puncture." The experiments of Eckhard gave, however, a contrary result (*Centralbl. f. Med. Wiss.*, 1876, p. 273), and Catillon affirms that given in very large continuous doses glycerin increases the amount of sugar in the blood.

THERAPEUTICS.—Locally applied, glycerin is usually unirritating, and it is much employed as an emollient. The chief disadvantage that attends its use is its stickiness; on the other hand, its non-volatility and its hygroscopic properties give a persistency to its action which is often very advantageous. It enters largely into the composition of popular emollient ointments, or "creams," as they are called, and is often used itself for *chapped hands*, *excoriations*, and similar troubles. It is also employed by dermatologists to some extent in *chronic eczema*; in *seborrhæa*, whether affecting the hairy scalp or other parts, it is asserted to be especially useful, softening the masses of secretion, and, used in conjunction with such remedies as borax, zinc, and acetate of lead, diminishing the amount of secretion. When there is a want of sebaceous secretion, it is said also to act efficiently; in *scabies*, *pruritus*,

and even *psoriasis*, glycerin is used, diluted with water, as a vehicle for more active remedies. Upon the mucous membranes glycerin acts very much as it does upon the skin, and diluted with water is very useful in *coryza*, and even, by enemata, in *dysentery*; in *croup* or *laryngitis* it may with advantage be applied freely by means of a large camel's-hair brush to the orifice of the larynx, so as to run into the latter. In large active doses it is asserted to be very effective in *hemorrhoids*. It also forms an excellent basis for mouth-washes; or a paste may be made with it and borax, or similar substance, for use in ulcerations of the same cavity. The list of diseases in which this remedy is employed might be very much lengthened; but the examples already given are sufficient to indicate the range of its application as an emollient and as a vehicle. There are certain persons upon whose skin and mucous membranes even the purest glycerin seems to act as an irritant. This influence is most intense when the glycerin is nearly or entirely free from water. It is, however, discernible even when the remedy is much diluted, and often inhibits its use. The existence of this idiosyncrasy to glycerin can be determined only by trial.

When administered internally in doses of one or two ounces glycerin acts as a gentle but very uncertain laxative. I do not think that a single dose has any other perceptible effect. It was long ago proposed as a substitute for cod-liver oil in *cachectic diseases*, but failed to acquire reputation. Nevertheless, the results of Catillon would seem to demand for it more extensive trial. That observer states the proper amount of it to be half an ounce to an ounce in the course of the day, in three doses. It has also been proposed and highly commended in *diabetes*.* It appears to be harmless in this affection, and therefore may be used as a sweetening-material for coffee, tea, and other beverages; but there is no reason to believe that it exerts any control over the disease. The most important internal use of glycerin is as a harmless substance which has the power of disguising nauseous medicines. In this way it may be employed with castor oil, in emulsions of turpentine, in solutions of iron, and in various mixtures. It seems, as it were, to envelop the medicinal substances and prevent their acting on the palate. *Plasma* or *Glycerite of Starch* (*Glyceritum Amyli*, U.S.) is often used as a protective; *Glycerite of Yolk of Egg* (*Glyceritum Vitelli*, U.S.) is chiefly employed in making emulsions.

GLUSIDUM. Br.—GLUSIDE. SACCHARIN.†

Saccharin is a substance discovered by Dr. Fahlberg in 1879. Chemically it is an imide derived from the toluene of coal-tar. It occurs as a white powder composed of irregular crystals, very slightly

* For literature and discussion of point, see Ziemssen's *Encyclopedia*, vol. xvi.

† The present is probably as good as any other place in the book to notice a substance whose use in practical medicine depends upon its lack of medicinal properties. On account of its being a proprietary or patented drug it is not recognized by the U.S. Pharmacopœia.

soluble in water, readily soluble in glycerin, alcohol, and ether. Its watery solution has a distinctly acid reaction, and it forms salts. Its most remarkable property is its sweet taste, which is said to be three hundred times more intense than is that of sugar, so that if one grain of it be dissolved and neutralized in about ten pints of water its presence can still be recognized. A. Mosso and V. Aducco (*Archives Ital. de Biolog.*, 1886, vii.) find that frogs will live for months in a solution of saccharin rendered neutral with soda; also that the injection of a concentrated solution of saccharin into the cellular tissue has no influence on the batrachian. Six hundred grains given to a dog during ten days caused no alteration in the weight or general health of the animal. A careful study failed to detect any change in the urine as to the daily excretion of water, urea, hippuric acid, sulphuric acid, or phosphoric acid. The chlorides seemed to be somewhat increased. The saccharin escaped unchanged from the kidneys, rendering the urine very sweet, and having a notable effect in delaying its putrefaction. No saccharin could be found in either the milk or the saliva of a nursing woman to whom it was administered, and a dose of seventy-five grains caused no symptoms in man. Bruylants (*Bull. de l'Acad. de Méd. de Belgique*, 1888), however, found saccharin in the milk of a nursing woman, and was only able to recover a little over eighty per cent. from the urine; while Hedley (*Brit. Med. Journ.*, 1888, vol. i.) reports a case in which it seemed to be abundantly excreted with the saliva. Plugge has found, as the result of numerous experiments, that saccharin has a powerful influence in checking the action of ptyalin, pepsin, trypsin, and other allied ferments, and Sawitzki claims that it depresses proteid metabolism (*Sajous Annual*, 1891). Bruylants affirms that it does not check artificial gastric digestion, probably on account of the acidity of the solution, but that as little as one per cent. is enough to distinctly lessen the activity of pancreatin solutions. Nevertheless, I have frequently given saccharin freely without perceptible effect, and its general innocuousness is confirmed by Salkowski (*Virchow's Archiv*, cv. 46), by Bruylants, by Dreschfeld (*Birmingham Med. Journ.*, 1886, p. 409), by Levenstein (*Journ. Soc. of Chem.*, 1886), and by other clinicians. Mixed with sodium bicarbonate, two parts to three, saccharin becomes soluble, and is possessed of powerful antiseptic qualities. The chief value of saccharin in practical medicine is for the purpose of replacing sugar in *diabetes*, *obesity*, and other diseases in which sugar is contra-indicated, but the observations of Dr. James Little (*Trans. Royal Acad. of Med.*, Ireland, vi., 1888), that when freely given it is of great antiseptic value in the treatment of *ammoniacal urine*, from cystic, phosphatic, or other diseases producing retention or fermentation, are probably correct. It may be used freely as an article of diet, in the form of a solution in glycerin; for medical purposes it is sometimes administered in compressed pills: dose, five grains.

PETROLATUM, U.S.—Under the names of *vaseline*, *cosmoline*, etc., various yellowish, fat-like substances are sold which are obtained by distilling off the more volatile portions of American petroleum. The consistency of these substances depends upon the extent to which the distillation has been carried. The base of them all is paraffin. In the ordinary form they melt at about the temperature of 104°. *Liquid cosmoline* is a fluid substance obtained by a very incomplete distillation. *Petrolatum* of the United States Pharmacopœia is directed to have a specific gravity of 0.835 to 0.860. Cosmolines are insoluble in water, scarcely soluble in alcohol, but soluble in ether, chloroform, bisulphide of carbon, oil of turpentine, benzin, and fixed or volatile oils. By heat they should be completely volatilized without emitting acrid vapors. They do not become rancid, are absolutely free from irritating properties, and are much used as a basis for ointments and as emollient applications to the skin. *Petrolatum* has been taken and administered by Dr. Archer Randolph in doses of a drachm or more. He found it to have no general action on the system, but to act locally upon the mucous membrane of the alimentary canal much as it does on the skin, allaying irritation, and provoking soft fecal discharges.

POULTICES.—Under the head of Emollients I shall also speak of poultices, which are moist, soft, scarcely adhesive, perfectly bland plasters, used to a very great extent to combat superficial inflammation. Poultices are much more powerful agents than the true fatty emollients, and are correspondingly more capable of being abused: the results of such abuse will be spoken of directly. A poultice may, of course, be stimulating and irritant if made of such a substance as mustard; but the emollient or true poultice is prepared out of some bland material which is totally free from action upon the skin. I do not think that there is any difference whatever in the action of the various substances usually employed in the preparation of poultices, the latter depending for their remedial powers solely upon the warmth and water which they contain. Water, when pure and of a temperature approximating that of the body, is a sedative, checking all action, possibly by a direct influence, but probably by the merely mechanical acts of dilution of the pabulum and of separation of the germinal granules. It is also a relaxant, rendering all tissues soaked in it soft and yielding.

Poultices are sometimes applied in the early stages of phlegmonous and other superficial inflammations, for the purpose of checking the morbid action. Their influence is in such case simply one of sedation, and they are certainly not so efficient as the cold-water dressing. They are, however, especially useful in the advanced stages of inflammation, when suppuration has already commenced or is about to set in. Clinical experience has demonstrated that they now favor the formation of pus. It is hardly worth while to discuss how they do this, so long as the natural method in which pus is produced is a matter of dispute.

If, as Cohnheim believed, pus is composed solely or largely of outwandering white blood-corpuscles, it is evident that the relaxing influence of a warm poultice will greatly facilitate the escape of these bodies. Further, the poultice in the latter stages of a superficial phlegmon not only hastens the formation of pus in the inflammatory focus, but lessens irritation in the outlying parts by its sedative action, and so softens the tissues as to aid in the passage outwards and the discharge of the inflammatory products. When poulticing is too long persisted in, the part becomes pale or white, swollen, relaxed, and has a sodden look; the granulations of the ulcer or abscess are large, pale, and very flabby, and all the vital actions are below the normal point. It is possible that even death of a part might be brought about by continuous poulticing. Be this as it may, after the discharge of pus, whenever the parts put on the aspect just spoken of, the poultice should be removed and stimulating applications be substituted.

So far, the use of poultices to combat external inflammations has alone been spoken of; but clinical experience has demonstrated their value in internal inflammations, even when such deep-seated tissues as the lungs are affected. Their action in these cases is somewhat different from that which they exercise over superficial inflammations. According to the dictates of experience, they should be applied very hot, and be frequently renewed; very often, too, a small amount of mustard or of some similar stimulating material is added to them with advantage. As a result, these poultices act as gentle but deep-reaching counter-irritants, which in all likelihood affect not merely the blood-vessels of the skin, but also those of the subdermal tissue. When it is borne in mind that in all these cases the poultice is applied to a very large surface, it will be readily perceived that this counter-irritation is a powerful one. Thus, in *pleurisy*, or in *pneumonia*, the whole anterior or posterior surface of the chest is covered, or perhaps the whole chest is enveloped, by the jacket-poultice. In *peritonitis*, the poultice should be as large as the abdomen of the patient. In either of these cases the amount of blood drawn to the surface must be considerable. I cannot help surmising that the water of the poultice in some cases actually soaks through and exerts its direct sedative influence upon the affected tissue. The value of poultices in lung-diseases has seemed to me much greater in children, whose chest-walls are very thin, than in adults; and it is not illogical to believe that the difference may be dependent upon the inequality of the chest-walls.

The *jacket-poultice* should be made of thin flannel formed into a sort of double bag, so cut and shaped as to fit the individual, and secured in front with safety-pins and over the shoulders with tapes, or it may be fastened directly to an undershirt, a piece of oiled silk always being placed directly outside of the jacket. The jacket should be divided into two parts by a horizontal line of stitching, and be filled from one end. In order to prevent sagging of the contents, it is well,

after filling, to take a stitch here and there, in the manner of quilting. The effect of a jacket-poultice may be imperfectly attained by covering the patient with wool batting and oiled silk outside of this; but in fever patients the moisture from the surface and the heat of the body are serving to form a kind of fomentation.

Flaxseed meal is the most frequently used substance for making poultices, for which purpose the large amounts of oil and mucilage which it contains especially fit it. Ground *slippery elm* makes a very elegant demulcent, mucilaginous poultice. Ordinary mush from *Indian meal* affords a cheap and very serviceable material, and *bread and butter* makes a popular, very mild and unirritating, but expensive poultice. When a poultice is to be applied to affect internal organs, consequently has to be large and capable of holding the heat for a long time, the choice of material lies exclusively between flaxseed meal and Indian meal. The former of these is the more adhesive and the more manageable poultice; but popular belief, and I think for good reason, attributes to mush a superior power of retaining heat. In either case the poultice should be put on as hot as it can be borne, and should be covered by a large piece of silk oil-cloth, which aids in retaining not only the moisture, but also the heat. The interval of renewal should be short, and should be governed solely by the rapidity with which the applied poultice grows cold.

FAMILY XVI—DILUENTS.

A DILUENT is an indifferent substance which is absorbed and in its passage through the body simply dilutes the various fluids of the organism, as well as the excretions. The only diluent is water, which is given in various forms. Thus, the natural medicinal waters owe much of their value to the large quantity of water they contain. It is evident that when a quart of water more than usual is taken into the system, it must while it stays there lessen the concentration of the bodily liquids, and must finally in some way find an exit from the body. The increased excretion even of water means increased action in the eliminating glands; and the water passing out of the blood must always carry with it more or less of the soluble matters contained in the same, so that while the percentage of solid matter in the urine or in the sweat may be lessened by large potations of water, the actual amount eliminated is no doubt increased. Hence water acts not only as a diluent, but also as a depurant.

It is especially in regard to the urinary organs that water is employed medicinally, with three distinct possible objects. Thus, it may be used simply to aid the re-establishment of completely or partially suppressed renal secretion. In *acute Bright's disease* water has been found to be an efficient diuretic, increasing very remarkably the urinary excretion, relieving the irritation of the kidneys, and aiding the return to health. In these cases at least half a pint of water should be taken every two hours. I have tried it in chronic Bright's disease, and found it to work well in some cases; but in others, no increase of the urine taking place, the water accumulated in the system and added to the distress. Again, dilution of the urine is often important, as in *gonorrhœa*, or when there is a tendency to the formation of either *gravel* or *calculi*. Water is also used as a depurant in chronic disorders in which there is no organic disease, but an habitual torpor of the emunctories,—cases in which the liver is said to be torpid, and in which there is a foul tongue, habitual costiveness, and a scanty urine with a tendency to the formation of a lateritious deposit.* In these cases a couple of tumblerfuls of water upon rising will often produce a stool after breakfast, as well as increase the flow of urine. Very generally a mild saline may be advantageously added in small quantity to the water; and such natural mineral waters as those of Saratoga are especially beneficial.

* For experimental evidence that water in rabbits does increase the flow of bile, see Lawilski, *Centralbl. für Chir.*, 1877, p. 327.

FAMILY XVII-PROT

IN the present class are included those medicinal as external applications to exclude the athermal or other tissues. Sufficient has already importance of the exclusion of the air, under It is evident that the latter class of remedies act as protectives; but the class of Protective for the consideration of certain remedies which mechanical method in defending the skin against

First to be considered under the present is the adhesive plaster, used to protect the skin and raw surfaces. The adhesive plaster (*Emplastrum Resinæ*, U.S.) is used for mechanical purposes. It does, however, irritate the skin, and consequently is rarely employed where irritation is the object. Under the latter circumstances, the *Plumbi*, U.S.) or the soap plaster (*Emplastrum Saponis*, U.S.) is preferable. These substances are free from irritant properties, are slightly adhesive, and are scarcely used except to protect the skin from pressure or friction, as when *bed-sores* are threatened. It is also very inelastic, and so thick or hard as to lose their pliability. It is also very liable to become detached during the motions of the body. The *Isinglass Plaster*, or *Emplastrum Ichthyocolle*, U.S., is simply dampened, and is much used domestically.

COLLODIUM—COLLODIO

When any finely-divided ligneous body, if for a few minutes in a mixture of nitric acid 1.5 and concentrated sulphuric acid, and then washed, and dried, it gains about seventy per cent, and is converted into pyroxylin, or gun-cotton. The substitution of nitril (NO_2) for a portion of the hydrogen in a number of varieties of gun-cotton. The trinitrocellulose alone adapted for gunnery, is trinitrocellulose, the less highly nitrated variety, and is not fit for use. The official pyroxylin (*Pyroxylinum*, U.S.) is one of the varieties of gun-cotton, but is not soluble to any extent in ether.

Gun-cotton is a perfectly inert substance surface of the skin is concerned, and probably system when taken internally. It is not at all only use in medicine is in the manufacture of

is officinally prepared by dissolving two hundred grains of pyroxylin in a mixture of twelve and a half fluidounces of stronger ether and three and a half fluidounces of stronger alcohol. It is a colorless, slightly opalescent liquid, of a syrupy consistence, and smelling strongly of ether. By long standing it deposits a layer of fibrous matter, and becomes more transparent. This layer should be reincorporated, by agitation, before the collodion is used. When it is applied to the skin, and the menstrua are allowed to evaporate, collodion forms a colorless, transparent, flexible, and strongly contractile film, which adheres very closely, and cannot be readily removed by washing, motion of the part, or external mechanical force. As this coating is perfectly impervious to air and water, collodion is much used in surgery for various purposes. It is evident that care should be used in its application to abscesses and discharging wounds, lest it should prevent the discharge of pus. Small fresh wounds are often very advantageously dressed in the following manner, especially cuts on the fingers and about the head. If necessary, the hair should first be shaved off the part, and then a piece of coarse gauze or mosquito-netting, of suitable size and shape, should be laid so as to cover the wound and extend across each side from half an inch to an inch and a half, according to circumstances. One end should then be tightly fastened to the skin by repeated applications of the collodion with a camel's-hair brush. When the adhesion has become sufficiently firm, the gauze should be drawn so as to close the wound tightly, and while it is held in position the collodion should be applied all over it. As the collodion contracts during drying, the wound is more and more tightly closed and bound together.

The contraction of the collodion film is a great drawback to its use for certain purposes. This can be in great measure obviated and the film made more pliable by the addition of from eight to ten drops of castor oil to the ounce of the liquid. Under the name of *Flexible Collodion* (*Collodium Flexile*), the U.S. Pharmacopœia directs a preparation very similar to that just spoken of. It contains five per cent. of Canada turpentine, besides three per cent. of castor oil; and probably the stimulant effect of the terebinthinate will make itself apparent upon some susceptible skins. Whenever collodion is used simply as a protective, one of these modified preparations is much preferable to the pure article. Any principle which is soluble in a mixture of ether and alcohol may be added to collodion, and in this way medicinal substances may be applied to the external surfaces of the body. The films formed are often less firm and adhesive than those of the simple collodion.

Solution of Gutta-Percha (*Liquor Gutta-Perchæ*) is made by dissolving small pieces of gutta-percha in chloroform. When it is applied to the skin, a thin, elastic, adhesive film is left, which protects the parts from the air. It is an elegant preparation for use in *small cuts, abrasions, chapped lips*, and the little injuries which come within the province of domestic medicine rather than that of the professional art.

DIVISION II.—EXTRANEOUS REMEDIES.

THESE are drugs which are employed not to act directly upon the human system or upon any of its tissues, but upon some extraneous material or entity, either in the cavities of the body or upon its exterior. Thus, an antacid neutralizes acid in the stomach, or an anthelmintic kills the tapeworm in the intestines, or a disinfectant destroys poisonous emanations in the exterior world and thereby wards off disease.

FAMILY I.—ANTACIDS.

ANTACIDS are, strictly speaking, substances which are capable of neutralizing acid. The class, as here defined, contains those remedies which in medicine are used for the purpose of neutralizing an excess of acidity in the *primæ viæ*. They are almost solely employed in forms of *dyspepsia*. Without doubt, *cardialgia*, *gastric uneasiness*, "*heartburn*," and the rising of sour water in the mouth, are often the result of too much acid in the stomach, perhaps secreted by a perverted glandular action, but more probably in the great majority of cases formed by fermentative changes in the partially-digested food. As excessive acidity of the stomach causes gastric uneasiness and derangement, so will a similar condition of the intestinal canal cause pain and spasm and functional disturbance in the bowels. This is seen most frequently in infants, and is very often associated with a diarrhoea in which the passages have a green color, similar to that of spinach, and hence are sometimes spoken of as "*spinach-stools*." In *diarrhoea* of this character, as well as in *colic*, antacids are often of service by neutralizing the acid in the intestinal canal.

Clinical experience has demonstrated that dyspepsia is often permanently relieved by the use of alkalies when they are given steadily day after day, about twenty minutes after eating, for a long time. According to Dr. Thomas K. Chambers (*The Indigestions*, Am. ed., 1870, p. 67), this is dependent upon an effect pointed out by Claude Bernard, the augmentation of the acid gastric juice, and so of the normal peptic powers of the stomach. The same authority further says, "The test of benefit being derived from an alkali is the dose not requiring to be

increased as the patient goes on taking it, but, on the contrary, being diminished gradually, while relief from the recurrence of heartburn continues still to be experienced."

Sick headache is sometimes dependent upon gastric irritation produced by an excess of acid in the stomach. This true sick headache is generally to be distinguished from migraine by the early occurrence of the stomach-symptoms, either as heartburn, nausea, vomiting, or simple gastric distress, and by the fact that the pain comes on with an attack of blindness or of dizziness, and is not limited to any one spot, as the supraorbital or other neuralgic foci, but is felt all across the brows. In this form of cephalalgia antacids often afford relief.

Various substances which have already been discussed in this work are excellent antacids, most of them uniting this to other medicinal properties. Thus, when a stimulating antacid is desired, as is very often the case in sick headache, half a drachm of the *aromatic spirit of hartshorn* may be taken, well diluted with water. Again, when a laxative antacid is desired, a teaspoonful to a tablespoonful of *magnesia* may be exhibited. *Potassa* and its carbonates have already been dwelt upon with sufficient detail. They may be used as antacids; but, as they exert other powerful influences upon the system, they are, I think, not so generally useful as the soda preparations. Nevertheless, the *Solution of Potassa* (*Liquor Potassæ*, U.S.) is largely employed as an antacid. It is a colorless, water-like liquid, of a strong, acrid, alkaline taste, and is made by boiling a solution of the bicarbonate of potassium with lime. It contains only five and eight-tenths per cent. of the alkali, but acts upon animal and vegetable substances, and imparts a distinct soapy feel to the fingers when they are moistened with it and rubbed upon one another. It is capable, in overdose, of acting as an irritant poison. The dose is ten to twenty minims, well diluted.

SODIUM.

Unlike potassium, sodium and its salts have very little influence upon the higher animals. Frogs* are much more affected, it causing spinal convulsions, and also slowing, or even diastolic arrest, of the heart (Podocæpow, *Virchow's Archiv*, xxxiii. 507; Schönlein, *Arch. f. d. Ges. Physiol.*, xviii. 26). M. Laffont affirms that sodium primarily stimulates the frog's heart (*Compt.-Rend. Soc. Biolog.*, 1880, p. 282). Professor S. Ringer and Dr. H. Sainsbury find that the sodium salts are capable of arresting the cut-out frog's heart in diastole, the arrest being preceded by very little disturbance of rhythm: the amounts required were, however, so large that sodium salts can hardly be made to kill (*London Lancet*, 1882, ii. 736).

On the other hand, Grandeau (Robin's *Journal de l'Anatomie*, 1864) found that one hundred and seven grains of the carbonate of sodium

* Very many of the soda salts produce in the frog cataract. For a discussion of this, and literature on the subject, see Limbourg, *Archiv f. Exper. Path. u. Pharm.*, xxiv., 1886.

injected into the vein of a dog produced only a slight effect, and that thirty-five grains of the nitrate similar to that of Podocarpus caused only some convulsive movements in a rabbit (Virchow's Archiv, Bd. xxxv.), however, when injected directly into the blood in very large amounts the agony being very prolonged, and, when the convulsions being developed. Both Podocarpus and Podocarpus even the largest doses do not sensibly affect the temperature; and the latter observer further declares that it has no influence upon the nerve-centres, the peripheral nerves. If this be the case, however, it is difficult to explain the cause of death; and the earlier experiments of Podocarpus they do exert a very feeble action upon the peripheral muscles.

Upon the blood* the immediate influence of Podocarpus is slight, for Podocarpus asserts that one part of the blood does not affect either the physical properties of the muscles or the intensity of the ozone reaction; as the result of experiments made upon terrapins he concludes that sodium salts excite first the ganglia of the sympathetic and afterwards those of the vaso-motor nerves (Podocarpus 1886); and Dr. T. W. Mills (Canada Med. J. 1886) finds that the carbonate of sodium has a stimulating effect upon the heart of the fish. Curci (Lond. Med. J. 1886) also finds that the sodium salts increase the rate of the destruction of the oblongata, and believes that they affect the peripheral vaso-motor nerves. Experimenters have reached opposite conclusions in regard to the action of Podocarpus upon the frog's heart. (See Ringer, Brit. Med. Journ., Ex. Path. u. Pharm., xxiv., 1888.)

The effect of the continuous exhibition of Podocarpus in amounts of salt upon the human organism has been investigated by Dr. Münch (Archiv Vereins Gemein. 1863), and found to be very feeble. At first there was a diminution of excretion, and a corresponding gain in weight, but after a time the excretions increased, and the weight decreased. The variations in excretion affected the perspiration and the feces were also affected. The urine was rendered alkaline, but its solid ingredients were not affected.

Although a certain amount of the sodium salt

* Professor Kowalewsky records in the *Centralbl. f. Med.* an elaborate study of the effects of adding, either in solid form, or in solution, of potassium, sodium, lithium, and ammonium to the blood. He connects this influence with the effects of therapeutic doses of Podocarpus, and content myself with referring to the paper.

the higher animals, yet it is very doubtful whether an habitual excess of them has any decided effect upon nutrition. MM. Damourette and Hyades claim that the elimination of urea and uric acid (*Journ. de Thérap.*, 1880, 440) is markedly increased; but an examination of their experiments will show that this conclusion is not warranted by them, and in the researches of Dr. I. Mayer (*Zeitschr. f. Klin. Med.*, 1881, 82-95), of A. Ott (*Hoffmann u. Schwalbe's Jahresbericht*, 1883, 220), of C. Clair (*Centralb. Med. Wissensch.*, xxiv., 1888), and of L. Klemptner (*Dorpat Thesis*, 1889), neither the citrate, acetate, phosphate, or sulphate of sodium increased nitrogenous elimination. So that it must be considered as established that the sodium salts do not increase tissue waste.*

As Bidder and Schmidt (*Canstatt's Jahresbericht*, 1852) assert that the hydrochloric acid of the gastric juice is derived from chloride of sodium, and as Rabuteau (*L'Union Méd.*, t. xii. p. 186, 1871) found that in dogs with gastric fistula both the quantity and the acidity of the gastric juice are decidedly increased by the use of salt meat, it would appear probable that common salt acts as a tonic by increasing the digestive power. On the other hand, it is well known that physiologists are still disputing as to whether free hydrochloric acid exists at all in the gastric juice.† Further, it is certain that pepper or any similar condiment will, by its local action, increase the flow of gastric juice; and in Rabuteau's experiments the mere local irritation of the salt, or the difficult digestion of the preserved meat, may have given rise to the increased secretion by the stomach.

It appears to be well proved, clinically, that the alkaline salts of sodium given one to two hours before meals in full doses are of decided value in the treatment of chronic hepatic torpor, catarrhal jaundice, and especially of gall-stones or other affections associated with excessive viscosity of the biliary secretions. As the result, however, of an elaborate series of experiments made upon dogs with biliary fistula, J. Gliss (*Arch. Exper. Path. u. Therap.*, xxx., 1892) concludes that the alkalies given by the mouth do not increase the alkaliescence or amount of the bile. The caution necessary in applying such experiments to human medicine has been spoken of in an earlier chapter. Moreover, it was apparently proved by the experiments of Dr. S. W. Lewaschen that the sodium carbonate, sulphate, or phosphate, given to dogs with biliary fistula, increases very markedly the

* Hagendorf (*Dorpat Thesis*, 1890) found that the acids of the urine were not increased either by large doses of the citrate or bicarbonate of sodium; not much weight, it seems to me, ought to be attached to the experiments of Plouriez (*Compt.-Rend.*, xxv.), who believed that the daily use of one hundred and fifty grains of salt increased the number of red blood-corpuscles, and the amount of fibrin in his blood.

† See Bernard's *Physiologie Expérimentale*, t. II. p. 393, also *Philæ. Med. Times*, vol. v., and, for a discussion of the subject, Professor F. G. Smith's note to the American edition of *Marshall's Physiology*, p. 530; also *Louget's Physiologie*, Paris, 1881, t. i. p. 196.

liquidity of the bile by diminishing the power of the bile. Sodium salicylate acted similarly to, but much more powerfully than, the other salts.

SODA, U.S.—*Caustic Soda* is prepared by the action of *Liquor Sodæ*, and occurs in grayish-white fragments when exposed to the air; but, as the fluid absorbs water, soda in it is converted into an efflorescent carbonate, and at a time converted into a white powder. *Caustic Soda* is corrosive. *Liquor Sodæ, U.S.*—*Solution of Soda*—an alkaline liquid, containing about five per cent. of sodium carbonate, having the specific gravity 1.059. It is made by dissolving lime upon a solution of carbonate of sodium.

SODII CARBONAS, U.S.—*Sodium Carbonate*, anhydrous, which rapidly effloresces on exposure to the air, is a white powder. The taste and reaction are alkaline. It is very soluble in water, insoluble in the air. The salts from which it is manufactured are common. As it occurs in commerce, sodium carbonate is of the ordinary use. When sodium carbonate is heated, carbon dioxide is driven off, and the official *Dried Sodium Carbonate, U.S.* is left. This may be given in the form of *Sodium Bicarbonate* (*Sodii Bicarbonas Venalis*), a white powder, containing variable amounts of soda not combined with carbonic acid. Pure *Sodium Bicarbonate* (*Sodii Bicarbonas Purus*) always be selected for internal use. The antacid action is ten to twenty grains.

THERAPEUTICS.—The fact that soda, in moderate doses, has a depressing action, and indeed very little, if any, on the general system, renders it preferable to potash in the treatment of the primæ viæ. It is *par excellence* the alkali of choice. On the other hand, the circumstance clearly established by experiment (Urinary and Renal Diseases, Amer. ed., 1869) that it is as powerful as a solvent of uric acid than its property, believed to belong in a much greater degree to potash, of preventing the formation of uric acid, makes its value in *uric acid gravel* or *uric acid diathesis*, especially desirable simply to render the urine alkaline, and to avoid depressing the system generally, so that on all grounds at least, seem preferable.

• E. Dufourt (*Archiv. d. Méd. Expér. Anat. Path.*, 1869) found that the bicarbonate of sodium upon dogs, found that there was an increase both of the glycogen and of the sugar of the liver.

Sodii Acetas, U.S.—*Sodium Acetate* is a white, slowly efflorescent salt, which occurs in long prisms of a sharp, bitterish taste. It has been supposed to have the same remedial powers as potassium acetate; but this is certainly a mistake. It is rarely, if ever, used in medicine. *Sodium Nitrate*, although official, is not used as a therapeutic agent.

CALCIUM.

The calcium salts are contained in large quantity in the human organism, mostly, it is true, in insoluble and, consequently, comparatively inert forms. It is highly probable, however, that the soluble salts have close relation with the general nutrition, since Dr. W. H. Howell and Miss E. Cooke (*Journ. Physiol.*, xiv., 1893) have proved that the inorganic salts of the blood, milk, gastric juice, etc., are able to keep the isolated frog's heart beating with force and regularity for many hours without other food, whilst according to the experiments of Ringer, among these salts those of lime are especially important. Further, it seems to be demonstrated that small doses of soluble calcium salts increase the energy of the heart's action, as the experiments of Ringer (*Journ. Physiol.*, v., vii.) have been confirmed by Mickwitz and also by Binet. Binet (*Revue Méd. d. l. Suisse Romande*, 1892) states, however, that though the cardiac arrest usually takes place in systole in calcium salt poisoning, yet if the salt have come directly in contact with the heart in concentrated form there is paralytic arrest (diastolic). Upon the nerve-centres the calcium salts, when in sufficient amount, according to Binet, act as a paralyzant, affecting especially the motor centres of the cord and the cerebral cortex.

CALX—LIME. U.S.

The therapeutic properties of slaked lime are dependent chiefly upon its alkalinity and its astringency. It does not possess the latter property in an eminent degree, yet its preparations, when properly diluted, whiten and lessen the secretion of mucous membranes to which they are applied. It also appears to have, as it were, a sedative influence upon mucous membranes, lessening their irritability. *Caustic or unslaked lime* is a powerful caustic, but, except in the form of Vienna paste, is rarely if ever used as such. It is more soluble in cold than in hot water. At 60° F. it requires about seven hundred times its weight of the liquid to dissolve it. It is much more soluble in syrup than in pure water.

Liquor Calcis, U.S.—*Solution of Lime*.—*Lime-water* is a colorless liquid, having the sp. gr. 1.0015, and containing about 0.15 per cent. of lime. It has an alkaline taste, and is nearly destitute of irritant properties. On exposure to the air it becomes turbid, or forms a crust upon the surface, or deposits a precipitate, owing to the absorption of carbonic acid from the air and the conversion of the lime into a carbonate.

Twenty minims of *syrup of lime* (*Syrupus* Ounce of lime-water.

Even soluble preparations of lime have amount, any distinct influence upon the hum been shown by Carl Franke (*Wurzburg The venous injection of very large amounts has Concentrated solutions of lime seem, however, upon the voluntary and involuntary muscles of to Ringer* (*New York Med. Rec.*, xxxi.) and *News*, Sept. 1886), act, at least at first, as stim Franke, finally paralyze muscular contractil mucous membranes, the solution of lime, if no to have a detergent and distinctly sedative inf

THERAPEUTICS.—Lime-water is used inter effects upon the *primæ viæ*. In *vomiting*, from acute gastritis, equal parts of lime-water and simple, and much-used remedy. If the vom food should be inhibited, and one or two table given every half-hour,—the quantity, as well being increased as the stomach is able to bear put in milk prevents the formation of dense with advantage to that fluid when used as food with weak digestion. As an alkaline astric useful in *diarrhœa* in doses of one to two fluid

Externally, lime-water has been used as a cases, especially in *tinea capitis*: it is also app to have a very marked influence in lessening When mixed with an equal bulk of linseed *Calcis*, U.S.), lime-water is a favorite applicati thick, soapy liquid which is formed is someti Oil, from the name of the iron-works at w first made.

Lime-water has the power of dissolving m brane, and has therefore been introduced as membranous croup and in *diphtheria*. It is so the patient to inhale the vapors of slaking li is to pulverize lime-water by means of an atom upon the back of the fauces while the patient application should be made every two or thr of sufficient age to allow of its being thorou able.

CALCIUM CARBONATE

Chalk is the native, friable calcium carb solid, of an insipid, earthy taste, insoluble f with effervescence, in dilute muriatic acid. *Prepared Chalk* is chalk freed from impurities

tion, and elutriation; a white, perfectly smooth powder. *Calci Carbonas Præcipitatus*, U.S.—*Precipitated Calcium Carbonate* is a white powder, free from grittiness, which is made by precipitating calcium chloride with sodium carbonate.

THERAPEUTICS.—Calcium carbonate in its different forms is used internally as an antacid and a very mild astringent. As none of the salts which it forms are purgative, it, with the other preparations of lime, is the best antacid when *diarrhæa* is present. The crude chalk should never be used, but the other preparations are probably of equal value. Some practitioners claim, however, that the oyster-shell is more acceptable to delicate stomachs, on account of the animal matter which it contains; and, under the name of *Castillon's Powder*, a mixture of salep, tragacanth, sago, of each three parts, prepared oyster-shell one part, and cochineal sufficient to color it, has been much used in obstinate summer diarrhæas. A drachm of this is boiled in a pint of milk, and the decoction taken as food *ad libitum*. The dose of carbonate of calcium is twenty grains to a drachm. *Chalk Mixture* (*Mistura Cretæ*, U.S.) is generally preferred to the powder. It contains thirty grains of the chalk to the ounce, and is given in doses of one to two tablespoonfuls. It is often combined with laudanum or paregoric and tincture of kino or catechu.

Externally, prepared chalk and precipitated carbonate of calcium are used as desiccants and protective applications to *ulcers* and *chronic burns*, also in *excessive sweating* of the feet, and in *intertrigo* and other affections of the skin.

CALCIUM HALOID SALTS.—Professor Germain Sée (*Bull. de l'Acad. Méd.*, 1892) has called attention to the value in practical therapeutics of the calcium bromide and iodide, claiming especially that they improve digestion, and that they are absorbed and eliminated with rapidity. The *Calcium Bromide* contains eighty per cent. of bromine (against the seventy-seven and a half per cent. of the sodium bromide, the sixty-seven per cent. of the potassium bromide, and the sixty-five per cent. of the strontium bromide), and ought to be useful in *epilepsy*. The calcium bromide is a very deliquescent soluble salt, which must be given in solution. The dose is probably that of the alkaline bromides. The *Calcium Iodide* contains eighty-six per cent. of iodine, against the eighty-three per cent. of the sodium iodide, the seventy-six per cent. of the potassium iodide, and the seventy-four per cent. of the strontium iodide. The *Calcium Chloride* is strongly recommended by Professor Sée in the treatment of *gastric catarrh* and fermentative *lyspepsia*. Dose, fifteen to seventy-five grains a day.

FAMILY II.—ANTHELMINTICS

These are medicines which kill or cause the expulsion of worms. They are sometimes divided into *vermifuges*, those which expel; but there is no real division. It is of much greater importance to know the relations between these drugs and the different species of worms. Clinical experience has demonstrated that an anthelmintic which is effective against one form of intestinal worm may be ineffective against another species. Therapeutically considered, the anthelmintics are divided into the *Tapeworms* (*Tæniæ*), the *Round-worms* (*Leishmaniasis*) (*Ascarides*). The last of these differ from the first in that they can be attacked solely by enemata.

It is obvious that the value of an anthelmintic depends upon its power of poisoning the articulate, and not upon its harmlessness as regards the patient. Thus, it is the irritant qualities that renders the infusion of quinine effective against seat-worms, while carbolic acid, though very powerful, can be used against the same parasite, since it has not destroyed, the life of the patient when used.

There are certain general rules which govern the administration of anthelmintics, and which should not be lost sight of. They may be summed up as follows: Let the alimentary canal be empty, so that the drug may act with the greatest effect. For this reason, anthelmintics are best administered on an empty stomach; and in obstinate cases the patient should be fasted during dinner-time.

If the drug be not itself a purgative, from its administration a brisk cathartic should be given. A small dose of calomel may be combined with the anthelmintic; induced by the latter drug seems to be an effective method of attacking the entozoa.

SPIGELIA—PINKROOT

The root of *Spigelia Marilandica*, an herb growing in the Southern and Southwestern United States, has a knotty head, with numerous fine, crooked, roots. The odor is faint and peculiar; the taste sweetish. It contains, according to the analyses of M. F. F. F., tannic acid, fixed and volatile oils, resin, and

body; but exactly upon what its virtues depend has not been determined.

PHYSIOLOGICAL ACTION.—According to the investigation of Dr. H. A. Hare (*Medical News*, March 12, 1887), *spigelia* produces in the frog exophthalmia, excessive muscular weakness, loss of reflex activity, and slowing of the heart, with at first increase of power of the systolic contractions but afterwards arrest in a condition of semi-diastole. In the dog the drug produces hurried respiratory movements, retching, wide dilatation of the pupil, internal strabismus, marked exophthalmia, muscular weakness and loss of co-ordination, and at last sleep, passing into coma and death from failure of respiration. The loss of muscular power and of reflex activity is spinal, both motor and sensory nerve-trunks escaping. Moderate doses produce in the warm-blooded animals slowing of the pulse, with fall of the arterial pressure. As the pulse is not affected after section of the vagi, the slowing is probably the result of central inhibitory stimulation. The fall of arterial pressure seems to be chiefly the result of an action upon the heart, since asphyxia causes at such times an immediate rise in the pressure,—i.e., vaso-motor spasm. The observations of Drs. Hodge Thompson (*Inaug. Diss.*, quoted by Eberle), Eberle (*Materia Medica and Therapeutics*, vol. i.), and Spalsburg (*Boston Med. and Surg. Journ.*, 1885) have shown that in overdose it causes in man acceleration of the pulse, dilatation of the pupils, heat and dryness of the skin, flushing and a swollen appearance of the face, with, in Eberle's cases, talkative delirium. Two fatal cases* of poisoning by it are said to have been recorded.

THERAPEUTICS.—*Spigelia* is a most efficient remedy in cases of the round-worm, and is, when given within the bounds of moderation, entirely safe. It appears to narcotize the worm, and requires the use of a brisk cathartic. The *fluid extract* (*Extractum Spigeliæ Fluidum*, U.S.) is efficient in doses of two fluidrachms. A better preparation is the *Fluid Extract of Spigelia and Senna* (*Extractum Spigeliæ et Sennæ Fluidum*, U.S. 1870), which is much liked by children on account of its agreeable taste. The dose for an adult is fʒss; for a child two years old, fʒss to fʒi, repeated every four hours until it purges.

AZEDARACH, the bark of the root of *Melia Azedarach*, or Pride of China, is used in the South as a remedy for the round-worm. It is said to possess poisonous properties similar to those of *spigelia*, yet it is affirmed that animals and children eat its fruit with impunity. It is usually given in decoction (ʒii to Ojss, boiled to a pint), the dose being for a child a tablespoonful every two or three hours until the bowels are affected.

CHENOPodium, U.S., or *Wormseed*, is the fruit of *Chenopodium*

* These cases appear to have been indefinitely copied, and are of doubtful authenticity.

anthelminticum, or Jerusalem Oak, a rank about waste places in the suburbs of towns, consists of minute, globular, light-brown seed head, of a nauseous odor and a pungent taste which they contain in large quantity. *Worms* (U.S.) is of a light-yellow color, becoming dark of a peculiar powerful odor and a hot burn used in *hysteria*, but is now employed only as the *lumbricus*, and more rarely the *tape worm*. ten drops of it on sugar may be given to a child at breakfast, dinner, and supper, for two days,

Cusso, U.S., or *Kouso*, is the female *abyssinica*, a tree, native of Abyssinia. greenish-yellow clusters, of a fragrant bal which in a little while is acrid and disagreeable, containing a volatile oil, tannic acid, and a resin, *Kouso* by Pavoni. This is crystalline, white or yellow, freely so in alcohol, and was shown in the *Year-Book*, 1868, p. 476) to be the active principle. It yields about three per cent. of it. *Brayera* against the *tape worm*, and even in large doses, is more convenient to the patient than some nausea, and cramp of the bowels. It is generally not necessary to combine it with a purgative, and the worm is discharged in watery passages. A half-ounce of the powder suspended in water in the morning, with the addition of ten or from twenty to forty grains of kouassin, will be substituted for the crude drug. The *fluidum*, U.S.) is also efficient in doses of 10 to 20 minims. It should be exercised in giving brayera to children. It is stated that it has produced abortion.

SANTONICA—SANTONI

Lerant Wormseed consists of the unexpanded flower of *Artemisia pauciflora*, a composite of Northern Asia. It consists of pale, greenish-brown, anthers, and tubular flowers, of a very strong aromatic bitter, disagreeable taste. It contains volat

* In the *Maryland Med. Journ.*, vol. iv. p. 20, Prof. J. H. H. which death was attributed to the taking of an ounce of santonica in doses. The patient was found in bed unconscious, with vomiting, after some hours became sensible, relapsed an hour later, again roused, and while playing cards became aphasic, deaf to other sounds, and finally died with hemiplegic apoplexy. It was not the direct immediate cause of all these symptoms.

a crystalline principle, *Santonin* (*Santoninum*, U.S.), or *Santoninic Acid*, which occurs in colorless, pearly, four-sided, orthorhombic tables, soluble in from four thousand to five thousand parts of cold and two hundred and fifty parts of boiling water, freely soluble in alcohol and chloroform, moderately so in cold ether; insoluble, or nearly so, in glycerin. It has a neutral reaction, but unites with alkalies to form salts, and hence is freely soluble in alkaline solutions. When slowly heated, it sublimes unchanged, at from 165° to 175° C. When rapidly heated, it is converted into a brownish-red oil, which becomes carmine-red upon the addition of caustic potash. On exposure to sunlight, or, more slowly, even in the ordinary daylight, the colorless crystals of santonin acquire a golden-yellow tint. If this change be a chemical and not a mechanical one, the alteration must be very slight, since, according to Krauss, the yellow crystals conduct themselves in their chemical relations precisely as do the colorless crystals, and are precipitated, by the addition of acid to their alkaline solutions, as colorless crystals.

PHYSIOLOGICAL ACTION.—Santonin is said to have been first introduced into medical practice in 1830, by Dr. Alma, by whom and by Dr. Kahler it was simultaneously discovered. It is at present used almost solely on account of its poisonous action upon entozoa, but certainly has a very great influence upon man and the higher animals. When it is given to dogs or other domestic animals in large doses it causes accelerated breathing, slowing of the pulse, universal trembling, cramps, free salivation, unconsciousness, convulsions, dilated pupila, and death. (See experiments of Manns, *Das Santonin*, Marburg, 1851; of Rose, *Virchow's Archiv*, Bd. xvi., 1859; of T. Krauss, *Inaug. Diss.*, Tübingen, 1869; and of Fröhner, *Monatshefte f. Thierheilk.*, Bd. iv., 1893.) After death the lesions are not absolutely constant, but hyperæmia of the nerve-centres and congestion of the lungs and heart are nearly always present. According to Rose, dogs will recover after doses of from thirty to sixty grains, although five to six grains will produce very decided symptoms; and according to Krauss, thirty grains are required to kill a rabbit, even when the drug is dissolved in chloroform and given subcutaneously. Fröhner has noted that the drug produces in many domestic animals polyuria, sometimes strangury, and very commonly pronounced sexual excitement; and suggests its use in man as an aphrodisiac.

The symptoms caused by large doses of santonin in man are closely similar to those which it produces in the lower animals. There are several fatal cases of poisoning by it on record. A child five years old was killed in half an hour by an unknown quantity (*Pharm. Journ. and Trans.*, viii. 996), and one six or seven years old is said to have been destroyed by six grains of the acid, after suffering from hæmaturia*

* This is probably a mistaken observation, the urine being only blood-colored, and not containing blood (see p. 947).

(*Bull. Thérap.*, lxxiv. 362): four grains produced very serious symptoms in a child four years old (*Pharm. Journ. and Trans.*, ix. 696). In Dr. Grimm's case (*Schweizer Zeitschrift für Med., Chir., und Geburtshilfe*, 1852, p. 493), a rather feeble child, five years old, took two one-grain doses of santonin, and was seized with convulsive tremblings, which increased in severity until they became severe convulsions, which were accompanied by unconsciousness, trismus, pallor of the face, cold sweats, dilated pupils, and rapid pulse and respiration. Thirteen or fourteen hours after the ingestion of the poison, while the patient lay on her back, quiet, unconscious, with moderately-dilated pupils and a slow, feeble pulse, death occurred suddenly. No post-mortem was allowed. The santonin is stated to have been chemically pure and to have been used in other cases with its usual results. Nine-tenths of a grain of santonin are said to have caused complete unconsciousness in a child five years old (*Schmidt's Jahrb.*, Bd. cci. p. 128). Six grains of santonin caused in a child five years old epileptiform convulsions and death in thirty-five minutes (Dr. W. J. Kilner, *St. Thomas's Hospital Reports*, vol. x.). One grain and a half produced in a child three and a half years old symptoms of the utmost severity, not reaching their maximum until two days after the ingestion of the poison (*Therap. Gaz.*, iii. 210: for other cases, see Dr. C. Beville, *Therap. Gaz.*, iii. 428). In one case complete blindness persisted for nearly a week. Great pallor of surface, with a blue color around the eyes or involving the whole countenance, has been generally an early symptom; vomiting has not rarely been present, and sometimes has been accompanied by colicky pains. Besides these manifestations, giddiness, mental apathy or stupor, great coldness of the surface, profuse sweating, trembling, mydriasis, and finally loss of consciousness, with convulsions, often violent and accompanied by opisthotonos and emprosthotonos, and failure of respiration, are the usual phenomena of santonin-poisoning. The circulation seems to be very little affected (case, *Arch. für Exper. Path. und Pharm.*, vi. 302).

A very curious symptom caused by santonin, even when in doses which can scarcely be called toxic, is xanthopsia, or "yellow-seeing," as the Germans term it. It was, I believe, first noticed by Calloud, and has since been spoken of by almost every writer upon the drug. Usually it consists of a very deep yellow tint imparted to the landscape and to every object looked at, an effect perhaps most comparable to that of looking through yellow glass; sometimes this yellow is replaced by green; and Heydloff states that he has seen patients in whom the tint was red, and others in whom it was blue. Dr. Edm. Rose has published exceedingly elaborate papers upon this chromopsia; but, as the matter is of interest to the physicist and student of optics rather than to the physician, I content myself with a reference to his memoirs (*Virchow's Archiv.*, xvi. 233; xviii. 15; xix. 522; xx. 245; xxviii. 30). Santonin is probably in a more or less altered condition by the kid-

neys, and thus gives rise to a very characteristic symptom which has not as yet been spoken of,—namely, discoloration of the urine. The new color is a very marked yellow, which has at first an orange tint, but after very large doses becomes saffron-like, or sometimes even a purplish red, which has given origin to the idea that blood was present. According to Manna, the addition of an alkali to the yellow urine causes it to become red. The exact nature of the eliminated principle has not been determined: it is, however, probably the result of an oxidation of the santonin, as is believed by Kletzinsky, who asserts that the drug receives in the system six atoms of oxygen.*

The results of the ingestion of large doses of santonin show that it has a very powerful action on the organism; but as to what portions of the latter are especially affected we have no information. Rose believes that the chromopsia is due to a peculiar action of the drug upon the nerve-centres; but more probably it is simply the result of a very faint staining of the humors and other parts of the eye by the drug, and is analogous to the similar phenomenon sometimes seen in jaundice. Like very many other substances which escape through the kidneys, santonin increases the flow of urine, and, according to Dr. Farquharson (*Brit. Med. Journ.*, 1872), it increases slightly the elimination of urea.

THERAPEUTICS.—Dr. D. Dyce Brown (*Brit. and For. Med.-Chir. Rev.*, April, 1871), having noticed that a blind man to whom he was giving santonin for worms recovered to an extraordinary degree his vision, has recommended it in cases of loss of optic nerve power, and Dr. Ogston has used it with more or less complete success in a number of cases. Although Dr. Brown had apparently no knowledge of it, yet many years before his experience M. Guépin and M. Martin recommended the drug in *amaurosis* (*Ann. de Thérap.*, 1862). M. Guépin believes it to be especially useful in *amaurosis* following *choroiditis* and *iritis*. Whether the use of santonin in diseases of the eye will ever amount to anything, cannot at present be told. The same may be said of its use in *epilepsy* (*Brit. Med. Journ.*, 1876, ii. 787).

As the result of experiments made with santonin in saline solution and also dissolved with oil, Von Schröder (*Arch. f. Exper. Path. und Pharm.*, xix. 304) affirms that it is very feebly toxic to the *ascarides*, and that it acts as a vermifuge simply by annoying the worm and causing it to loose its hold and allow itself to be swept out by purgatives. This is, however, exceedingly doubtful. Santonin undergoes in the alimentary canal slow conversion into a soluble santoninate. Von Schröder's experiments, even if they be absolutely accurate, do not

* Chrysophanic acid produces a discoloration of the urine similar to that caused by santonin. According to Hoppe-Seyler, the cause of the coloration can readily be distinguished by adding caustic soda to the urine, and then shaking up with amylic alcohol, when, if the coloration proceeds from santonin, the urine is decolorized, while, if it be due to chrysophanic acid, the alcohol takes up only traces of the coloring-matter.

prove that the soluble santoninate of sodium brought in contact with the worm does not do so. The opinion of helminthologists is that santonin is not so. Its method of action may be, it is certainly not so. Round or lumbricoid worm, but it should either be followed in about two or three hours by a brisk purgation of calomel and santonin has been much used. Bergey claims that santonin has especial value in the treatment of the menses if given in full dose at the time of the menses. In acute suppression of the menses (*Amer. J. Med.*, 1877, ii. 857).

TOXICOLOGY.—It has been denied that the evil results which have followed the mixture of strychnine with the drug. The opinion is that in one or more cases death has been caused by being mixed with santonin, or else sold in this way (1877, ii. 857), through the carelessness of a pharmacist. In an extended examination (*Jahresbericht*, 1877, xv.), found that the santonin of the shops is not pure, but how strychnine could be mixed with it is a gross carelessness. Moreover, the symptoms produced in alleged poisoning by santonin are caused by strychnine, and are in close accord with those induced in the lower animals. Finally, in seven of which are collected by Krauss, the drug was found to be pure. Under these circumstances to deny the poisonous properties of santonin is to deny the poisonous properties of strychnine. The hardness and insolubility of the crystals of santonin, of poisoning by santonin, after evacuation of the bowels must at present be entirely tentative. One case was saved by artificial respiration (*Arch. für Exp. Med.*, 1877, 300); but Professor Binz (*Ibid.*) has found that morphia, and artificial respiration alike used with the poison appeared to be of service.

ADMINISTRATION.—Santonin is best administered in the form of *Santonini*, U.S., one-half grain each.* The adult is two to four grains; for a child two to four one-half grain. Very alarming symptoms have followed one-grain doses exhibited within three hours (Grimm); in a child two and a half years of age came very near causing death (Dr. Berg, *respondenzblatt*, 1862), and in the fatal case two grains were taken by a child five years of age. Santonin is hardly a safe remedy in any effect.

* Lozenges made with unbroken crystals and proper sugar, the official preparation.

any size is given, it should not be repeated in less than eight hours, and the last dose should be accompanied by a purgative amount of calomel.

The soluble *sodium santoninate* is much more dangerous and less efficient than *santonin*: the object is to get as much of the remedy as possible in contact with the worm, and, as to do this a slow, not a rapid, absorption is necessary, the insolubility of *santonin* is an advantage.

ASPIDIUM, U.S.—*Filix Mas*, or *Male Fern*, is the rhizome of *Aspidium filix mas*, or male fern of Europe. Under the name of *Aspidium* the present U.S. Pharmacopœia recognizes both it and the rhizome of the indigenous *A. marginale*. The rhizome, when perfect, is six to twelve inches long, and covered with large, brown, imbricated scales. Its taste is bitter and astringent. It contains an amorphous acid, *filicic*, which, according to the experiments of E. Poulsen (*Archiv f. Exper. Pathol.*, xxix., 1891), is a very active substance, causing, in the frog, at first excitement and then paralysis of the central nervous system, and finally paralyzing the heart and exerting a marked influence upon the muscles: producing in warm-blooded animals violent diarrhœa, with a general paralysis, due to depression of the spinal centres, and finally cardiac palsy. Professor Robert (*Therap. Monatsch.*, 1893), however, as the result of his experiments, believes that the vermifuge principles of male fern do not depend solely or even chiefly upon *filicic* acid, but upon the ethereal oil. However this may be, it is certain that the official *oleoresin* (*Oleoresina Aspidii*, U.S.) thoroughly represents the crude drug. It is a dark, thick liquid, of a bitter, nauseous, slightly acid taste. In overdose it is a violent poison, producing excessive vomiting and purging, with general weakness, tremors, cramps in the extremities, increased reflexes, amaurosis, and finally, in some cases, violent tetanic convulsions, with opisthotonos, stupor deepening into coma, and collapse. Eight grammes of the extract have caused death in a child about three years old; six drachms of the oleoresin have several times proved fatal in the adult (*Therap. Monatsch.*, iii., 1889; *München. Med. Wochen.*, xxxvii., 1890; *Lancet*, 1882; *Deutsch. Med. Wochen.*, xvii., 1891): in Professor Paltauf's case the fatal result is said to have been due to four and a half grammes (*Schmidt's Jahrb.*, Bd. cexxxvi.). In a case reported by Dr. Bayer (*Prag. Med. Woch.*, xiii., 1888), there was blindness of one eye after recovery of consciousness. The lesions to be found after death are probably those noted by Professor Frohner in the lower animals,—namely, hemorrhagic gastro-enteritis and cystitis, with violent parenchymatous nephritis (*Monatsch. Prakt. Thierheilk.*, 1890). According to the experiments of Quirll (quoted by Eich), the fatal result is partially due to the violent irritation of the gastro-intestinal tract, and partly the result of an influence upon the central nervous system.

THERAPEUTICS.—Male fern is employed almost exclusively against the tapeworm. In its administration it is necessary to regard strictly

the general rules applying with greater or less force to emetics, but which are especially imperative against the tapeworm. The patient should fast for one day, and the following morning (f3i) of the oleoresin, fasting, and repeating. At noon the patient may eat freely, and in the evening a cathartic should be given. In overdoses, the oleoresin acts as a violent poison, producing excessive gastroenteritis, pronounced general weakness, giddiness, stupor, tremors, cramps in the extremities, amaurosis,

PEPO, U.S.—Pumpkin Seeds.—The seeds are a most valuable remedy in cases of tapeworm, more efficient than the male fern, and perfectly safe. The seeds may be beaten up with sugar into a mass, or into an emulsion, and be taken fasting in the morning, having fasted the previous day. Some hours after a brisk purge should be given. Mr. I. G. Wiegman's principle is a resin, which he has found efficacious.

TURPENTINE, in doses of half a fluidounce, is efficient both of tapeworm and of round-worm. It produces unpleasant effects, and should be avoided. Other remedies have been used without success, and turpentine should be given in combination with twice the dose of castor oil.

GRANATUM, U.S.—Pomegranate Rind.—The root is efficient, though very unpalatable, and a decoction of the fresh root (3ii to Oj) is to be taken in three doses, an hour apart, before meals. The chemist C. Tanret has isolated from the bark a principle (Thérap., xcvi. 316), of which two, *pelletierine* and *granatine*, have been found by Dujardin-Beaumetz to be active. That in sufficient amount they act in the same manner on animals as does curare, causing paralysis of the voluntary muscles, affecting sensation or muscular contractility, and that a salt of the alkaloids is said to be 4.6 grains. The statement that the paralysis is peripheral, and that the peripheral nerves themselves are affected (*La Spérimentale*), is not confirmed. *Pelletierine* as an anthelmintic has been confirmed. It has by some been used in doses of twenty grains, but also has been employed it successfully in Ménière's disease. Hypodermic injections of six grains produce muscular weakness, with great retinal congestion. Doses of 15 grains cause in the adult pronounced muscular weakness, almost to general paralysis, and a number of cases in which it has produced in infants symptoms

its employment in patients of that class. (See *Bull. de Thérap.*, lxxviii., lxxix., lxxx., cxi., July, 1886; also *University Med. Magazine*, i. 639.) M. Galezowski has used pelletierine in paralysis of the third and sixth pairs of nerves with asserted good results (*Brit. Med. Journ.*, Nov. 28, 1885).

THYMOL, U.S., has been used by Dr. Neuma Campi (*Il Raccoglitore Medico*, abstracted in *Buffalo Med. Journ.*, Oct. 1886) for the destruction of tapeworm: he gives half an ounce of castor oil in the evening, in the morning two drachms of thymol divided into twelve doses, one to be taken every quarter of an hour, and twenty minutes after the last dose of thymol another dose of castor oil. It is also stated that Federici has found the remedy very effective against the *Ancylostoma duodenale*.

MUCUNA.—*Cowhage*.—The sharp, rigid hairs of the pods of *Mucuna pruriens*, an East India plant, were formerly used in cases of the round-worm. They are believed to kill the worm by piercing it. The pods are dipped into molasses, the hairs scraped off, and a tablespoonful of the thick mass given to an adult—a teaspoonful to a child—morning and evening, for three days, after which a brisk purge is administered.

KAMALA, U.S.—*Kamala*.—The glands and hairs from the capsules of *Mallotus philippinensis*, a plant cultivated in India as a dye-stuff. It is said to be an efficient parasiticide in cases of tapeworm. It is an orange-red, very inflammable, granular powder, mixing with water with some difficulty, and containing traces of a volatile oil and coloring resinoids, to one of which Dr. Anderson has given the name of *Rottlerin*. Kamala, in full doses, is actively purgative, indeed drastic, and sometimes causes also nausea and vomiting. It imparts its virtues to alcohol, and hence may be exhibited in the form of tincture. The dose of the powder is from one to two drachms suspended in syrup, given in the morning, and repeated in eight or ten hours if it do not purge.

FAMILY III—DIGESTANTS.

In this family are associated a few remedies which are used to aid the alimentary canal in dissolving the various articles of food.

PEPSIN.

As every one knows, there is secreted by the gastric glands a peculiar albuminous body, which has the power not only of coagulating albumen, but also, with the aid of acidulated water, of redissolving it. To this principle the name of pepsin has long been given. A discussion of its nature and properties would be more in place in a work on physiology than in one on therapeutics. The U.S. Pharmacopœia now recognizes a stronger and weaker pepsin. *Pepsinum*, U.S., or *pepsin*, is required by the Pharmacopœia to be able to digest three thousand times its weight of freshly-coagulated egg albumen. *Pepsinum Saccharatum*, U.S., or *Saccharated pepsin*, contains ninety per cent. of sugar of milk, and should be able to digest three hundred times its weight of egg albumen.

The dried stomach of calves has been used since time immemorial for the purpose of coagulating milk, by housewives, with whom it is customary to place the dried viscus in wine, and to call the liquid thus formed, as well as the prepared stomach, *rennet*. It is stated by Dr. James Gray (*Edinb. Med. Journ.*, Jan. 1853) that rennet-wine should be of such strength that one teaspoonful of it will coagulate a pint of milk. Rennet is said to have been long used in England as a domestic remedy in dyspepsia (*Med. Times and Gaz.*, April, 1857). In South America the inner coat of the gizzard of the ostrich is stated to be put to a similar use (E. S. Wayne, *American Journal of Pharmacy*, 1868); and in our own country the dried gizzards of chickens and turkeys are no less famous among medically-inclined housewives.

Dr. Corvisart, of Paris, is asserted to have been the first to propose the use of the active principle of the stomach in feeble digestion; and of latter years the manufacture and consumption of pepsin have become very great. Various processes have been suggested for the preparation of the drug, but none of them yield a pure proximate principle, if indeed pepsin have really such nature and be not an albuminous body of varying constitution. By most of the methods of manufacture the pepsin is obtained in the form of a viscid fluid; and to change this into

a powder requires the addition of starch or sugar, so that the powdered pepsin, as sold, contains a considerable percentage of foreign material.

Whatever form of pepsin be used, if good effects are to be obtained from it it must be given with acid, unless indeed there be reason to believe that this constituent of the gastric juice is not wanting. Alcohol destroys the digesting power of pepsin, and therefore wines are inferior preparations of it. The reactions of pepsin with organic and inorganic matters are very complex, and not well understood: consequently I think the physician should eschew all elixirs or compound preparations of the drug, using only the powdered pepsin or a glycerole of pepsin, or a freshly-prepared digestive solution of water and muriatic acid, or glycerin, water, and muriatic acid. If other remedies are to be given, it is no great hardship to write a second prescription for them.

THERAPEUTICS.—It is a question of some importance to decide how far pepsin is valuable and reliable as a medicine. It is evident that any influence for good which it possesses is dependent upon its solvent power, and that this, therefore, is a measure of its value. According to the experiments of Dr. C. L. Dana, which seem to be very reliable, good pepsin ought to dissolve in the stomach twenty times its weight of albumen; and the U.S. Pharmacopœia requires that the pepsin, aided by hydrochloric acid, should dissolve fifty times its weight of coagulated egg albumen in five or six hours; but it is very doubtful whether twenty per cent. of commercial pepsin will do this. One of two conclusions seems to be inevitable: either the doses of pepsin habitually used are preposterously small, or else pepsin acts upon the stomach itself in some way as a stimulant. Clinically, pepsin has been used with asserted advantage in the *loss of digestive power* in adults, whether primary or occurring in the course of other affections. Probably four-fifths of the drug which has been given has been inert, either originally or from the method of its administration; and in the great majority of cases the good that has been achieved has been probably due, not to the pepsin, but to the regulation of the diet and habits of the patient and to the drugs which have been exhibited along with the animal ferment. Its value has been overestimated, and it has been given to adults in ridiculously small doses: at least half a drachm of the ordinary commercial article, or of the *Saccharated pepsin*, U.S., should be given at a dose. The testimony as to the usefulness of pepsin in diseases of young children is very strong. To such it is generally given in doses nearly as large as those usually exhibited in the cases of adults. If we represent the absolute digesting power of ten grains of pepsin as x , it is evident that x represents a proportionately much greater power in the *primæ viæ* of a child than in those of an adult. The use of small doses of pepsin in children is therefore much more rational than in adults; and my own experience is in close accord with what seem to me the dictates of common sense: in the *chronic indigestion* and consequent *diarrhœa* of young children it may be tried with great hope of

benefit. To a baby six months old five grains may be given in a little acidulated water at (U.S.) given in doses of ten to fifteen grains some digestive value.

PANCREATIN, U.S., has been extensively used as a digestant in lieu of pepsin. Its value is, however, doubtful, as for its action it requires the presence of an alkali, and without it would not only not act, but would itself be injured and destroyed as a ferment (*New York Medical Journal*). J. Milner Fothergill proposes to prevent this by administering ten to fifteen grains of sodium bicarbonate with each dose; but it is not probable that this amount will sufficiently alter the gastric juice to allow of the action of the pancreatin.

EXTRACTUM MALTÆ

Malt is the seeds of the ordinary barley at the earliest stage of germination by artificial means. It is prepared by soaking the grains in water, placing them at a temperature of moderate temperature, and by occasional turning given off during the process of germination, and finally killing the germ by heat. The color is brownish black, according to the degree of the heat. The extract formed during germination a peculiar ferment called diastase which is able to convert about two thousand grains of starch into dextrin and glucose. The *Extractum Maltæ* of the U.S. is made by rapidly evaporating an infusion of malt. It is a thick, honey-like liquid at a temperature of 100° F. The extract should contain practically all the diastase of the malt. The action of the extract of malt is slight and peculiar, it is slightly acid to paper distinctly acid. It dissolves in water, is precipitated by alcohol, tannic acid, mercuric chloride, and metallic salts. Commercial malt extracts vary much in strength and are practically preparations of glucose, other than strong or weak beers. True extract of malt is not used in all. Extract of malt has been largely used in cases of failing nutrition, and especially when the digestive system is feeble. When it contains largely starch it affords food-material to the system; but the question the therapist is, How far is it possible to rely on the digestion of starchy substances in the stomach without the use of diastase? R. H. Chittenden and G. H. Allen have made a series of investigations in order to determine the conditions necessary for the amylolytic action of diastase. They find that it acts better in a neutral than in an alkaline solution, and that it is more active when present in the alkaline solution than

ence of an alkaline carbonate; that neutral peptone exerts a direct stimulant effect on the amylolytic action, but that its greatest amylolytic action is observed in the presence of proteid matter partially saturated with acid, although a larger percentage of acid-proteids may cause complete destruction of the ferment. These results seem to prove that diastase, when taken into the stomach, must sooner or later be completely destroyed by the gastric juice, and that in order for it to have any distinct effect upon digestion it must be given at the beginning of the meal. In cancer of the stomach and other diseases in which the gastric juices lack acidity, the action of diastase upon starch must be more pronounced; but unfortunately the failure of the starch-digestion is usually associated with gastric hyperacidity.

PAPAIN.

The Carica Papaya is an herbaceous tree universally cultivated in tropical countries for its fruit, the papaw, the juice of which yields a peculiar ferment, to which the name of *Papain* was given by M. Wurtz, but which is now generally known by the name originated by Pekolt, *Papayotin*. This substance is a ferment, which has the power of dissolving fibrin, muscular fibres, tissues, etc. According to M. Wurtz, one part of *Papain* in alkaline solution at a temperature of 40° C. is capable of dissolving one hundred and seventy-five parts of moist fibrin, which it converts into a peptone. M. Wurtz affirms that it makes no difference whether the solvent solution be alkaline or acid, but Brunton, Wyatt, and Martin state that as little as one-half per cent. of hydrochloric acid arrests the digestion. Albrecht, however, reaffirms that hydrochloric acid hastens the action of papain, and states that the official preparation in use in the Paris hospitals is an acid one. Further, in an elaborate series of experiments, Dr. August Hirschler (*Ungar Archiv f. Medizin*, Bd. i., 1893) reaches the result that digestion goes on most rapidly in acid solution, that it is very feeble in alkaline solutions, and ceases entirely when the alkalinity becomes excessive. It is stated that in order to convert fibrin entirely into pure peptone, so that nitric acid will produce no precipitate, the proportion of the ferment must be at least three per cent., and the digestion must continue for forty-eight hours. Papain first coagulates milk, then precipitates it, and finally digests it into a thin fluid. Taken into the stomach, papain has no action upon the living tissues, but one grain of it injected directly into the blood is sufficient to cause death in a very short time in rabbits or in dogs. Its action on albuminoids is said to resemble that of trypsin rather than that of pepsin. (See Martin, *Brit. Med. Journ.*, July 25, 1885.) As it appears in commerce, papain is a grayish, very fine powder, which in its odor and taste strongly suggests pepsin.

THERAPEUTICS.—Papain has been used in medicine as a substitute for pepsin in the treatment of *dyspepsia* and *gastric catarrh*, in doses of five or ten grains. It has also been very highly recommended for the

purpose of destroying organic tissues of low type. Thus, in *diphtheria* the most remarkable results are claimed from its use, Dr. A. Jacobi (*Therap. Gaz.*, ii.) affirming, for instance, that in a few hours it entirely removes diphtheritic membranes if it be freely applied every hour, or more frequently, in the form of a mixture of one part of papain and two parts each of water and glycerin. It has also been employed for the destruction of the thickening of chronic *eczema*, of *warts*, of *pyogenic membranes* surrounding old sinuses or abscesses, and even of *epithelioma*. It is not caustic, but simply dissolves the diseased tissues, and is said to cause no pain. (See *Birmingham Med. Rev.*, May, 1886.) In experiments at the University of Pennsylvania commercial papain of the most esteemed brand failed to exert any solvent power over albuminous substances; and in the practical use of the remedy the practitioner should be careful to see that the material employed is active.

FAMILY IV.—ABSORBENTS.

THIS class contains remedies which are used for the purpose of absorbing acrid and deleterious materials, such as offensive discharges on the exterior of the body, and acrid secretions, or the irritant products of the partial decomposition of food, in the alimentary canal. For the first purpose very fine dry earth and plaster of Paris are used to some extent in practice; but, as their employment is purely in the province of the surgeon, I shall say no more about them here.

CHARCOAL.

Charcoal is official in the U.S. Pharmacopoeia in two forms:

CARBO LIGNI.—*Charcoal prepared from wood.*

CARBO ANIMALIS.—*Animal Charcoal, prepared from bone.*

Charcoal for medicinal purposes should be made out of a light, porous wood: that prepared from the young shoots of the willow or of the poplar is almost exclusively employed. It is a black, brittle substance, and should have more or less lustre. It has a very remarkable power of absorbing many times its own bulk of gases, and, when exposed to the air, increases rapidly in weight. It should therefore, when intended for medicinal purposes, be powdered as soon as it is burnt, and put in small, completely-filled, closely-sealed bottles.

Animal charcoal, or *bone-black*, formed as it is by the partial burning of bones, contains a large percentage of the phosphate and the carbonate of calcium. Although this does not interfere with its strictly medical employment, it does with many of its uses in pharmacy; and consequently the U.S. Pharmacopoeia directs that a *Purified Animal Charcoal* (*Carbo Animalis Purificatus*) be prepared by digesting ordinary animal charcoal in dilute muriatic acid, by which all the lime salts are dissolved out, washing thoroughly with water, and heating to redness.

Bone-black possesses absorbing powers far greater than those of ordinary or wood charcoal, and takes up coloring-matters, alkaloids, and other substances from solutions: it is therefore very extensively used in pharmacy, as well as in the refining of sugar, and in other processes of the arts.

THERAPEUTICS.—Charcoal is used externally as an absorbent and

disinfectant dressing to *foul wounds* and *ulcers* may be made by adding one to three drachms (or powdered charcoal to a flaxseed poultice; or, as directed, two ounces of bread may be well mixed with warm water, an ounce and a half of flaxseed added, and to the cataplasm thus formed two drachms of charcoal added, and one drachm sprinkled on the surface).

Internally, charcoal is employed as an antidote in *acute or chronic indigestion* in which there is accumulation of gases in the alimentary canal, giving rise to *flatulency*, *colic*, and similar disorders. It is at least given very freely should accumulate in the stomach, and mechanically cause serious trouble: for this reason it is generally combined with that of laxatives.

On account of its power of absorbing alkalies, charcoal has been recommended in poisoning by alkalis. Its action is, however, too slow for much good use. If given at all, it should be exhibited in large doses. Half an ounce of it is said to be required for the antidote of the poison.

ADMINISTRATION.—The ordinary dose of charcoal is from half an ounce to one ounce. Except in a mechanical obstruction, it is innocuous in any dose.

FAMILY V.—DISINFECTANTS.

DISINFECTANTS are substances employed for the prevention or destruction of noxious miasmata or effluvia. It is evident that the consideration of these materials belongs to the province of hygiene rather than to that of therapeutica, since their employment is hygienic rather than medicinal, preventive rather than curative. The importance of disinfection is, however, so great that I shall treat of it, although very briefly.

All disease-poisons may be divided into those which are generated or multiplied within the human body and those which arise solely without the body. To the former I shall apply the term "contagions," to the latter the term "miasma." Of the nature of miasma we have no definite knowledge, but it is probable that in many, if not all, cases they are organic entities. It is certainly established in regard to very many contagions that they are living forms, and for practical purposes all contagions must be considered to be of such nature. In the experimental study of the power of poisonous agents over the contagions, we are forced to take as the measure of the power of such agents the influence which they exert over the lower forms of life. We have no better criterion for judging of the effectiveness of disinfectant agents upon miasma. It must be remembered that these poisons are not necessarily connected with bad odors, but may in a most deadly form saturate the air in an apparently clean chamber, while the emanations from the most stinking cesspool may be free from them. It is probable, however, that foul gases are of themselves able to produce systemic depression, although not definite disease. It is, therefore, always important to prevent the giving off of foul gases from masses of decomposing matter.

An *antiseptic* is not always a *germicide*, though a *germicide* is always an antiseptic. The antiseptic is a substance which has the power of preventing putrefaction,—that is, the growth of the organisms which produce putrefaction; whereas the germicide is a substance which is capable of killing disease-germs and their spores, which entities are much more resistant than are the bacteria of putrefaction: thus, alcohol, common salt, borax, sulphate of iron, and many other agents commonly used as antiseptics do not even in concentrated solution destroy the spores of bacilli, and consequently are not germicides.

A question of very grave importance naturally arises here, as to the exact province of disinfection when applied to contagions; or, in other words, Is it possible to destroy them in the air? It is a law which holds everywhere, that the more imperfectly developed animal organisms are, the more tenacious are they of life; also experience has shown that all substances actively poisonous to contagions are still more poisonous to the germinal matter of human beings, and that it may be laid down as a general proposition that it is impossible to destroy the contagion-germs in the confined air of a room while men or women remain in the apartment. When it comes to the general atmosphere, to attempt to disinfect it, to essay the destruction of a wide-spread poison, such as, for example, exists in a smallpox epidemic, is simply so childish as to need no discussion to show its utter futility.* It is well known that contagions diluted beyond a certain point are powerless, and the admission of large quantities of *fresh or pure air*, or, in other words, *free ventilation*, is the only means at our command of disinfecting rooms in which there are human beings. In ventilating an apartment, it must always be remembered that it is not merely air, but pure air, that is required. To ventilate one room into another, as is sometimes done, is foolishness; to open a window with the wind blowing over a miasmatic swamp or an open sewer may be but to invite disease. The opportunity to destroy disease-germs is to be found not after they have been dispersed into the air, but while they are still in connection with the various solids and fluids passed from the body or brought in contact with it. In most, if not all, contagious diseases the poison-germs are eliminated in large quantities with the urinary and fecal discharges; it is of vital importance to act on the excretions as soon as they leave the body; and the disinfectant should be placed in the receptacle *before*, not *after*, it is used. To allow any excretion, sputum, or other infected discharge to exist for a moment undestroyed, or at least undeveloped, is most culpable neglect. Spit-cups, urinals, etc., should therefore have the disinfectant in them whilst waiting for use.

The nature of miasms is not known. Over many of them—malaria, for example—we have no control. Those which we are able to influence are almost all the results of animal or of vegetable decomposition, either alone or conjoined. After these poisons have been produced and diffused through the air, they are probably in great part beyond our reach. The only thing that can be done is to dilute them, precisely as in regard to contagions; and hence free ventilation is the only reliable disinfectant under these circumstances. The stinking gases are probably of use as indicators of the presence of more subtle poisons. The gases which arise from cesspools and similar depositories no doubt act as carriers of the peculiar poisons produced in these places, and it may be that destruction of the gas causes a deposition

* For failure of such an attempt, see *New Orleans Med. and Surg. Journ.*, Nov. 1871.

of the organic poison. This is, however, merely speculation: it is not proved. Moreover, the deposition of a poison in an apartment is no advantage. Even if it were possible to make an apartment appear to the smell pure by destruction of its stinking gases, no good would be accomplished by so doing. Wide-open windows, great draughts of fresh air, are the only proper disinfectants for a close room or a noisome hospital-ward. The attempt so often indulged in to purify such apartments by little saucers of chlorinated lime or of carbolic acid would be exceedingly ludicrous if it were not for the frightful results of the false sense of security engendered.

It is otherwise when the gases are destroyed at their places of emanation. Thus, if a sewer be belching forth deleterious gases and poison, chlorinated lime or other materials generating disinfecting gases at the mouth, or in the sewer, may really be of service by destroying the noxious vapors before they find their way out and carry with them into the air the poisonous effluvia.

Although miasms cannot be readily destroyed when once generated, yet in very many instances we have power to prevent their formation. In doing this the chief factor is *cleanliness*, and the best disinfectant is *water*. Water acts chiefly in two ways: first, by dilution; secondly, by destroying organic substances. In order for decomposition to produce serious poisoning, the mass of material must be considerable. If the matter be diffused through a large bulk of water, and this spread over a considerable surface, it is evident that the effect of dispersion is obtained. Further, when water containing organic matter is allowed to run away in its natural channels, oxidation and destruction of the impurities result. Without entering further into the subject, it is sufficiently evident that, so far as miasms, and also disease-germs in the air, are concerned, *air and water are the great disinfectants*, and that the most skilful use of chemical substances cannot take the place of ventilation and cleanliness. Moreover, antiseptics may do harm by delaying the destruction of filth by putrefaction, which latter process is simply nature's method of getting rid of filth. Destructive—that is, oxidizing—disinfectants, rather than antiseptics, should be used in cesspools. On the other hand, when the contents of a privy or other organic mass has been infected by disease-germs, it is essential to kill such germs by a germicidal agent.

The most complete and thorough, but the most destructive, of all disinfecting agents is *fire*. *Heat* of less intensity may be used either *moist* or *dry*. In the early part of the present century Dr. Henry, of Manchester, showed that the activity of vaccine lymph is destroyed by moisture at 140° F. in four hours. Drs. Carsten and Coert have also proved that calf lymph is at once sterilized by boiling water. Dr. George N. Sternberg found that boiling water will quickly destroy the vitality of all organisms known as disease-germs. This accords with the experiments made with hot air in the laboratory of Koch, in which it was

found that all bacteria are killed by an exposure of one hour and a half to the temperature of 212° F. with moisture. Similar results have also been arrived at by other experimenters, and I think it may be considered as established that all non-spore-bearing infectious bacteria are destroyed by water or steam at a temperature of 212° F. The spores of the bacilli have, however, much greater powers of resistance. Dr. Sternberg found that boiling for two hours does not kill the spores of *Bacillus subtilis*, although a more prolonged boiling is fatal, but the steam at a temperature of 110° C. (230° F.) for one or two minutes, or 105° C. (220° F.) maintained for ten minutes, will infallibly kill the spores. If dry instead of moist heat be employed, a much higher degree of temperature will be required. In the experiments of Koch and his assistants with dry hot air, the spores of mildew required for their destruction exposure for an hour and a half to a temperature of 230° F. the spores of bacilli an exposure of three hours to a temperature of 204° F. All observers find that the addition of steam to dry air increases greatly its destructive effect. Wolf (*Virchow's Archiv*, vol. ci p. 81) found that dry air at 140° C. was scarcely more destructive than watery vapor at 100°; Koch, that five minutes' exposure to steam was equal to an hour or an hour and a half with the dried air. The results reached by Koch and Wolffhügel (*Mitt. Kais. Gesundheitsamts*, Bd. i.) are in accord with our other evidence, and may be considered correct. They are as follows:

1. A temperature of 100° C. (212° F.), dry heat, maintained for an hour and a half, will destroy bacteria which do not contain spores.
2. Spores of mould-fungi require for their destruction in hot air temperature of from 110° to 115° C. (230°-239° F.) maintained for an hour and a half.
3. *Bacillus*-spores require for their destruction in hot air a temperature of 140° C. (284° F.) maintained for three hours.
4. In dry air the heat penetrates objects so slowly that small packages, such as pillows or small bundles of clothing, are not disinfected after an exposure of from three to four hours to a temperature of 140° C. (284° F.).
5. Exposure to a temperature of 140° C. (284° F.) in dry air for a period of three hours injures most objects requiring disinfection (clothing, bedding, etc.) to a greater or less degree.

Dr. George H. Rohé (*Med. News*, 1885, i. 283) found that rolls of blankets exposed in a chamber heated to 280° F. for three hours were very slightly affected in their interior. This is in strict accord with the teaching of Drs. Parsons and Klein, of the London Local Governing Board (*Report*, 1885), and of other observers. I think that the superiority of prolonged boiling over other methods of application of heat is established. In the sick-room, objects which can be boiled without injury should, immediately after their infection, be gathered into a close bundle, enclosed in a sheet, and as soon as possible thrown

into boiling water without opening. When pillows, bedding, or articles of furniture are seriously affected, they should be taken apart and exposed to heat and steam. For further details as to apparatus the reader is referred to the report of Parsons and Klein, already alluded to.

LEAD AND IRON.

There are various metallic salts which are believed to act as disinfectants by uniting with the sulphur of sulphuretted gases and precipitating as sulphurets. As examples of such may be mentioned sulphate of zinc and nitrate of lead. Under the name of *Ledoyen's Disinfectant Solution*, a solution of the latter salt has been and still is used to a considerable extent as a disinfectant. Although it certainly destroys sulphuretted hydrogen with great rapidity, it does not seem to me a good material for the purposes to which it is applied. The reasons for this are—first, it has no action besides that of a desulphurating body; second, it is a comparatively dear salt; third, it forms an intensely black precipitate, discoloring everything with which it comes in contact.

The power which the *oxides of iron* have of converting ordinary oxygen into ozone has already been spoken of (p. 520). This action is a slow, persistent one, and the oxidation which results is equally slow and persistent. As already stated, organic matter, if diffused through water and exposed to the air, is gradually destroyed by oxidation. It has been found that when water which is loaded with the products of decomposition is exposed to the action of iron plates, or even of iron pipes, this destruction of organic impurities is greatly hastened. According to Mr. G. Michaelis (*Phila. Med. Times*, vol. iii. p. 621), even the most filthy water, under the influence simply of iron plates and the air, will become perfectly pure in forty-eight hours. The action is evidently one of oxidation, but is in its details complicated. According to the researches of Dr. Mankiwich, iron possesses the property of converting ammonia into nitric acid, and also facilitates, or even provokes, such decomposition in the organic matter as shall cause ammonia to be formed. The nitric acid thus generated is one of the most powerful oxidizing substances known, and as fast as formed attacks the organic matter. It is evident that in this process the iron acts as an intermediate agent between the air and the decomposing matter; that, unlike the permanganate of potassium, it does not itself undergo a conversion equivalent in chemical relation to the oxidation, and consequently that its power is not so limited as that of those compounds. The iron, however, undoubtedly suffers to some extent, and is largely oxidized; but the oxide formed has certainly the power of generating more, and very probably to as great an extent as the original metal. How soon the power of oxidation is finally lost, and what eventually becomes of the iron, in the presence of an overwhelming mass of organic matter, has not, that I am aware of, been determined.

COPPERAS, or *impure sulphate of iron*, is an infectant, although, according to recent experiments, it has no oxidal power.* The changes wrought by such a mass of decomposing matter are very well known. In the first place, if sulphuretted hydrogen is present, a sulphuret of iron is at once precipitated; the salt is decomposed by the ammonia, and the volatile alkaloids which exist in the decomposition, by oxidation, in all probability, some of which are changed into the sesquioxide, by which the compound is doubtless exerted long after the decomposition of the salt. The sulphuric acid set free from the decomposition, in part to a feeble extent in the destructive process. From what has been already stated, it is evident that the use of the copperas is in altering the course of putrefaction and its products. If a rapid effect is desired, or if it is to be acted on, the copperas should be in solution; if action is wanted, or if the mass is liquid, the addition of stein, or using a parchment sack, may be resorted to; or it may be scattered over the surface of the mass.

LIME is probably the oldest of all the only as a destructive agent,—i.e., as causing the decay of organic matter. It is notorious that a compound of lime has been added rote—i.e., oxidizes—much more rapidly than none of the alkaline earth in it. This action is slow for ordinary purposes: moreover, there is no objection to the use of lime as a disinfectant.

The poisonous principles contained in a nature may be, are probably volatile, and lib sets free large quantities of ammonia in an composition. It may be that volatile pois with the ammonia; but, whether they are

* That this substance is of great practical value for disinfected by the experiments of Albert Eckstein, who published *Vermies*, Feb. 10, 1873) an account of his attempts daily by one hundred persons: 1. Two pounds of the used. After from two to three hours all bad smell had the influence of the disinfectant was lost. 2. The sulphation; result the same. 3. Two pounds of the sulphate their effects lasted two days. 4. The sulphate of copper solution rapidly lost its effect, and was exceedingly irrit. Two pounds of impure carbolic acid filled the house smell that it was impossible to tell whether the original of Two pounds of sulphate of iron in a parchment sack exert full days, and when the parchment sack was drawn up fluid. 5. Two pounds of the best chlorinated lime in the privy for at least nine days.

physical fact that a volatile substance in escaping carries off with it even non-volatile materials, and facilitates to a still greater degree the escape of principles only less volatile than itself.

Lime is, for the above reasons, not available for use as a disinfectant in cesspools and sewers unless it is added in large quantities day by day from the beginning, so as to keep the collection under its influence, and unless some absorbent is added with it to take up volatile principles. In the ordinary open privies of the country, a shovelful of a mixture of lime and plaster of Paris, or of lime and dry earth, thrown in day by day, will tend to prevent odor, and at the same time will prepare the contents for use as manure.

When spread upon walls in the form of whitewash, lime may act to some extent as an oxidizer; but probably its chief influence is as an absorbent, which takes up the deleterious emanations. A very striking illustration of this action of whitewash occurred some years since in the New York city hospital. A ward which stood isolated from the remainder of the institution had been used for the reception of cases of typhus fever from the shipping of the port. It was finally abandoned and allowed to stand unoccupied, with its windows wide open, for several months. At the end of this time, a gang of men were set to scraping the whitewash off the walls. Of these workmen a majority were seized with the ship-fever, and several died.

CORROSIVE SUBLIMATE.

In 1870, Dr. John Dougall announced that corrosive sublimate one part in sixty-five hundred would kill spermatozoa, and one part in six thousand infusoria; the later researches of Koch, Jalan de la Croix, and Sternberg have more than confirmed this result, and shown that corrosive sublimate is one of the most powerful of known germicides. Micrococci and bacilli in active growth without spores are killed by solutions of one in twenty thousand, while solutions of one in one thousand will rapidly destroy the spores of *B. anthracis* and *B. subtilis*. Results contrary to these have, it is true, been obtained by Klein of London, who asserts that a one-per-cent. solution of the mercuric chloride is no more a germicide than is vinegar; but the evidence to the contrary is so strong that it seems almost a certainty that there is some error in Klein's experiment. According to the detailed experiment of Koch, the spores of *B. anthracis* are absolutely incapable of germinating in a proteid solution if as little as one part of corrosive sublimate in three hundred thousand be present. Dr. Sternberg confirms the experiments of Koch, and it would theoretically appear that one part of corrosive sublimate in one hundred thousand is sufficient to destroy germs in a mass of filth, provided the filth is so situated that the corrosive sublimate will remain in contact with it for some time. It must be remembered, however, that corrosive sublimate is readily decomposed by the ammonia and other

chemical substances in a mass of filth, and it is very doubtful whether in practice it will be found that the mercuric chloride is available for disinfectant purposes on a large scale. Even, however, if its power be considerably less than they appear to be, it would still remain for many purposes the best of all germicides. A standard solution of one part in a thousand may be used for bedding, which can be soaked in it for washing the floors and walls of infected apartments, and for disinfecting the hands of surgeons and gynecologists; after the corrosive sublimate has done its work it should be removed by free washing with pure water. For the destruction of germs in fecal discharges, the solution should have at least the strength of one part in five hundred.

In regard to the use of corrosive sublimate in the treatment of wounds, etc., the reader is referred to treatises on surgery. It is, however, proper here to state that a number of cases of death from the local use of corrosive sublimate, especially in obstetrical and gynecological practice, have been reported. In most of these cases the solution has been at least one part in fifteen hundred; but I have known the use of a vaginal wash one in ten thousand to be followed by severe poisoning. It is probably very rarely proper to use continual irrigation of a mucous surface or of a wound with a solution stronger than one in ten thousand; and for a single washing the solution should not be more than one in two thousand.

CARBOLIC ACID.

Carbolic acid is an active and much-used germicide. For an account of its properties, see *ACIDUM CARBOLICUM*, p. 651; of its disinfectant value and use, p. 664.

CRESOLS—CRESYLIC ACID.

These compounds are the first homologues of phenol or carbolic acid. There are three isomeric cresols: *orthocresol*, *metacresol*, and *paracresol*, all obtainable by fractional distillation from that portion of coal-tar boiling between 200° and 210° C. Although Fraenkel long since established the germicidal activity of the cresols, their insolubility prevented their practical use. Recently, however, various preparations have been brought forward.

CREOLIN is said to be an emulsion of cresol, obtained by means of resin soap. There are in the market at least two sets of preparations: one German, the other English. Creolin forms a milky emulsion on mixture with water; with chloroform, ether, and absolute alcohol it mixes in all proportions.

According to Dr. Jessner, the first report upon creolin was that of Dr. F. von Esmarch (*Centralb. für Bacteriologie*, vol. ii., Nos. 10 and 11) who found creolin to be much more destructive than is carbolic acid to the bacteria of *Asiatic cholera*, of *putrefaction*, and of *typhoid fever*, but not so poisonous to the *anthrax* bacillus. It is claimed for creolin the

it is not poisonous. Dr. Jessner (*Lond. Med. Rec.*, Aug. 1889) gave eight ounces (250 Gm.) to a cow without any effect; and daily doses of 120 grains (7.77 Gm.) were given to a man without any noticeable effect except decrease of intestinal fermentation and gases. The urine also required longer than usual for ammoniacal fermentation. Nine hundred grains (60 Gm.) are said to have been taken without bad effects. Neudorfer, however (*Internat. Klinisch. Rundsch.*, April, 1888), has shown that injection of creolin into the venous circulation of dogs produces a marked effect, but this may be mechanical and due to the insolubility of the remedy; and fatal human poisoning has occurred. Dr. Bitter (*Brit. Med. Journ.*, 1890) has seen restlessness, anxiety, nausea, amblyopia, and a tendency to syncope, with a peculiar strong taste of tea or smoke, produced by the drug. The urine in some of these cases was dark and strongly albuminous, evidently acute nephritis having set in. Dr. Fliesburg (*Northwestern Lancet*, Dec. 1891) details a case of a three-weeks-old babe who was killed by 30 drops of undiluted creolin, the chief symptoms being those of violent irritation of the mouth and upper respiratory and digestive tracts. Death occurred chiefly through inflammation of the glottis.

Compared with other antiseptics, creolin seems to be almost innocuous. Externally, according to Neudörfer, the solution of 1 to 5 per thousand is non-poisonous and very antiseptic. He claims that it does not affect the hands or instruments of the surgeon, and is the best of the antiseptics for practical purposes. *Creolin gauze*, as usually sold, contains from five to ten per cent. of the creolin; Neudörfer believes that the one per cent. is sufficiently strong. He recommends, especially for local use, the creolin in a powder combined with asbestos, in the proportion of five to one hundred; and for the disinfection of catheters and other instruments, a thirty-three-per-cent. solution with olive oil. Internally, creolin is probably a very important remedy when it is desired to check fermentation in the alimentary canal. Locally applied, it has been largely used with great success in the treatment of *scabies*, in the form of a five-per-cent. ointment with vaseline. In *ammoniacal cystitis*, washing out the bladder with a half-per-cent. solution of creolin has yielded excellent results. It also seems to be a very effective local application in the treatment of *acute and chronic dysentery*, and also in the *cholera morbus of children*. In the case of adults, large enemata of a one-half-of-one-per-cent. solution may be used; in the case of infants the strength should be about one-half of this. As a local application in *gonorrhæa*, creolin has been used with alleged most excellent results, both in the form of bougies containing half a grain of creolin, and the injection of creolin dissolved in olive oil (1 in 3). For washing out the uterus after labor, the strength of the creolin solution should be one per cent.

LYSOL is a brown, oily-looking, clear liquid, with a feebly aromatic, creosote-like odor, which is said to contain fifty per cent. of cresols,

and to form with water a clear soapy liquid, and to be miscible also with alcohol and glycerin. According to Dr. V. Gerlach (*Zeit. für Hygiene*, June, 1891), it is more powerful as a germicide than is creolin and yields a one-per-cent. soapy solution which may be used for the purpose of surgical disinfection of the hands without the addition of soap. He claims that it is especially valuable for the disinfection of sputa, fecal, or other discharges, and that its one- to three-per-cent. solution is free from irritating properties and may be used for the disinfection of wounds, abscesses, etc. Its value as an antiseptic has been confirmed by Vulpinus, Michelsen, Lemke and Straube, etc.; but various surgeons have stated that it is more irritating than was at first alleged. Szuman (*Nowiny Lekarskie*, June, 1891) declares that even its parts in a thousand are irritating to the bladder. It does not injure the surgeon's hands or his metallic or rubber instruments; but cellulose articles are said to become friable and useless under its action. Toxicologically and physiologically, it probably is almost identical with creolin, and in sufficient dose may produce fall of temperature and general depression, with nephritis.

CRESOL IODIDE, or *Losophan*, is a fine yellowish powder, insoluble in water, but very soluble in oil, which has been especially used in surgery as a local antiseptic, astringent alterative.

CRESOL SALICYLATE, or *Cresalol*, is affirmed by Mr. Nencki (*Comp. Rend.*, Feb. 1889) to undergo decomposition in the intestines, yielding cresol and salicylic acid. It is said to act very much as does salol, but to be less poisonous on account of the great insolubility of cresol.

POTASSII PERMANGANAS—POTASSIUM PERMANGANATE. U.S.

This salt is prepared by heating together ten parts of binoxide of manganese and twelve parts of potassa. It occurs in slender, prismatic crystals of a dark-purple color, inodorous, of a sweetish, disagreeable taste, and very soluble in water, with which they form a solution varying from a purplish black to a beautiful reddish lilac, according to the strength. When kept dry and not exposed to the atmosphere, permanganate of potassium is a permanent salt, but whenever in solution it is brought into contact with an organic body it at once gives up its oxygen to the latter and is converted into potassa and black oxide of manganese.

The disinfectant power of this salt is beyond question; but at the same time this power is very limited, as the remedy yields up its own oxygen and becomes inert. According to the experiments of Dr. Georg M. Sternberg (*Med. News*, Jan. 10, 1885), as a germicide the permanganate is very potent, 0.12 per cent. (one part in eight hundred as

thirty-three parts) killing the micrococci of pus in two hours. For practical purposes, however, this agent is of very little value as a germicide, because it is at once decomposed by organic matters, and while in the laboratory disease-germs may exist almost isolated, in the sick-room they are mixed with a large excess of organic material. Nevertheless the permanganate affords a very elegant disinfectant and germicidal wash for wounds, ulcers, abscesses, etc., *fetid oræna*, *otorrhæa*, *leucorrhæa*, etc. In dilute solution its local influence is stimulant and beneficial. When employed in the form of powder it even affects living tissues, acting as a mild caustic, and, as such, may often be applied with advantage to *sloughing ulcers*. As a wash, the strength may vary according to circumstances, from one to twenty grains to the ounce. The injection of a strong solution of permanganate of potassium in the immediate neighborhood of venomous bites is said to be very effective. (For cases, see *Texas Courier-Record*, vi., 1888-89.) The action of the permanganate in these cases is that of a destructive oxidizant. Dr. William Moor (*New York Med. Rec.*, Feb. 17, 1894) announced the fact that potassium permanganate is an antidote for morphine, one grain of it being sufficient to almost immediately destroy one grain of the alkaloid. It has also been claimed that the permanganate is capable of acting upon morphine in the blood, so that the intravenous or even hypodermic injection of it, hours after the ingestion of the alkaloid, will bring immediate relief.

In an unpublished and, indeed, at present unfinished research I have found that the permanganate will, when given sufficient time, destroy most, if not all, alkaloids. With cocaine it forms an immediate copious precipitate. Upon strychnine it acts more slowly. My experience indicates that it has practical value in morphine- and probably also in cocaine-poisoning, if it can be administered not too long after the ingestion of the alkaloid. The claim that it is capable of neutralizing the poison in the blood is on the face of it extremely improbable, as it does not seem possible that the permanganate can be absorbed as a permanganate. Moreover, in a number of experiments made upon the lower animals with morphine, I have found that the hypodermic injection of the permanganate does no good whatever in morphine-poisoning; indeed, the local effect of the permanganate, when used freely, has invariably hastened the death of the animal.

CHLORUM—CHLORINE.

Chlorine gas is officinal only in the form of the *Aqua Chlorig*, which is prepared by heating together black oxide of manganese and hydrochloric acid, and allowing the chlorine which is generated to pass through water until the latter is saturated. *Chlorine Water* is a greenish-yellow liquid, of a very sharp taste, and having a strong odor of chlorine. When it is desired to liberate chlorine in the air of a room, eighteen parts of finely-ground common salt with fifteen parts of finely-

powdered black oxide of manganese should be introduced into a flask; then there should be added forty-five parts of concentrated sulphuric acid and twenty-one of water, previously mixed and *completely cooled*; and, lastly, the flask is to be well shaken. When the evolution of gas ceases, it may be renewed by placing the flask in warm water.* When chlorine is brought into contact with organic substances and moisture, it unites with the hydrogen of the water and liberates nascent oxygen, which rapidly oxidizes and destroys the organic compound. When chlorine comes in contact with sulphuretted hydrogen, it removes its hydrogen and thereby destroys it.

The germicidal influence of chlorine is very great. Fischer and Proskauer found that dried anthrax spores maintained their integrity for one hour when exposed to the action of a dry chlorine atmosphere containing 44.7 parts of chlorine in 100. When the air and the spores were moist, one hour's exposure to an atmosphere containing four per cent. of chlorine produced complete disinfection. If the exposure was continued for three hours, one per cent. of chlorine was an efficient germicide; and if the spores were exposed for twenty-four hours, the effective proportion of chlorine could be still further reduced. In Dr. Sternberg's experiments (*Rep. Nat. Bd. of Health*, 1880), six hours' exposure of vaccine lymph dried upon ivory points to an atmosphere containing one part of chlorine in two hundred was sufficient to destroy the infective property of the lymph, while the bacteria of putrid urine were destroyed after six hours' exposure to an atmosphere containing one part of chlorine in four hundred. Dr. Klein also found (*Report of the Local Governing Board*, vol. xiii., 1883 and 1884, Supplement) that after the compartment of a stable in which pigs had died of swine-plague had been thoroughly fumigated for six hours with chlorine, healthy animals could be placed therein with safety.

The result of all our knowledge upon the subject of the disinfectant properties of *chlorine*, *iodine*, and *bromine* is summed up by Dr. Geo. B. Rohé (*Med. News*, xlii. 89) as follows:

1. Chlorine is an efficient disinfectant when present in the proportion of one part in one hundred, provided the air and the objects to be disinfected are in a moist state and the exposure continues for upwards of an hour.
2. Chlorine, when used in sufficient concentration to act as a trustworthy disinfectant, injures colored fabrics and wearing-apparel.
3. Bromine is an efficient disinfectant in the proportion of one part in five hundred, provided the air be in a moist state and the exposure continues for upwards of three hours.
4. Iodine, in solution, is an efficient disinfectant in the proportion of one part in five hundred, the exposure continuing for two hours.

* Inspired in sufficient amount, chlorine gas produces, both in man and in the lower animals, narcotism, and finally death from paralysis of the respiratory centres (consult *Arch. f. Exper. Path. u. Pharm.*, xiii.).

5. The use of chlorine, and in a greater degree of bromine, requires considerable experience in management: when carelessly handled they may cause inconvenient or even dangerous symptoms in persons using them; hence they are not suitable as disinfectants for popular use.

Internally, chlorine water has been used in various diseases, especially in malignant typhus, but at present is rarely if ever so employed. It is stated to be stimulant and tonic to the stomach, and is thought by some to have an especial influence upon the liver. It has been employed in chronic hepatic affections; the dose is half a fluidrachm to two fluidrachms in three or four fluidounces of water. Chlorine water is a powerful irritant, capable of producing severe inflammation of the skin or toxic gastro-enteritis. Properly diluted, it forms an excellent stimulant, disinfectant, detergent wash for foul ulcers, and may also be used as a gargle in malignant sore throat.

CALX CHLORATA—Chlorinated Lime. U.S.—In ordinary life chlorine is chiefly used as a disinfectant in the form of a grayish-white substance occurring in powder or friable lumps, having a hot, acrid, astringent taste, and an odor resembling that of chlorine. It is made by the action of chlorine upon hydrate of calcium, or slaked lime, and should contain at least twenty-five per cent. of chlorine. It probably varies in its chemical constitution, but, according to the most recent views, is chiefly composed of the hypochlorite and the chloride of calcium. When exposed to the air it slowly evolves hypochlorous acid, which, being an unstable compound, undergoes spontaneous decomposition, and finally sets free fourteen-fifteenths of its chlorine. When an acid is added to chlorinated lime, the chlorine gas is rapidly evolved. If a specimen of bleaching-powder be very moist, it generally contains an over-proportion of the deliquescent chloride of calcium, and is correspondingly unable to liberate chlorine.

The experiments of Dr. J. R. Duggan (*Med. News*, xli. 147) indicate that the hypochlorites are among the very best of our practical disinfectants. He found that 0.25 of one per cent. (one part to four hundred) of chlorine as hypochlorite is an effective germicide even when allowed to act for only two minutes; while 0.06 of one per cent. (six parts to ten thousand) will kill the spores of *B. anthracis* and *B. subtilis* in two hours.

Bleaching-powder usually contains from twenty-five to forty per cent. of available chlorine. For most purposes, a solution containing one part of this preparation to one hundred parts of water is strong enough, for this will contain from 0.25 to 0.40 of one per cent. of chlorine as hypochlorite. As is stated above, the smaller of these quantities is sufficient to destroy spores almost instantly. There are very few purposes to which disinfectants are applied that are not fulfilled by this solution of one to one hundred of bleaching-powder. It is not danger-

ously poisonous, is said not to injure clothing, bedding,* etc., and is very cheap, since bleaching-powder is worth only about five cents per pound.† For the destruction of disease-germs in urine, fecal discharges, sputum, etc., a saturated solution of bleaching-powder appears to be in all respects the best disinfectant known: for the purification of cesspools, sewers or similar receptacles, or of masses of infected filth, the chlorinated lime stands at the head of known germicides.‡

* This statement seems to me doubtful.

† To fix the value of solutions of the hypochlorites, the following method is, according to Duggan, sufficiently accurate for ordinary purposes. A standard solution of potassium arsenite may be made by diluting seven parts of Fowler's solution with one and a half parts of water. This corresponds to a one-half-per-cent. solution of available chlorine. To apply the method a given volume of the hypochlorite solution is measured out, and the arsenite solution added in small quantities. Between each addition the mixture is well stirred, and a drop taken up on a glass rod and tested on a strip of paper saturated with iodide of potassium and starch paste and dried. As long as any hypochlorite is present, the blue iodide of starch is formed, but when it has all been used up in converting the arsenite into an arseniate, the paper will remain colorless. As each volume of the potassium arsenite solution required for this corresponds to one-half per cent. of available chlorine, the calculation is very simple: e.g., if a volume of the hypochlorite solution = 4.6 volumes of the arsenite solution, the amount of available chlorine present would correspond to 2.3 per cent. Since the preparations now in the market vary so much in the amount of chlorine they contain, this test should always be used to determine their value and the amount of dilution required.

‡ There are not many affairs in life in which the public have been so superabundantly fleeced as in the matter of disinfection. A most extraordinary part of this swindling is the ease with which distinguished members of the medical profession have given certificates of efficiency and value to comparatively inert and extraordinarily expensive proprietary compounds. Oddly enough, the cat that has drawn the chestnuts out of the fire for avaricious manufacturers has not even had the sense to smell the odor of its own paws when burnt. There is no proprietary disinfectant whose value corresponds with its selling price. The following tables, taken from an article by Dr. A. W. Harlan, of Chicago, were compiled ten years since, but are probably still correct: of course, in them one unit is used throughout. The cost represents the same germicidal power throughout.

Name.	Full Cost.	Name.	Full Cost.
Corrosive sublimate	\$0.00 $\frac{1}{10}$	Corrosive sublimate	\$0.00
Chlorine01 $\frac{1}{10}$	Little's sol. phenyl	12.00

LIQUOR SODÆ CHLORATÆ, U.S.—*Solution of Chlorinated Soda*, or *Labarraque's Solution*, is an official preparation made by triturating chlorinated lime with a solution of the carbonate of sodium. It is a greenish-yellow liquid, having a slight odor of chlorine and a sharp saline taste. It contains, among other substances, hypochlorite of sodium, and possesses the therapeutic and disinfectant properties of the chlorinated compound. Owing to its liquid form, its comparative freedom from odor, and its depositing chloride of sodium on evaporation, it is the most elegant of all the chlorine preparations for use in the sick-room. Properly diluted, Labarraque's solution may be employed for all the therapeutic purposes that chlorine water is used for. The dose is half a fluidrachm to two fluidrachms, in half a tumblerful to a tumblerful of water.

ACIDUM BORICUM—BORIC ACID. U.S.

SODII BORAS, U.S.—*Borax*.—Boric (or *Boracic*) acid crystallizes in white translucent scales, soluble in about thirty parts of cold water, much more soluble in boiling water, which on cooling precipitates all but about twenty-three grains to the fluidounce. Hot glycerin dissolves and holds upon cooling as much as three drachms to the fluidounce. *Borax* occurs in white, flattened, prismatic crystals, soluble in twelve times their weight of cold water.

The action of boracic acid and its salts upon the animal system is a very feeble one. In experiments made by Dr. E. T. Stewart and myself, enormous doses were required to affect the frog; they depressed the spinal centres and produced progressive loss of voluntary and reflex activity without affecting nerve or muscle.* A saturated solution of the quadroborate of sodium brought in direct contact with the heart exercised a very feeble depressant influence, and when injected in sufficient amount into the jugular vein of the mammal lowered the arterial pressure. Cyon (*Hoffmann und Schwalbe's Jahresb.*, 1879, 301) found that daily doses of three drachms of borax increase the appetite and digestion in dogs without causing other effect, unless it be gain in weight. Although large amounts of boracic acid may be taken with impunity, yet a number of cases of poisoning are on record. The symptoms have varied somewhat, but in most if not all the cases there have been great depression of spirits, fall of bodily temperature, a very feeble pulse,—rapid or slow,—and an erythematous eruption accompanied with much swelling of the parts, and especially affecting the lower extremities and followed by exfoliation; nausea, violent vomiting, and

* A very curious effect is said (by Professor Schiff, *Rev. Méd. de Suisse Rom.*, 1851, 244) to be produced by the local application of boracic acid to nerves: the part affected is affirmed to lose its power of originating but not of transmitting impulses, so that if the galvanic current be applied to the part of the nerve which has been exposed to the drug no muscular contractions result, but if the poles be placed above this part the distal muscles respond at once.

hiccough have been present in some cases; ecchymoses have been noted; the mind usually remains clear until late in the poisoning, but death has been preceded by coma, with disturbances of the respiration and involuntary discharges. Cases: Dr. George T. Welch (*New York Med. Rec.*, xxxiv., 1888), two ounces of boracic acid in the vagina,—recovery; Mododewkow (*St. Louis Clin. Rec.*, 1881), death from washing out internal cavities with five-per-cent. solution; Hogner (*Schmidt's Jahrb.*, ccii., 238), death from washing the stomach with two-and-a-half per-cent. solution (see also *Med. News*, xl., 704).* Dr. G. Lemoine reports (*Bull. Gén. Thérap.*, May, 1892) a bluish-gray line, like that of lead-poisoning, as present upon the gums in cases of epilepsy in which borax had been given very freely and continuously.

Boric acid is rapidly eliminated with the urine, and also escapes in the perspiration, saliva, and feces (Dr. Johnson, *Therap. Gaz.*, iii., 114). According to Max Grüber (*Hoffmann u. Schwalbe*, 1879), it increases the elimination of urea as well as the flow in the urine. Johnson also states that it is diuretic, and Jacob Plaut (*Würzburg Thesis*, 1889) has shown that it may produce acute parenchymatous nephritis.

In 1874, Dumas and Schnatzles announced that borax is poisonous to the lower forms of life (*Pharm. Journ.*, April, 1874); in Bucholz's experiments, 0.75 per cent. of boracic acid was found sufficient to prevent the development of bacteria (*Arch. f. Exper. Path. u. Pharm.*, B. iv.). In the experiments of Dr. Walb (*Centralbl. f. Klin. Med.*, 188, iii. 529), a two-per-cent. solution of borax distinctly checked the putrefaction of solution of fibrin; a five-per-cent. solution kept the solution fresh for nineteen days. Fresh muscle-fibres from oxen were kept fresh many days by a one-per-cent. solution. In the elaborate experiments of Dr. Sternberg it was found that boracic acid and the bicarbonate of sodium are inefficient as germ-destroyers, but have considerable antiseptic power (*Amer. Journ. Med. Sci.*, lxxxiv., 321). These experiments of Sternberg receive corroboration by Dr. E. Andrew (*Chicago Med. Exam.*, lviii., 1889), and it would appear, therefore, that boracic acid is a feeble antiseptic. The acid has been used to a considerable extent in antiseptic surgery, and it is affirmed to be free from irritating properties, and of great practical value in the treatment of fresh wounds, foul ulcers, abscesses, old burns, etc. (see especially Dr. M. Greene, *Boston Med. and Surg. Journ.*, ciii. 209). A liniment may be made by saturating ordinary patent lint with a saturated boiling solution of boracic acid; wounds dressed in a dry manner with this are stated to heal as rapidly as when a complicated antiseptic is employed. Dr. Greene prepares an ointment by melting one part each of spermaceti and white wax with six parts of vaseline, and adding, while hot, two to four parts of a saturated glycerite of boracic acid. In the

* There is no reason for believing that boric acid had anything to do with the symptoms in the case of alleged poisoning reported in *Med. News*, xliii. p. 199.

form of lotion, the remedy has been used with great advantage in *phlegmonous erysipelas* (see *Lancet*, May, 1873; May, 1876; also Professor F. L. Lebovitz, *Gaz. Hebdom. de Med.*, 1884, xxi. 624). There can be no doubt of the value of boracic acid and borax as a local application in *aphthous ulceration*, *diphtheria*, and other inflammations of the mouth, in which crystals of the sodium salt may be allowed slowly to dissolve in the mouth; whether, as affirmed by Dr. William Greene and by Dr. F. P. Atkinson (*Lond. Practitioner*, xxiv. 254), boracic acid is useful in *septicæmia*, *puerperal fever*, *erysipelas*, etc., is more problematical.* Borax has been used in *epilepsy* with asserted good results, especially by Dr. C. F. Folsom (*Boston Med. and Surg. Journ.*, Feb. 18, 1886). He gives ten to fifteen grains three times a day. I have tried it in a number of cases, the only result being marked gastro-intestinal irritation. The statement of Professor Rosenthal (*Allgem. Wien. Med. Wochens.*, Jan. 1884) that boracic acid is efficient in *ammoniacal urine* and *cystitis*, acidifying the urine and checking the fermentation, has been confirmed (see *Lancet*, 1884, ii. 133). In the *cystitis of spinal diseases* I have secured great relief by washing out the bladder with a few ounces of a saturated solution of boracic acid after the use of the catheter. The acid may be given in doses of ten grains three to six times a day; the salt, twenty grains to a drachm: in each case administered in diluted watery solution. As a disinfectant and soothing eye-wash its solution is much used by oculists in conjunctivitis. The strength may vary from five grains to the ounce up to saturation. M. A. Dujardin (*Union Med. du Nord-Est*, Nov. 1891) states that borax is incompatible with the alkaloid.

ACIDUM SULPHUROSUM—SULPHUROUS ACID. U.S.

A somewhat elaborate study of the action of the sulphites upon vertebrata has been made by Dr. Pfeiffer (*Sajous Annual*, v., 1891), who finds that they are poisonous when in very large doses, but that the rapidity with which they are oxidized into the sulphate frequently brings about sudden recovery in the deepest condition of poisoning. In sufficient amount they are said to paralyze the blood-vessels, the heart, and the respiratory apparatus.

Sulphurous acid and its salts are most efficient in destroying the low forms of life which are connected with putrefaction and fermentation, and for this reason are excellent preservatives of organic matters; they are also among the oldest of disinfectants, having been used as long ago as 1771; but recent experimental evidence seems to indicate that they have not the great superiority which has been attributed to them.

* M. Cyon commends very highly the use of borax in daily doses of eighty to ninety grains as a prophylactic against *cholera*, and affirms that during the epidemic in Italy during 1864-65 none of the villagers employed in the borax-works were affected, while in a village in close proximity one-third of the inhabitants died. He believes that the drug kills the germs in the alimentary canal (*Compt.-Rend. Acad. Sci.*, 1892, 149).

According to the experiments of Sternberg, one volume of sulphurous acid gas in one hundred volumes of air is sufficient to disinfect dry vaccine matter. As these experiments are in accord with older observations, they may be considered as correct.

According to Wernitz, the action of pepsine, of ptyaline, of invertine, and of diastase is prevented by the presence of an aqueous solution of SO_2 of 1: 1317 to 1: 8600 (by weight); while the action of myrosine and of emulsine is neutralized by 1: 21,000. Wernitz further says that strips of woollen or cotton goods saturated with putrefactive matter are disinfected by exposure of from four to six hours to an atmosphere containing four per cent. of sulphurous acid gas. The very elaborate experiments of Koch, of Wolffhügel, and of Sternberg have shown, however, that when the infectious material contains spores sulphur dioxide is of very little value. Wolffhügel concludes that it should be abandoned as a disinfectant: nevertheless, as probably but few of the contagions are in the condition of spores, it is likely that sulphurous acid, when sufficiently concentrated, is an effective disinfectant, if applied for a sufficient length of time. It has been proved by the experiments of Sternberg that the gas acts much more freely and powerfully when the air is loaded with moisture. Fumigation of an apartment with sulphurous acid gas should never be allowed to take the place of cleanliness and thorough disinfection of the walls and of all articles of furniture. Whether after all this is done the fumigation does any good—whether in practice it is of any real value—remains doubtful. It is perfectly sure that it is of no service unless the air of the room be made to contain at least five volumes per thousand of the gas, and this for a period of from four to six hours. The following method is the one generally employed.

Take a large iron pot or caldron, put in it a little stand, such as the cheap tripod used by chemists, place on this an iron plate containing flowers of sulphur thoroughly wet with alcohol or (probably better still) with turpentine; underneath the plate set a tin alcohol lamp; then put the whole on bricks in the middle of the room. Light the lamp underneath the dish, and if the sulphur does not take fire previously, when it begins actively to melt, ignite it. Leave the room at once, closing the door. The room must be as tight as possible, the chimney-places, ventilators, windows, and doors of exit being closed, while all the drawers of furniture and the doors of closets should be widely opened.

Sulphurous acid may be used in a saturated solution for the purpose of destroying disease-germs in the excretions of the sick: * its action

* For a very interesting account, by Dr. J. Hjaltein, of the strangling of a smallpox epidemic in Iceland, see *British Medical Journal*, 1871, vol. II. p. 519. I cannot help believing that the strict isolation and quarantining of the sick had far more to do with arresting the spread of the disease than had the sulphurous acid employed.

upon vegetable colors of course completely unfits it for many uses. The sulphites and the bisulphites are largely employed to arrest or control fermentation in various processes in the arts.

NAPHTALINUM—NAPHTALIN. U.S.

Naphtalin is a hydrocarbon obtained by the fractional distillation of coal-tar, or sometimes by the dry distillation of organic bodies. It is a white, shining, crystalline substance, fusible at 176° F., insoluble in water, but soluble in alcohol, chloroform, and ether. It is poisonous to the lower forms of life, and under the name of *tar camphor* it has largely supplanted true camphor as a means of preventing the deposition by moths of eggs in woollen clothing, and the destruction by insects in natural history museums, etc. In internal medicine it was some years ago brought forward by Dupasquier as an expectorant especially valuable in *chronic bronchitis* accompanied with a large amount of secretion. It has also been used with asserted excellent results as a *tanicide*, and as a vermifuge in cases of *seat-worms*, when it should be given by injection, from fifteen grains to half a drachm in two to three ounces of olive oil. First employed by Professor Rossbach, of Jena, in *intestinal catarrh*, it has been largely given in all forms of *intestinal inflammation* and in *typhoid fever*. It has also been used externally as an antiseptic dressing, and as a local application in various skin-diseases. It has certainly proved effective in many cases, but has been supplanted by naphtol, which is similar to it in action and probably more effective. The ordinary dose is from two to eight grains, but as much as eighty grains per day are said to have been given with good results. It is best administered as a powder in capsules.

NAPHTOL—NAPHTOL. U.S. (BETA-NAPHTOL.)

Naphtol is a phenol which is present in small quantities in coal-tar, but is usually prepared artificially by heating naphtalin with sulphuric acid and fusing the resulting naphtalin-sulphonic acids with alkaline hydrates. There are two naphtols, alpha and beta, of which beta-naphtol is official. It occurs as colorless or pale-buff crystalline laminae, or as a white or yellowish-white crystalline powder, of a pungent but not persistent taste, and a faint odor suggesting carbolic acid. It is permanent in the air, very slightly soluble in water, very freely soluble in alcohol.

THERAPEUTICS.—The antiseptic and physiological properties of beta-naphtol were first studied by Bouchard and Maximovitch, who found that the strength of one to three thousand was sufficient to arrest completely the development of some pathogenetic germs in the agar tube, and greatly to retard the growth of the bacillus of typhoid fever and of tuberculosis; and that the dose of about three grains per quart (0.20 Gm. per litre) was enough to entirely stop the process of putrefaction when in full development. In a careful series of experi-

ments it was found that mercuric iodide is six times more antiseptic than beta-naphtol, but that carbolic acid is five times less antiseptic, and creosote four times less antiseptic. The toxic dose of beta-naphtol was found to be 3.8 per kilo of the animal, making it two hundred and fifty-three times less poisonous than mercuric iodide. At this rate the poisonous dose for an ordinary man would be between three and four thousand grains. In the animals killed by it, death took place through an arrest of respiration, the heart retaining its activity. As a practical remedy, beta-naphtol was first used in 1881 by Professor Kaposi, of Vienna, who found that in the dose of one gramme per litre it disinfects and deodorizes urine and fecal discharges, and that applied to the mucous membranes it causes at first a burning sensation and a local irritation, which disappears very rapidly. In solution either in oil or in alcohol it was much more irritating to the skin, one part to one hundred distinctly affecting *eczematous eruptions*, and one to one and a half parts per hundred being sufficient to provoke urticaria on a healthy skin. In the form of soap, containing two parts per hundred, Kaposi found it useful in *prurigo*, *ichthyosis*, *herpes*, and *favus*, obtaining in many cases the best results by alternating this soap with a sulphur soap, and avoiding in this way a cumulation in the system which he believed was possible by the absorption of the drug. The practice of Kaposi was followed by numerous dermatologists with success, and led to the use of the remedy locally in inflammation of the mucous membranes, such as *conjunctivitis*, *chronic laryngitis*, *otitis*, etc.

Professor Bouchard appears to have been the first to use the drug internally, first, to disinfect pathological cavities; secondly, for intestinal antiseptics, especially in *typhoid fever*. In order to determine whether digestion would be seriously interfered with by this agent. Mr. Clarke made a series of experiments of its effect upon artificial digestion. He found that it has a very distinct retarding influence on the digestion of egg albumen by peptic fluids, a very slight effect on the digestion of milk by the same, and no effect at all on pancreatic digestion of milk or albumen, nor on the conversion of starch into sugar. The paper of Professor Bouchard led to the use of beta-naphtol in typhoid fever by a large number of clinicians, and the reports are very strongly in its favor. It is borne well both by adults and by children, rapidly lessening the diarrhoea and other local abdominal symptoms, an amelioration which is said almost invariably to be followed by marked subsidence of the constitutional disturbances. Naphtol has also been used with asserted good results in almost all forms of *diarrhoea* and of *dysentery*. It has also been employed in *dilatation of the stomach*, and in *dyspepsias* of various character, in which, however, the reports of its action are distinctly less favorable. It has even been injected into the trachea by M. Pignol, in *pneumonia*, with asserted good results, two to three hundred cubic centimetres of a solution of one part per thousand being thrown, drop by drop, during

a half-hour, into the trachea by a syringe. Teissier is said to have given it intravenously. It has also been employed, with asserted excellent results, in epidemic *influenza*, and in low fevers with albuminous urine, causing the albumin to disappear. As an intestinal disinfectant it appears to be one of the best, if not the best, of known drugs. The dose of naphthol is usually set down at from three to four grains (0.20 to 0.25 Gm.), given in capsules every two hours, but it is probable that much larger doses may be used with safety. The following formula may be used in the making of the solution: 1. *Weak solution*, for parts in which mucous membranes are exposed: naphthol, 5 grammes; alcohol at 60° F., 1 litre. 2. *Ordinary solution*: naphthol, 15 grammes; alcohol at 60° F., 1 litre. 3. *Strong solution*, for touching diseased portions of the skin, or septic excoriations: naphthol, 15 to 500 grammes per litre. 4. *Solution for interstitial injections, or closed septic cavities*: naphthol, 5 grammes; alcohol at 90°, 33 grammes; hot distilled water, to make 100 cubic centimetres; filter, and use warm. A few drops may be injected into indurated glands or abscesses.

AQUA HYDROGENII DIOXIDI, U.S.—Solution of Hydrogen Dioxide (Solution of Hydrogen Peroxide).—This is a colorless, odorless, slightly acid, aqueous solution of Hydrogen Dioxide [$H_2O_2 = 33.92$], containing, when freshly prepared, about three per cent., by weight, of the pure dioxide, corresponding to about ten volumes of available oxygen. It was discovered by Thénard in 1818, but in 1890 first earned recognition in the U.S. Pharmacopœia. It consists of solution of water in which, by the presenting to it of oxygen in a nascent state, an additional atom of this element has combined with the hydrogen, forming the dioxide, $(HO)_2$, or H_2O_2 ; a small amount of free acid is always left in it as a preservative. At best it is apt to undergo decomposition, and it should be kept in a cool place, and not too tightly stoppered, particularly in hot weather, lest there should be such a brisk evolution of oxygen in a confined space as to cause an explosion.

THERAPEUTICS.—Hydrogen dioxide was originally suggested by Dr. B. W. Richardson, of London, as a powerful oxidizant of organic matter, and as a substance having remarkable physiological properties. In attempting to investigate its physiological action, I found that its solution injected into the blood-vessel so immediately coagulates blood that it does not seem possible for it to find entrance into the circulation. Moreover, it is extremely improbable that any of the dioxide can find its way into the system when the solution is given by the mouth, as it would destroy itself by acting upon the organic contents and secretions of the gastro-intestinal tract. Such reasoning as this indicates the incorrectness of the value attached to the drug, as long ago as 1868, by Dr. John Day and other clinicians, in *low fevers*, *diabetes*, and other diseases: and, on the whole, clinical experience has strongly corroborated the *a priori* reasoning; so that as an internal remedy aqua

hydrogenii dioxidi has not acquired favor, although its power as remedy is everywhere recognized. It is a powerful coagulant *in situ*, and when brought in contact with mucous membranes or ulcers surfaces rapidly evolves gas, at the same time forming a dense coating. When brought in contact with pus it effervesces very rapidly and rapidly destroys the pus-corpuscles, which immediately become granular, lose their shape, and break up into detritus. It is a powerful deodorant, rapidly oxidizing hydrogen sulphide and other gases. Further, it is a very powerful germicide.

It has been experimentally shown by Dr. Pane (*London M. J.* Jan. 1891) that (1) Hydrogen peroxide in a solution of 1 to 1000 has energetic disinfectant power. (2) The solution 1 to 1000 is antiseptic, and inferior to the corresponding solution of corrosive sublimate. The solution of H_2O_2 in nutritive substances, 1 to 352, impedes the development, but after some days kills the spore-bacillus of charbon. (3) The solution of H_2O_2 in nutritive substances from 1 to 352 to 5052, impedes the development of the spore-bacilli of charbon, but does not deprive them of their germinative power when they are transferred to another nutritive substance. Thus, oxygenated water in nutritive substances has a more powerful action on the spores of the bacillus of charbon than has corrosive sublimate, since the spores can develop freely in a solution of 1 to 1000 of the mercurial; a conclusion which has been confirmed by Miguet and others.

As a means of purifying water it has the great advantage of not injuring the taste or harmlessness of the water. According to Hoefer (*Central. f. Bact. u. Paras.*, viii., 1890), cholera, typhoid, and other pathogenic microbes are killed in sewage by one part in ten thousand in twenty-four hours. Gifford found that the fifteen-volume solution was capable of killing even fully-developed anthrax spores in three-quarters of a minute (*Med. and Surg. Rep.*, lxiv., 1891).

Its liquid form makes it especially adapted for putrid cavities, abscesses, which it will thoroughly cleanse. It cannot, however, take the place of such antiseptics as mercuric chloride, because its action is so immediate and fugacious. As a preventive antiseptic it has little value. For disinfecting the hands and instruments of the surgeon it has the great advantage of immediate and powerful action and of not staining the hands or clothing. By some surgeons it is said not to affect the instruments.

As a local application in specific inflammations of mucous membranes hydrogen peroxide is of greatest value. In scarlet fever and diphtheria the official solution may be applied by mop to the pharynx, with extraordinarily good results. Diluted one-half, it may be injected into the nasal cavities when they are affected. Injection of a solution from twenty per cent. to full strength has received commendation in the treatment of gonorrhœa and chancre. The official solution

been used with alleged great success as a local styptic. It is probably for practical purposes free from poisonous properties, the fatal results which Dr. Pane produced by injecting the strong solution directly into the peritoneal cavity of the rabbit being, in all probability, due to the shock produced by the intense local irritation of the peritoneum. Death from shock also affords the most plausible explanation of the case reported by Dr. Laach (*Lancet*, Oct. 1886), in which six injections into the pleural cavity, each containing 0.8 cubic centimetre of a three-per-cent. solution of hydrogen peroxide, were administered, but at the seventh the patient complained of faintness, the pulse failed, respiration became oppressed, and death occurred in ten minutes. As a local application to mucous membranes, the official solution should be used; the stronger solutions are sometimes too irritating. Hydrogen dioxide has been used to a considerable extent in the arts for bleaching and cleansing human hair, engravings, very fine textile fabrics, etc.

APPENDIX.

APOTHECARIES' WEIGHT—APOTHECARIES' MEASURE

FORMERLY OFFICIAL IN THE UNITED STATES PHARMACOPOEIA.

Pound,	\mathfrak{D}	=	12 Ounces.	Gallon,	\mathcal{C}	=	8 Pints.
Ounce,	\mathfrak{z}	=	8 Drachms.	Pint,	\mathcal{O}	=	16 Fluids.
Drachm,	\mathfrak{s}	=	3 Scruples.	Fluidounce,	$\mathfrak{f}\mathfrak{z}$	=	8 Fluids.
Scruple,	\mathfrak{d}	=	20 Grains.	Fluidrachm,	$\mathfrak{f}\mathfrak{s}$	=	60 Minims.
Grain,	gr.	=	1 Grain.	Minim,	\mathfrak{m}	=	1 Minim.

WEIGHTS AND MEASURES OF THE METRICAL OR FRENCH SYSTEM

NOW OFFICIAL IN THE UNITED STATES PHARMACOPOEIA.

MEASURES OF LENGTH.

One Myriametre	=	10,000 Metres.
One Kilometre	=	1,000 Metres.
One Hectometre	=	100 Metres.
One Decametre	=	10 Metres.
One METRE	=	the ten-millionth part of a quarter of the meridian of the earth
One Decimetre	=	the tenth part of one Metre, or 0.1 Metre.
One Centimetre	=	the hundredth part of one Metre, or 0.01 Metre; written Cm.
One Millimetre	=	the thousandth part of one Metre, or 0.001 Metre; written Mm.

WEIGHTS.

One Myriagramme	=	10,000 Grammes.
One Kilogramme	=	1,000 Grammes.
One Hectogramme	=	100 Grammes.
One Decagramme	=	10 Grammes.
One GRAMME	=	the weight of a cubic Centimetre of Water at 4° C.; written Gm
One Decigramme	=	the tenth part of one Gramme, or 0.1 Gramme.
One Centigramme	=	the hundredth part of one Gramme, or 0.01 Gramme.
One Milligramme	=	the thousandth part of one Gramme, or 0.001 Gramme.

MEASURES OF CAPACITY.

One Myrialitre	=	10 cubic Metres, or the measure of 10 Milliers of Water.
One Kilolitre	=	1 cubic Metre, or the measure of 1 Millier of Water.
One Hectolitre	=	100 cubic Decimetres, or the measure of 1 Quintal of Water.
One Decalitre	=	10 cubic Decimetres, or the measure of 1 Myriagramme of Water.
One LITRE	=	1 cubic Decimetre, or the measure of 1 Kilogramme of Water.
One Decilitre	=	100 cubic Centimetres, or the measure of 1 Hectogramme of Water.
One Centilitre	=	10 cubic Centimetres, or the measure of 1 Decagramme of Water.
One Millilitre	=	1 cubic Centimetre, or the measure of 1 Gramme of Water.

RELATION OF APOTHECARIES' WEIGHTS AND MEASURES TO EACH OTHER.

In distilled water at the temperature of 66°.

One Pound	=	0.7900031 Pint	=	6067.2238 Minims.
One Ounce	=	1.0533376 Fluidounces	=	505.6019 Minims.
One Drachm	=	1.0533376 Fluidrachms	=	63.2002 Minims.
One Scruple	=	...	=	21.0667 Minims.
One Grain	=	...	=	1.0533 Minims.
One Gallon	=	10.1265427 Pounds	=	68328.8862 Grains.
One Pint	=	1.2658178 Pounds	=	7291.1107 Grains.
One Fluidounce	=	0.9493633 Ounce	=	455.6944 Grains.
One Fluidrachm	=	0.9493633 Drachm	=	66.9618 Grains.
One Minim	=	...	=	0.0493 Grain.

RELATION OF APOTHECARIES' OR WINE MEASURE TO CUBIC MEASURE.

One Gallon	=	231.	Cubic Inches.	One Fluidrachm	=	0.22558 Cubic Inch.
One Pint	=	28.875	Cubic Inches.	One Minim	=	0.00375 Cubic Inch.
One Fluidounce	=	1.80468	Cubic Inches.
